

Probing the Myocardial Tissue Composition

Exhibition Hall

Monday 8:15 - 9:15

- 3095 **Computer 1** **Reducing magnetization-transfer-induced T1 estimation error in myocardial T1 mapping for the MOLLI sequence: simulation, phantom and in vivo studies**

 Jiaxin Shao¹, Dapeng Liu¹, Kyung Hyun Sung¹, Kim-Lien Nguyen², and Peng Hu¹
¹Radiology, University of California, Los Angeles, CA, United States, ²Division of Cardiology, University of California, Los Angeles, CA, United States
 The modified Look-Locker inversion-recovery (MOLLI) sequence is a widely used myocardial T1 mapping technique for tissue characterization. It is known that the MOLLI sequence underestimates myocardial T1 values (>10%) due to magnetization transfer (MT) effects and short myocardial tissue T2 values. In this work, we demonstrate that in vivo reduction of the inversion factor is predominantly responsible for the MT effect that reduces MOLLI T1 values. Thus, using an alternative T1 estimation algorithm with a measured inversion factor for the MOLLI sequence can reduce the MT effect on T1 estimation error.
-
- 3096 **Computer 2** **Ultrafast Cardiac Balanced Inversion Recovery with Interleaved Acquisition (UF-CABIRIA) for improved simultaneous T1 and T2 quantification of the heart at 3T.**

 Francesco Santini^{1,2}, Grzegorz Bauman^{1,2}, and Oliver Bieri^{1,2}
¹Division of Radiological Physics, University of Basel Hospital, Basel, Switzerland, ²Department of Biomedical Engineering, University of Basel, Basel, Switzerland
 CABIRIA is a method for the simultaneous quantification of T1 and T2 values of the myocardium. As other T1-quantification sequences, it relies on a bSSFP readout, and it is thus susceptible to off-resonance effects. In this work, we show an improvement over the CABIRIA method that reduces the TR and therefore increases the robustness towards field inhomogeneities. This method can potentially be extended to other quantification techniques.
-
- 3097 **Computer 3** **Quantitative Tissue Characterization by Magnetization Transfer-Weighted Cardiac MRI Detects Fibrosis Progression without Gadolinium in Patients with End Stage Renal Disease**

 Tori A Strom^{1,2}, Rebecca M Kidney², Tyler J Spear², Kristin N Andres³, Joshua C Kaine³, Steve W Leung⁴, and Moriel H Vandsburger^{1,2,5,6}
¹Physiology, University of Kentucky, Lexington, KY, United States, ²Cardiovascular Research Center, University of Kentucky, KY, United States, ³College of Medicine, University of Kentucky, KY, United States, ⁴Gill Heart Institute, University of Kentucky, KY, United States, ⁵Biomedical Engineering, University of Kentucky, KY, United States, ⁶Bioengineering, University of California Berkeley, Berkeley, United States
 Long term hemodialysis treatment for end stage renal disease (ESRD) is associated with a time dependent increase in cardiac death. The inability to use late gadolinium enhancement (LGE) cardiac MRI (CMR) in patients with renal dysfunction impedes the noninvasive monitoring of fibrosis progression and appropriate treatment selection in the population. We used magnetization transfer (MT) weighted CMR to monitor the progression of ventricular fibrosis over 1 year in patients with ESRD. While no major changes in hypertrophy or contractility were apparent, pervasive increases in myocardial signal was measured by MT-weighted CMR, consistent with reduced MT and progressive fibrosis development.
-
- 3098 **Computer 4** **Improved Detection of Right Ventricular Myocardial Infarction Using 3D Navigator-Gated Free Breathing Delayed Enhancement Cardiac Magnetic Resonance**

 Jiwon Kim¹, Tara Shah¹, Neil Mehta², Jonathan Weinsaft¹, Pascal Spincemaille³, Yi Wang³, and Thanh Nguyen³
¹Department of Cardiology, Weill Cornell Medical College, New York, NY, United States, ²Department of Medicine, Weill Cornell Medical College, New York, NY, United States, ³Department of Radiology, Weill Cornell Medical College, New York, NY, United States
 Right ventricular myocardial infarction (RV-MI) is a serious consequence of coronary artery disease that adversely affects outcomes. Conventional CMR employs 2D breath-held imaging (CMR_{BH}) to detect RV-MI, an approach that may sacrifice spatial resolution to enable patient breath-holds, and is thus suboptimal for imaging the RV. This study compared 3D navigator-gated free breathing CMR (CMR_{NAV}) to CMR_{BH} for detection of RV-MI in 75 post-MI patients. Results demonstrated a 2-fold increase in detection rate of RV-MI by CMR_{NAV}, accompanied by higher spatial resolution in 30% less scan time.
-
- 3099 **Computer 5** **Simultaneous Imaging of Myocardial Fat and Scar using Dark Blood Late Gadolinium Enhancement**

 Maryam Nezafat^{1,2}, Ahmed S Fahmy², Gifty Addae², and René M. Botnar¹
¹Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, ²Department of Medicine, Beth Israel Deaconess Medical Centre and Harvard Medical School, Boston, MA, United States
 Dark-Blood Late Gadolinium Enhancement (DB-LGE) sequence has been recently introduced to suppress the blood signal in order to enhance the contrast between blood and scar. However, it is difficult to distinguish scar from fat as both appear bright in DB-LGE images. In this study, we present a DB-LGE sequence that allows quantification of scar and fat volume in the heart in a single imaging sequence. Numerical simulation, phantom and in-vivo scans were performed to evaluate the proposed sequence.
-
- 3100 **3D high resolution imaging of human hearts for visualization of the cardiac structure**

Computer 6 Julie Magat¹, Valéry Ozenne¹, Fanny Vaillant¹, David Benoist¹, Marion Constantin¹, Virginie Dubes¹, Stephen Gilbert², Mark L. Trew³, Jérôme Naulin¹, Louis Labrousse⁴, Méléze Hocini⁴, Michel Haissaguerre⁴, Olivier Bernus¹, and Bruno Quesson¹

¹IHU LIRYC/U1045, Université de Bordeaux, Pessac, France, ²Mathematical Cell Physiology, Max Delbrück Center for Molecular Medicine, Berlin, Germany, ³Auckland Bioengineering Institute, University of Auckland, Auckland, New Zealand, ⁴IHU LIRYC/U1045, CHU Bordeaux, Pessac, France

The motivation of this study is to develop high resolution 3D MR imaging of human hearts to characterize the cardiac structure non-invasively. For this purpose, T1-weighted images and diffusion MRI in 3D from intact and infarcted hearts were acquired and analyzed to compare myocyte and myolaminar orientations in healthy and pathological regions.

3101

Computer 7 Improving precision of myocardial T₁ mapping with 3-parameter fit model using tissue characteristic-based denoising

Jihye Jang^{1,2}, Shiro Nakamori¹, and Reza Nezafat¹

¹Department of Medicine, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, United States, ²Department of Computer Science, Technical University of Munich, Munich, Germany

For the reconstruction of pixel-wise T₁ maps, 3-parameter fit model is highly accurate, but is sensitive to noise. Therefore, it is desirable to develop a robust method to reduce sensitivity to noise when 3-parameter fit model is used. In this work, we propose a robust denoising method based on tissue characteristics to improve precision of myocardial T₁ mapping. In phantom and in-vivo studies, denoising filtering provided similar T₁ measurements with significantly improved precision. This technique will make 3-parameter fit model more favorable by reducing sensitivity to noise and will allow for more accurate and precise myocardial T₁ mapping.

3102

Computer 8 Cine T1 Mapping: Look-Locker inversion recovery for phase resolved T1-Mapping with B₁+ Correction At 3T

Sebastian Weingärtner^{1,2,3}, Chetan Shenoy⁴, Lothar R. Schad³, and Mehmet Akçakaya^{1,2}

¹Electrical and Computer Engineering, University of Minnesota, Minneapolis, MN, United States, ²Center for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN, United States, ³Computer Assisted Clinical Medicine, Heidelberg University, Mannheim, Germany, ⁴Department of Cardiology, University of Minnesota, Minneapolis, MN, United States

Conventionally, evaluation of myocardial T₁-times is limited to a single snapshot of the cardiac cycle, leaving much of the dependence between functional and tissue characterization unstudied. Here, we propose an ECG-triggered steady-state Look-Locker technique that allows for functional, cardiac phase-resolved native T₁-mapping. Integratedly acquired phase-resolved B₁⁺-maps are used for T₁-time correction. High accuracy and good consistency of the T₁-times across cardiac phases is shown in phantom scans. In-vivo T₁-times show slight underestimation and similar precision compared to saturation-recovery T₁-mapping. High visual image quality at all cardiac phases is obtained at temporal resolutions up to 40ms in a single breath-hold.

3103

Computer 9 Active Shape Models Based Motion Correction for Myocardial T₁ Mapping

Hossam El-Rewaady¹, Shiro Nakamori¹, Gifty Addae¹, Warren Manning¹, and Reza Nezafat¹

¹Cardiovascular Division, Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States

A new framework based on Active Shape Models (ASM) is introduced to correct the motion artifacts induced by respiratory and cardiac motion in myocardial T₁ mapping. This framework includes three main steps: training ASM model to capture intensity variations of T₁ images at different inversion times, segmentation of T₁ weighted images using the trained model, and estimating and applying the registration parameters to correct for motion between images.

3104

Computer 10 A comparison of STEAM and spin echo diffusion tensor CMR in hypertrophic cardiomyopathy patients

Zohya Khaliq¹, Andrew Scott¹, Pedro Ferreira¹, Margarita Gorodezky¹, Ricardo Wage¹, Sonia NIELLES-Vallespin², David Firmin¹, and Dudley Pennell¹

¹NIHR Cardiovascular Biomedical Research Unit, Royal Brompton Hospital, LONDON, United Kingdom, ²National Heart Lung and Blood Institute, NIH, Bethesda, MD, United States

Diffusion tensor (DT) cardiovascular magnetic resonance (CMR) can provide myocardial microstructural information using either motion compensated spin echo (SE) or stimulated echo acquisition mode (STEAM) sequences. Here we present the first DT-CMR data from a cohort of hypertrophic cardiomyopathy patients using SE, and compare parameters obtained from SE and STEAM sequences at 3T in two phases of the cardiac cycle. We demonstrate that whilst reliability measures, diffusivity, and anisotropy differ between the sequences, both approaches are able to detect the sheetlet microstructure that is integral to wall thickening during cardiac contraction and shown to be aberrant in this condition.

3105

Computer 11 Identifying tissue changes of "normal-appearing" myocardium in pediatric myocarditis patients using quantitative T1 and T2 mapping techniques

Haipeng Wang¹, Bin Zhao², Cuiyan Wang¹, Tianyi Qian³, Guangbin Wang², Jing An⁴, Fei Gao², Andreas Greiser⁵, and Junyu Zhao⁶

¹Shandong Medical Imaging Research Institute, J'nan, People's Republic of China, ²Shandong Medical Imaging Research Institute, ³Siemens Healthcare, MR Collaborations NE Asia, Beijing, People's Republic of China, ⁴Siemens SSMR, APPL, ⁵Siemens Healthcare, Application Development, Erlangen, Germany, ⁶Shandong Provincial Qianfoshan Hospital

This study aimed to identify diffuse myocardial tissue changes in pediatric myocarditis patients by applying T1 and T2 mapping techniques. The correlations between T1 and T2 values and cardiac function were assessed. Abnormal post-contrast T1 values and extracellular volume (ECV) of "normal appearing" myocardium in pediatric myocarditis patients were found and were correlated with left ventricular cardiac function and stroke volume (SV) in children with chronic myocarditis.

3106

Computer 12

[The Effect of Mixing Time on Diffusion Spectrum Imaging of the Ex-vivo Porcine Heart](#)
Claudia Zanella¹, Christian T Stoeck¹, Constantin von Deuster¹, and Sebastian Kozerke¹

¹*Institute for Biomedical Engineering / University and ETH Zurich, Zurich, Switzerland*

Higher order diffusion imaging has revealed new insights into myocardial microstructure. At the b-values required for diffusion kurtosis or diffusion spectrum imaging, translation into human in-vivo application requires Stimulated Echo Acquisition Mode imaging (STEAM) at prolonged mixing-times. In this study the effect of mixing time on diffusion parameters is investigated covering the range of current spin-echo and STEAM approaches. Results show that fractional anisotropy increases and mean diffusivity decreases with mixing-time. Diffusional kurtosis was found to decrease with mixing-time by varying amounts along fiber, sheet and sheet-normal direction which needs to be considered when comparing spin-echo imaging with STEAM acquisitions.

3107

Computer 13

[Whole-heart T1 mapping using a 2D fat image navigator with 100% scan efficiency](#)

Giovanna Nordio¹, Gastao Cruz¹, Claudia Prieto¹, Torben Schneider^{1,2}, Rene M. Botnar¹, and Markus Henningson¹

¹*Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, London, United Kingdom,* ²*Philips Healthcare, Guildford Surrey, United Kingdom*

In this study a whole-heart saturation-recovery T1-mapping technique in combination with a fat image navigator (fat-iNAV) is proposed. Myocardial fat is imaged by the fat-iNAV to estimate respiratory motion. Each of the T1-weighted images are subsequently motion corrected prior to reconstruction of the T1 map. Fat-iNAV motion correction led to an improvement in myocardial borders delineation and accuracy of the myocardial T1 values, while there was a general underestimation of myocardial T1 in the non-motion corrected T1 maps (1115.4±110ms vs 998.6±101ms). Further work will investigate non-rigid motion correction and undersampled reconstruction for T1 mapping.

3108

Computer 14

[Accelerating High-Resolution Whole-Heart 3D T2 Mapping](#)

Dan Zhu¹, Haiyan Ding², Henry Halperin³, and Daniel A. Herzka¹

¹*Department of Biomedical Engineering, Johns Hopkins University School of Medicine, Baltimore, MD, United States,* ²*Department of Biomedical Engineering, Tsinghua University, Beijing, People's Republic of China,* ³*Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States*

In this work, we aim to determine an optimal strategy for accelerating high-resolution 3D myocardial T2 mapping. We quantitatively evaluate the performance of diverse methods involving different subsampling patterns and different reconstruction strategies relative to volume-by-volume SENSE reconstruction. Reconstructions which address all volumes as a single reconstruction problem (i.e. joint-sparsity SENSE or model-based SENSE) outperform volume-by-volume approaches, and variable density sampling outperforms equal spacing or CAIPRIHNA undersampling. The T2 values observed in parametric maps proved to be more sensitive to data corruption than images themselves, limiting the degree of data reduction tolerable.

3109

Computer 15

[In-vivo comparison of STEAM EPI and STEAM spiral diffusion-weighted sequences](#)

Margarita Gorodezky^{1,2}, Andrew D Scott^{1,2}, Pedro F Ferreira¹, Sonia Nielles-Vallespin³, Zohya Khaliq¹, Dudley J Pennell¹, and David N Firmin^{1,2}

¹*Cardiovascular Biomedical Research Unit, The Royal Brompton Hospital, London, United Kingdom,* ²*National Heart and Lung Institute, Imperial College, London, United Kingdom,* ³*National Heart, Lung and Blood Institute, National Institutes of Health, Bethesda, MD, United States*

A cardiac DTI STEAM spiral sequence with a novel asymmetric zonal excitation and a reduced FOV was implemented and compared to an established STEAM EPI sequence. 10 volunteers were scanned in systole and diastole and standard cDTI parameters were compared for both sequences. The spiral trajectory is both efficient and motion robust and its centre-out nature allows a shorter echo time and, therefore an increase in image SNR over EPI. The spiral trajectory is also able to take full advantage of the two-dimensional reduced in-plane field-of-view (FOV) made possible by the 3 RF pulses used in the STEAM sequence.

3110

Computer 16

[Biopsy-based calibration of T2* magnetic resonance for estimation of liver iron concentration](#)

Antonella Meloni¹, Filippo Leto², Daniele De Marchi¹, Vincenzo Positano¹, Laura Pistoia¹, Aurelio Maggio², and Alessia Pepe¹

¹*Fondazione G. Monasterio CNR-Regione Toscana, Pisa, Italy,* ²*Ospedale "V. Cervello", Palermo, Italy*

An excellent linear agreement between R2* values and cardiac iron measured with emission spectroscopy was found. The results further validate the current clinical practice of monitoring cardiac iron in vivo by CMR.

3111

Computer 17

[Myocardial Motion Velocity in Patients with Cirrhotic Cardiomyopathy](#)

Ting-Hsu Chen¹, Ming-Ting Wu², Mao-Yuan Su³, and Hsu-Hsia Peng¹

¹*National Tsing Hua University, Hsinchu, Taiwan,* ²*Department of Radiology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan,* ³*Department of Medical Imaging, National Taiwan University Hospital, Taipei*

In this study, we employed MR tissue phase mapping (TPM) to evaluate three-directional left ventricular velocity. The purpose of this study is to establish quantitative indices to comprehend the characteristics of myocardial motion in patients with cirrhotic cardiomyopathy. Compared with normal subjects, patients displayed lower systolic Vz and prolonged systolic TTPz. Lower systolic Vphi was also demonstrated in patient group. In conclusion, to analyze myocardial velocity and TTP can potentially provide helpful information for realizing the myocardial compensatory mechanism in patients with cirrhotic cardiomyopathy.

3112

Computer 18

Dependence of the Precision of Myocardial Late Gadolinium Enhancement Quantification on Inversion Time Selection Simulated Using Synthetic Inversion Recovery MR Imaging

Akos Varga-Szemes¹, Rob J van der Geest², U. Joseph Schoepf¹, Carlo N De Cecco¹, Taylor M Duguay¹, and Pal Suranyi¹

¹Department of Radiology and Radiological Science, Medical University of South Carolina, Charleston, SC, United States, ²Leiden University Medical Center, Leiden, Netherlands

Clinical late gadolinium enhancement (LGE) imaging of the myocardium requires inversion time (TI) optimization for adequate image quality. As the optimal TI (TI_0) depends on various factors, its influence on the precision of myocardial LGE quantification is of interest. In this study we aimed to prospectively investigate how the precision of LGE quantification varies in the clinically relevant TI range in 53 patients using T1-mapping-based synthetic inversion recovery (IR_{synth}) approach. We concluded that phase-sensitive IR_{synth} images provide precise quantification independent of TI, while magnitude IR_{synth} -based quantification is precise at TI_0 or longer TIs, but showing decreased precision below TI_0 .

3113

Computer 19

Precision and sensitivity of radial MOLLI sequence for fast myocardial T1 mapping

Benjamin Marty^{1,2}, Bertrand Coppa^{1,2}, and Pierre G Carlier^{1,2}

¹NMR Laboratory, Institute of Myology, Paris, France, ²NMR Laboratory, CEA, DRF, I³BM, MIRCen, Paris, France

Quantitative cardiac NMR imaging, and more particularly T1 mapping has become a most important modality to characterize myocardial tissue. In this work, we evaluated the precision and sensitivity of a fast radial MOLLI sequence by comparison with conventional MOLLI on 14 subjects presenting different heart rates, BMI and cardiac conditions. This sequence demonstrated the same precision on T1 estimates than conventional MOLLI, and was not influenced by heart rate variations. It might represent a good candidate for ultra-fast acquisition of myocardial T1 maps.

3114

Computer 20

Temporal Diffusion Spectroscopy in the Heart with Oscillating Gradients

Irvin Teh¹, Jürgen E. Schneider¹, Hannah J. Whittington¹, Tim B. Dyrby^{2,3}, and Henrik Lundell²

¹Division of Cardiovascular Medicine, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom, ²Danish Research Centre for Magnetic Resonance, Centre for Functional and Diagnostic Imaging and Research, Copenhagen University Hospital Hvidovre, Denmark, ³Department of Applied Mathematics and Computer Science, Technical University of Denmark, Denmark

Conventional pulsed gradient spin echo, with its longer diffusion time, is poorly sensitive to diffusion at short length scales. Oscillating gradient spin echo enables assessment of diffusion at sub-cellular length scales, providing information about cell size and the intracellular environment. We observed that time dependence of diffusion in the myocardium was more pronounced along the 2nd and 3rd eigenvectors compared to the 1st eigenvector of the diffusion tensor. This is consistent with known anisotropic cardiomyocyte geometry. Furthermore, the measured diffusion at high frequencies still exhibited strong anisotropy that may reflect anisotropy of intracellular organelles such as actin-myosin filaments.

3115

Computer 21

Cardiac CEST MRI with Dual-Echo Readout for B₀ Correction: A Preliminary Reproducibility Study for Assessment of Metabolic Activity in the Heart

Zhengwei Zhou^{1,2}, Xiaoming Bi³, and Debiao Li^{1,2}

¹Biomedical Imaging Research Institute, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ²Department of Bioengineering, University of California, Los Angeles, Los Angeles, CA, United States, ³MR R&D, Siemens Healthcare, Los Angeles, CA, United States

Previous studies have shown that cardiac CEST technique can detect myocardial metabolic abnormalities in chronic myocardial infarction. However, this navigator-gated technique is still sensitive to B₀ field variations caused by respiratory motion within the acceptance window.

In this work, we developed a cardiac CEST dual-echo technique which not only acquires CEST-weighted image, but also enables acquisition of B₀ map for each saturation frequency offset. The reproducibility of this technique was also assessed.

3116

Computer 22

Dynamic Nitroxide-Enhanced MRI Detects Oxidative Stress in the Hearts of Mice Subject to Angiotensin II Infusion

Sophia Xinyuan Cui¹, Rene J. Roy², Brent A. French^{1,2}, and Frederick H. Epstein^{1,2}

¹Biomedical Engineering, University of Virginia, Charlottesville, VA, United States, ²Radiology, University of Virginia, Charlottesville, VA, United States

Oxidative stress contributes importantly to the pathophysiology of many types of cardiovascular disease. Nitroxides are relatively stable free radicals that have been used as redox-sensitive MRI contrast agents in preclinical studies to assess tumor redox status. We implemented a dynamic nitroxide-enhanced MRI method to test the hypothesis that MRI can detect cardiac oxidative stress in vivo. Imaging was performed in untreated controls and mice infused with angiotensin II for 7 days. The MRI signal decay rate in the heart was significantly higher in the angiotensin II group, indicating that these methods detect cardiac oxidative stress due to angiotensin II infusion.

Estimation of motion-corrupted data using parallel imaging for carotid artery vessel wall imaging

Robert Frost^{1,2,3}, Luca Biasioli⁴, Linqing Li⁵, Aaron T. Hess⁴, and Peter Jezzard³

¹Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Charlestown, MA, United States, ²Department of Radiology, Harvard Medical School, Boston, MA, United States, ³FMRIB Centre, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom, ⁴Oxford Centre for Clinical Magnetic Resonance Research, Division of Cardiovascular Medicine, University of Oxford, Oxford, United Kingdom, ⁵Section on Magnetic Resonance Spectroscopy, National Institute of Mental Health, Bethesda, MD, United States

Carotid artery imaging is hampered by motion artefacts, including those caused by occasional swallowing motion. In this work, we extend previous work on intelligent reacquisition to estimate and replace motion-corrupted data. 'Bad' phase-encode lines were synthesized from surrounding 'good' lines using parallel imaging techniques. Estimation and replacement of corrupted data reduced background ghosting levels in comparison to the previous reacquisition approach. A small number of reacquisitions was maintained to ensure good quality data at the centre of k-space because these are essential for image quality and for calibration of the parallel imaging-based estimation.

3118

Computer 26

Three-dimensional black-blood multi-contrast protocol for carotid imaging using compressed sensing: a repeatability study

Jianmin Yuan¹, Ammara Usman¹, Scott A. Reid², Kevin F. King³, Andrew J. Patterson⁴, Jonathan H. Gillard¹, and Martin J. Graves^{1,4}

¹Department of Radiology, University of Cambridge, Cambridge, United Kingdom, ²GE Healthcare, Amersham, United Kingdom, ³GE Healthcare, Waukesha, Wisconsin, United States, ⁴Department of Radiology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Multi-contrast black-blood MRI protocol has demonstrated the ability to assess carotid plaque vulnerability. Current limitation for its wide application is the long scanning time. The purpose of this work is to evaluate the repeatability of a compressed sensing (CS) accelerated multi-contrast protocol at 3T.

3119

Computer 27

3D black blood T2 mapping of the carotid artery wall with compressed sensing and data-driven parallel imaging

Jianmin Yuan¹, Ammara Usman¹, Scott A. Reid², Kevin F. King³, Andrew J. Patterson⁴, Jonathan H. Gillard¹, and Martin J. Graves^{1,4}

¹Department of Radiology, University of Cambridge, Cambridge, United Kingdom, ²GE Healthcare, Amersham, United Kingdom, ³GE Healthcare, Waukesha, Wisconsin, USA, ⁴Department of Radiology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Quantitative MRI has many advantages over traditional contrast weighted methods, which may be more suitable for multi-centre studies across different MRI systems. This study describes the development of a 3D black blood T₂ mapping sequence with the combination of compressed sensing and data-driven parallel imaging. Phantom and volunteer experiments were performed to optimise the parameters and patients with atherosclerotic carotid artery disease were scanned using the optimised sequence.

3120

Computer 28

Whole-brain vessel wall imaging within 5 minutes using compressed sensing accelerated IR-SPACE

Zhaoyang Fan¹, Xiaoming Bi², Marcel Maya³, Qi Yang^{1,4}, Shlee Song⁵, Nestor Gonzalez⁶, Schlick Konrad⁵, Esther Raithe⁷, Christoph Forman⁷, Gerhard Laub², and Debiao Li¹

¹Biomedical Imaging Research Institute, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ²Siemens Healthcare, Los Angeles, CA, United States, ³Imaging, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ⁴Xuanwu Hospital, Beijing, People's Republic of China, ⁵Neurology, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ⁶Neurosurgery, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ⁷Siemens Healthcare, Erlangen, Germany

Inversion-recovery (IR) prepared SPACE was recently proposed as a whole-brain intracranial vessel wall imaging technique. This work aimed to investigate the feasibility of accelerating the scan from 8 min to <5 min using compressed sensing (CS). A prototype CS IR-SPACE sequence was implemented on a 3T system. Wavelet sparse regularization (λ) and iteration (Iter) were optimized for the scenario of sampling 15% of k-space data based on a volunteer study. Image quality was visually comparable between CS IR-SPACE and regular IR-SPACE scans. In addition, CS IR-SPACE and IR-SPACE showed comparable lesion delineation quality in patients despite markedly different scan times.

3121

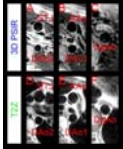

Computer 29

Endothelial permeability in the aortic root of atherosclerotic mice: quantification using 3 dimensional, black blood, self-gated T1 mapping

Alison Pruzan¹, Arthi Sridhar¹, Gustav Strijkers^{1,2}, Zahi A. Fayad¹, and Claudia Calcagno¹

¹Translational and Molecular Imaging Institute, Icahn School of Medicine at Mount Sinai, New York, NY, United States, ²Academic Medical Center, Amsterdam, Netherlands

Atherosclerotic plaques prone to rupture are characterized by endothelial dysfunction and increased endothelial permeability. The aortic root is a vascular territory where permeable atherosclerotic plaques form consistently and reliably. However, morphological and quantitative parametric imaging of the mouse aortic root is very challenging, due to the small dimensions, rapid blood flow through the valves, and high heart rate. Here we demonstrate feasibility of pre and post-contrast T1 mapping of the mouse aortic root using a 3 dimensional, self-gated fast low angle shot (FLASH) sequence with black blood imaging for improved vessel wall delineation. Future studies will entail further development of this technique for the more accurate quantification of endothelial permeability and fractional blood volume in the mouse aortic root.

- 3122 **Computer 30** [Quantitative Multi-Contrast Atherosclerosis Characterization \(qMATCH\): Comprehensive Quantitative Evaluation of Atherosclerosis in a Single-Scan](#)
 Yibin Xie¹, Anthony Christodoulou¹, Nan Wang^{1,2}, and Debiao Li¹
¹Biomedical Imaging Research Institute, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ²Department of Bioengineering, University of California, Los Angeles, Los Angeles, CA, United States
- Although MRI is an attractive imaging modality for the evaluation of carotid atherosclerosis thanks to its versatility and noninvasiveness, its current clinical usage is still limited. Major drawbacks of conventional protocols include long scan time and observer variability due to the qualitative nature of the images. In this work we proposed a fast, 3D, quantitative, multi-contrast MRI technique, qMATCH, for a comprehensive evaluation of carotid atherosclerosis in less than 8 minutes. Preliminary results from phantom and in vivo studies demonstrated excellent image quality and reliable quantification of tissue relaxation times.
-
- 3123 **Computer 31** [Aortic Vessel Wall Imaging Using 3D Phase Sensitive Inversion Recovery in Children and Young Adults](#)
 Animesh Tandon^{1,2}, Tarique Hussain^{1,2}, Andrew Tran³, René M Botnar⁴, Gerald F Greil^{1,2}, and Markus Henningson⁴
¹Pediatrics, Radiology, BME, University of Texas Southwestern Medical Center, Dallas, TX, United States, ²Pediatric Cardiology, Children's Medical Center Dallas, Dallas, TX, United States, ³Pediatrics, University of Texas Southwestern Medical Center, Dallas, TX, United States, ⁴Biomedical Engineering, King's College, London, London, United Kingdom
- Currently, T2-weighted TSE black blood zoom imaging (T2Z) is used to visualize atherosclerosis, but volumetric, high isotropic resolution datasets would be preferable. We compared aortic luminal sharpness (ALS) of a novel 3D bSSFP phase-sensitive inversion recovery black blood sequence (3DPSIR) to T2Z in 10 children and young adults with familial hypercholesterolemia at 5 aortic locations. 3DPSIR sequence duration was 7.0 minutes compared to 11.4 minutes for T2Z with no significant difference in ALS overall. 3DPSIR high resolution volumetric datasets will enable rapid, detailed 3D vessel wall imaging in children and young adults, allowing improved exploration of vascular health.
-
- 3124 **Computer 32** [Quantitative T1 and T2* carotid atherosclerotic plaque imaging using 3D multi-echo phase-sensitive inversion recovery sequence: a feasibility study](#)
 Yasuhiro Fujiwara¹, Hirotohi Maruyama², Kanako Toyomaru³, Yuri Nishizaka³, Kazuma Yamasaki³, and Masahiro Fukamatsu⁴
¹Department of Medical Imaging, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan, ²Radiological Center, National Hospital Organization Kumamoto Saisyunsou Hospital, Kumamoto, Japan, ³Graduate School of Health Sciences, Kumamoto University, Kumamoto, Japan, ⁴Radiological Center, National Hospital Organization Kumamoto Medical Center, Kumamoto, Japan
- A quantitative evaluation of plaques is required in MR plaque imaging. The purpose of this study was to determine whether the 3D multi-echo Phase-Sensitive Inversion Recovery sequence can improve the T1 intra-plaque hemorrhage (IPH)-to-muscle contrast while simultaneously providing accurate T1 and T2* values for an IPH. This sequence may have potential to improve plaque MR imaging and make it possible to obtain detailed information about the components of carotid atherosclerotic plaques.
-
- 3125 **Computer 33** [Quantitative Evaluation of RECS-3D MERGE MR Imaging for Carotid Plaque Assessment](#)
 Bo Li^{1,2}, Hao Li³, Guofu Huang¹, Xia Qian¹, Wei Wang¹, and Li Dong⁴
¹Center Laboratory, The First Hospital of Nanchang City, Nanchang, People's Republic of China, ²Department of Radiology, The Third Affiliated Hospital of Nanchang University, Nanchang, People's Republic of China, ³Department of Radiology, University of Cambridge, Cambridge, United Kingdom, ⁴Department of Radiology, Beijing Anzhen Hospital, Beijing, People's Republic of China
- We sought to quantitatively investigate the performances on blood suppression efficiency, wall-lumen CNR and plaque burden measurements for the RECS-3D MERGE sequence in carotid vessel wall MR imaging.
- Twelve patients with carotid artery stenosis were recruited in this study. Lumen SNR and wall-lumen CNR were calculated and plaque burden measurements (i.e., lumen area, wall area, mean wall thickness and maximum wall thickness) were measured.
- The RECS-3D MERGE was quantitatively demonstrated to have the ability to provide the comparable blood suppression, black-blood image quality and the highly correlated morphometry with the current plaque imaging protocol. The RECS-3D MERGE could be a promising tool for plaque burden measurement in a short scan time.
-
- 3126 **Computer 34** [Evaluation of Four Injection Strategies for High Spatial Resolution Gadobenate Dimeglumine-Enhanced MR Angiography](#)
 Gregory J Wilson¹ and Jeffrey H Maki¹
¹Radiology, University of Washington, Seattle, WA, United States
- Four injection profiles were evaluated in 40 subjects (10 each). The profiles were designed to provide a signal intensity plateau for a 20 second contrast-enhanced MR angiography scan, using gadobenate dimeglumine. The injection profiles were: 1) standard, non-diluted, 1.6 mL/sec; 2) diluted, 1.6 mL/sec; 3) diluted, bi-phasic, and 4) diluted, patient-tailored. All subjects received a total dose of 0.1 mmol/kg, divided between a test bolus and a full bolus. The "diluted" protocols included dilution of the total dose to 40 mL with normal saline. Signal intensity profiles were measured and analyzed for width of plateau (FW80M) and peak signal intensity.
-
- 3127 **Computer 35** [3D segmentation of the Pulmonary Arteries on Magnetic Resonance Angiography](#)
Christopher S Johns¹, Alberto Biancardi^{1,2}, Guilhem J Collier¹, David A Capener¹, Andy J Swift^{1,2}, and Jim M Wild¹
¹Academic Radiology, The University of Sheffield, Sheffield, United Kingdom, ²Insigneo, Institute of In-Silico Medicine, Sheffield, United Kingdom

Contrast enhanced magnetic resonance angiography (MRA) is in common use in the assessment of pulmonary hypertension. We present a novel method for segmentation of the pulmonary arteries allowing rapid assessment of the proximal pulmonary arteries down to the 4th generation. Whilst the strongest correlation with mean pulmonary artery pressure was with the right main pulmonary artery, the torsion of the 4th generation pulmonary arteries was also associated with increasing mean pulmonary artery pressure. We hope quantitative vessel segmentation will improve our understanding of the impact of proximal pulmonary arterial remodelling in pulmonary hypertension.

The value of 3T contrast-enhanced whole-heart Coronary MRA in a integrated assessment of Cardiac Magnetic Resonance Protocol for Detection of suspected or known Coronary Artery Disease

lijun zhang¹, Yi He¹, Zhan ming Fan¹, and Debiao Li²

¹Radiology Department, Beijing Anzhen Hospital, Capital Medical University, Beijing, People's Republic of China, ²Cedars-Sinai Medical Center, Biomedical Imaging Research Institute, University of California, Los Angeles, United States

We try to evaluate the additive diagnostic value of a 3T whole-heart CE-MRCA integration into a CMR-MPI/LGE protocol for the detection of coronary artery disease. A total of 38 subjects were examined by CMR (including CMR-MPI, MRCA, and LGE)[j1] and x-ray invasive coronary angiography (ICA). Diagnostic performances of MRCA, CMR-MPI/LGE, and MRCA+CMR-MPI/LGE integration were determined having XA as standard for coronary artery disease. In per-vessel analysis, integrated protocol (AUC=0.84) performed better than the isolated CMR-MPI/LGE (AUC=0.63). In this suspected or known coronary artery disease population, integration of CE-MRCA significantly improved per-vessel diagnostic accuracy of a comprehensive 3T CMR-MPI/LGE protocol.

A novel method for performing percutaneous transluminal renal angioplasty with the guide of non-contrast magnetic resonance angiography overlaid on fluoroscopy images

Yoshiaki Morita¹, Tetsuya Fukuda¹, Yoshiaki Watanabe¹, Tatsuya Nishii¹, Atsushi Kono¹, and Naoaki Yamada¹

¹Department of Radiology, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan

Herein, we present a new method for the performance of percutaneous transluminal renal angioplasty (PTRA) guided by non-contrast magnetic resonance angiography (NATIVE True FISP) overlaid on intra-procedural fluoroscopy images. This novel overlay system led to sufficient visualization as the overlaid vasculature on the live fluoroscopic image, and enabled the safe completion of PTRA with fewer angiographic procedures, thus requiring lower volumes of iodinated contrast material and shorter fluoroscopic times.

Velocity-selective unenhanced peripheral MR angiography: Initial clinical testing compared with digital subtraction angiography

Tae-hoon Shin¹, Rajiv G Menon², Devin Watson³, Rajabrata Sarkar³, Sanjay Rajagopalan⁴, and Robert Crawford³

¹Diagnostic Radiology and Nuclear Medicine, University of Maryland, Baltimore, MD, United States, ²New York University, New York, NY, United States, ³Vascular Surgery, University of Maryland, Baltimore, MD, United States, ⁴Cardiovascular Medicine, Case Western Reserve, Cleveland, OH, United States

We performed initial clinical testing of velocity-selective magnetization-prepared MR angiography (VS-MRA) in 31 patients with peripheral arterial disease with digital subtraction angiography (DSA) serving as the reference standard. The image quality score of VS-MRA was 2.8 ± 0.6 in the scale of 0-3 (0: non-diagnostic, 3: excellent). The sensitivity and specificity for detecting significant stenosis were 90.1% and 96.2%, respectively on a per-segment basis (n=286), and were 92.7% and 92.0%, respectively on a per-region basis (n=105). The Fleiss-Cohen κ value for the agreement between VS-MRA and DSA was 0.91 on a per-segment basis and 0.88 on a per-region basis.

Computer 39

Super-Resolution Intracranial Quiescent-Interval Slice-Selective Magnetic Resonance Angiography

Ioannis Koktzoglou^{1,2}, Shivraman Giri³, Jianing Pang³, Jeremy D Collins⁴, and Robert R Edelman^{1,4}

¹Radiology, NorthShore University HealthSystem, Evanston, IL, United States, ²Radiology, University of Chicago Pritzker School of Medicine, Chicago, IL, United States, ³Siemens Healthineers, Chicago, IL, United States, ⁴Radiology, Northwestern University Feinberg School of Medicine, Chicago, IL, United States

We evaluated whether super-resolution reconstruction could be used to improve the vascular detail of quiescent-interval slice-selective (QISS) MRA of the intracranial circulation. Results suggest that super-resolution reconstruction can substantially improve intracranial arterial delineation without the signal-to-noise ratio penalty of directly acquiring thin-slice images.

Simultaneous Bright and Black Blood Whole Heart Phase Sensitive Inversion Recovery (PSIR) for Non Contrast Enhanced Coronary Lumen and Plaque Characterization

Giulia Ginami¹, Radhouene Neji², Rene Botnar¹, and Claudia Prieto¹

¹Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, ²MR Research Collaborations, Siemens Healthcare Limited, Frimley, United Kingdom

This study introduces a 3D whole-heart sequence with image-based navigation for non-contrast enhanced coronary lumen and coronary thrombus/haemorrhage characterization. The sequence is based on a phase sensitive inversion recovery (PSIR)-like approach enabling the acquisition of two bright-blood datasets for visualization of the coronary lumen and estimation of motion parameters. Furthermore, a third, fully co-registered dark-blood dataset for thrombus/haemorrhage characterization is obtained from the PSIR reconstruction. With the proposed approach the coronary lumen is visualized with improved SNR/CNR and vessel sharpness when compared to a conventional T2 prepared coronary MRA acquisition. In addition, effective blood signal suppression and feasibility for thrombus visualization is shown with the PSIR reconstructed black-blood dataset.

¹Chongqing Medical University, Chongqing, People's Republic of China, ²Department of Biomedical Engineering, School of Medicine, Tsinghua University, ³Department of Biomedical Engineering, School of medicine, Tsinghua University, Beijing, People's Republic of China
- The purpose of this study is to evaluate the ability of SNAP to evaluate the CoW by comparing with an established non-contrast MRA technique, time of flight (TOF). We found SNAP have good agreement with TOF and similar intra-reader reproducibility in CoW evaluation. However, the agreement between TOF and SNAP and the reproducibility of each technique is moderate in the anterior communicating artery identification. Thus, SNAP shows great promise for imaging both intracranial artery and vessel wall with a single scan.

- 3134 **Computer 42** [Flow enhanced \(FEED\) Arterial Spin Labeling Angiography with segmented Zero Echo Time Readout](#)

 Jianxun Qu¹, Bing Wu¹, and Zhenyu Zhou¹
¹MR Research China, GE Healthcare, Beijing, People's Republic of China
- ASL based MRA with continuous labeling has the optimal label efficiency. To achieve data acquisition efficiency, a long readout train is frequently used after labeling. Flow void might appear due to the lack of tagged blood entering the imaging volume during readout. A method named hybrid ASL address this problem with additional pulsed inversion. Yet, blood inverted by pulsed ASL still experiences considerable T1 decay during readout. We propose a method termed flow enhanced ASL (FEED). Interleaved labeling modules along with segmented readout was employed. As the results show, FEED could increase the signal level without prolonging scan time.
-
- 3135 **Computer 43** [Free-breathing non-contrast 3D radial respiratory motion-resolved versus motion-corrected whole-heart coronary MRA at 3T](#)

 Jessica AM Bastiaansen¹, Lorenzo di Sopra¹, Jérôme Yerly^{1,2}, Davide Piccini³, Ruud B van Ooijen¹, and Matthias Stuber^{1,2}
¹Department of Radiology, Hospital Lausanne (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland, ²Center for Biomedical Imaging, Lausanne, Switzerland, ³Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, Switzerland
- Coronary MRA performed using respiratory self-navigation techniques that apply retrospective motion-correction suffer from artifacts originating from static anatomical structures surrounding the heart. This becomes even more complicated at 3T due to insufficient fat suppression. Here we implemented free-breathing self-navigated 3D coronary MRA at 3T. Instead of using a motion model, we resolved the motion using 4D k-t sparse SENSE. Resulting images were then quantitatively compared with those reconstructed from the same datasets but using a 1D motion correction. We demonstrate that non-contrast whole-heart coronary MRA can be performed at 3T and that 4D motion-resolved reconstruction effectively minimizes adverse effects of respiratory-motion.

¹Pediatric Cardiology, UT Southwestern Medical Center Dallas, Dallas, TX, United States, ²Pediatric Cardiology, Children's Health, Children's Medical Center Dallas, Dallas, TX, United States, ³Division of Imaging Sciences, King's College London
- Dual phase whole heart imaging allows accurate depiction of cardiac segmental anatomy for congenital heart disease. We applied image-based navigation (iNAV) to improve its clinical utility. Qualitative and quantitative image quality scoring showed that iNAV gave equivalent image quality compared to the standard respiratory navigator. However, the distal coronary arteries were better visualized and the sequence duration was shorter. Using dual-phase iNAV, complete segmental anatomy was delineated in 27/30 patients (90%). The use of iNAV dual phase 3D SSFP whole heart acquisition allows complete morphological diagnosis for congenital heart disease with high image quality with more clinically acceptable time constraints.

- In this study, we investigated the feasibility of accelerating a recently proposed arterial spin labeling (ASL) based, time-resolved non-contrast enhanced dynamic MR angiography (NCE-dMRA) technique using parallel imaging and compressed sensing. By taking advantage of the inherent and unique "subtraction sparsity" in ASL type acquisition, we combined a recently developed CS technique, which uses a magnitude subtraction to enhance sparsity in MRA data, with the ESPIRiT method for SENSE type PI reconstruction. Proposed method was compared with the previously used KWIC reconstruction to demonstrate its advantage in reducing temporal blurring caused by view-sharing.
-
- 3138 **Computer 46** [Single-Shot Coronary QISS MRA in Children using Radial k-Space Sampling and Compressed Sensing](#)

 Daming Shen¹, Robert R. Edelman², Joshua D Robinson³, Hassan Haji-Valizadeh¹, Shivraman Giri⁴, Ioannis Korktzoglou², Cynthia K. Rigby³, and Daniel Kim³
¹Biomedical Engineering, Northwestern University, Chicago, IL, United States, ²Department of Radiology, NorthShore University HealthSystem, Evanston, IL, United States, ³Department of Radiology, Northwestern University, Chicago, IL, United States, ⁴Cardiovascular MR R&D, Siemens Healthineers, Chicago, IL, United States

Coronary MRA is complex to set up (e.g., navigator gating to track respiratory motion), typically takes 5-10 min to complete, and often produces inconsistent results. Quiescent-Interval Slice-Selective (QISS) MRA is a promising method for rapid coronary imaging. We sought to develop a single-shot (real-time) coronary QISS MRA using compressed sensing.

Computer 47

[Automated Coronary Artery Ostia Detection in Magnetic Resonance Angiography](#)

Bernhard Stimpel¹, Christoph Forman², Jens Wetzl^{1,3}, Michaela Schmidt², Andreas Maier^{1,3}, and Mathias Unberath^{1,3}

¹Pattern Recognition Lab, Department of Computer Science, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, ²Magnetic Resonance, Siemens Healthcare GmbH, Erlangen, Germany, ³Erlangen Graduate School in Advanced Optical Technologies (SAOT), Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

Anomalies of the coronary ostia can have severe consequences. To provide a screening solution, automated ostia detection based on single breath-hold coronary MRA scans is presented. The aorta is segmented in the data sets to serve as an orientation point and vesselness enhancing filters are applied. Searching the aorta surface for high vessel responses by a ray-tracing procedure yields information about the position of the coronary ostia. The proposed approach was successfully validated in 10 volunteers with an average deviation of 7.6° in angular and 1.2 mm in superior-inferior direction.

[Age-stratified normal left atrial deformation assessed by novel longitudinal strain parameters on a 3T MR scanner](#)

Shuang Leng¹, Xiaodan Zhao¹, Angela Su-Mei Koh^{1,2}, Ru San Tan^{1,2}, and Liang Zhong^{1,2}

¹National Heart Centre Singapore, Singapore, Singapore, ²Duke-NUS Medical School Singapore, Singapore, Singapore

The aim of this study was to examine the age-related normal left atrial (LA) longitudinal deformation by a novel and fast assessable strain parameter with standard cardiac magnetic resonance (CMR) imaging. A total of 60 healthy subjects (30 males, age between 20 and 80 years) were categorized by age into young, middle-aged, and elderly adults. The LA longitudinal strain and strain rate measurements corresponding to reservoir and conduit phases were negatively related to age, while no significant age-dependency was observed for LA contraction strain and strain rate values. These strain parameters can be used to evaluate LA deformation and functionality.

[Right ventricular deformation by CMR feature tracking in patients with volume-overload and pressure-overload congenital heart diseases](#)

Shuang Leng¹, Xiaodan Zhao¹, Wen Ruan¹, Ru San Tan^{1,2}, Ju Le Tan^{1,2}, and Liang Zhong^{1,2}

¹National Heart Centre Singapore, Singapore, Singapore, ²Duke-NUS Medical School Singapore, Singapore, Singapore

Two major patterns of right ventricular (RV) overload are volume overload and pressure overload. This study aimed to investigate the differences of RV myocardial deformation associated with volume and pressure overload congenital heart diseases. Cardiac magnetic resonance feature tracking was applied to RV 4-chamber and short axis view in a subject group comprising 23 patients with repaired tetralogy of Fallot (rTOF), 23 patients with pulmonary hypertension (PH), and 23 age- and gender-matched normal controls. Results indicated that PH patients had most diminished RV longitudinal and circumferential strain. Patients with rTOF had reduced RV longitudinal strain but higher circumferential strain.

[Accelerated Cardiac Cine "Watermark" MRI provides Cardiac Function via Magnitude Cine and 2D Myocardial Strain via Spatially Modulated Phase](#)

Ronald J Beyers¹, Davis M Vigneault^{2,3,4}, Nouha Salibi^{1,5}, David A Bluemke⁴, and Thomas S Denney¹

¹MRI Research Center, Auburn University, Auburn, AL, United States, ²Department of Engineering Science, University of Oxford, Oxford, United Kingdom, ³Sackler School of Graduate Biomedical Sciences, School of Medicine, Boston, MA, United States, ⁴Radiology and Imaging Sciences, National Institutes of Health, Bethesda, MD, United States, ⁵MR R&D, Siemens Healthcare, Malvern, PA

We developed a parallel imaging accelerated Cine Watermark (CWM) sequence to provide normal cine magnitude images plus phase image-only multi-directional spatial encoding for quantitative cine strain – while requiring no extra operator effort. Spatial cosine modulation post-processed by complex image sum/differencing produced separate normal magnitude cine and unique phase-only spatial modulation for strain calculation. *In vivo* human scans demonstrated good magnitude cine and phase-only quantified displacement. Cardiac strains were tracked by a novel non-linear least squares method combining quadratic b-spline contours, nearest neighbor optimized phase tracking, and physically-motivated regularizers. Cardiac left ventricular, short-axis, circumferential strain results agreed with previous literature.

Left ventricular-arterial coupling and mechanical efficiency assessed by pressure-volume loop in pulmonary artery hypertension patients

Xiaodan Zhao¹, Fei Xu², Xiaoke Shang^{3,4}, Yang Dong², Wen Ruan¹, Gangcheng Zhang⁵, Ru San Tan^{1,6}, Ju Le Tan^{1,6}, Yucheng Chen², and Liang Zhong^{1,6}

¹National Heart Centre Singapore, Singapore, Singapore, ²West China Medical Centre of Sichuan University, People's Republic of China, ³Wuhan Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, People's Republic of China, ⁴Department of Cardiology, Second Clinical College of Wuhan University, Wuhan, People's Republic of China, ⁵WuHan Asia Heart Hospital, People's Republic of China, ⁶Duke-NUS Medical School Singapore, Singapore, Singapore

Left ventricular end-systolic elastance (Ees), arterial elastance (Ea) and ventricular arterial coupling (VAC) (ratio of Ea/Ees) has been considered "gold" standard to assess ventricular contractility and performance. Ventricular arterial uncoupling due to impaired Ees or augmented Ea impaired ventricular mechanical efficiency (ME) and cardiac output. Ventricular contractility and arterial loading and the degree of their mismatching have yet been studied in pulmonary hypertension (PH). A total of 42 PH subjects who underwent both cardiac magnetic resonance (CMR) and right heart catheterization (RHC) were categorized into three groups – preserved LV ejection fraction (LVEF > 50%) and VAC < 0.8 (group 1); preserved LVEF and VAC > 0.8 (group 2); reduced LVEF (< 50%) (group 3). The results showed that VAC was correlated negatively with ME, which indicated arterial-ventricular uncoupling impaired mechanical efficiency. Importantly, the group 2 with ventricular arterial uncoupling had impaired mechanical efficiency despite its preserved ejection fraction.

Cardiac function relation to preload variation based on free breathing motion

Teodora Chitiboi¹, Rebecca Ramb¹, Eve Piekarski², Li Feng¹, Anja Hennemuth³, and Leon Axel¹

¹Radiology, New York University School of Medicine, New York, NY, United States, ²Nuclear Medicine Ward, Pitié Salpêtrière Hospital, Paris, Paris, France, ³Fraunhofer MEVIS, Germany

Free-breathing cardiac cine MRI provides novel information on cardiac dynamics. In this work, we investigate the relation between cardiac function and left-ventricular preload variations induced by respiratory motion, in normal subjects and patients. We used the left-ventricular diameter perpendicular to the septum as a measure of preload and the relative change in diameter between end-systole and end-diastole as a measure of functional response. There was a significantly larger change in diameter during the respiratory cycle for normal subjects compared to patients. We also found a significant correlation between preload and cardiac function for normal subjects, which was reduced for patients.

3146

Computer 55

Quantitative Evaluation of Ultra-fast Real Time Imaging Compared to Cine at 1.5 T and Demonstration of Clinical Value in Atrial Fibrillation

Aaron T Hess¹, Betty Raman¹, Joana Leal¹, Adam Lewandowski², Jane Francis¹, Masliza Mahmud¹, Dirk Voit³, Markus Untenberger³, Jens Frahm³, Stefan Neubauer¹, and Matthew David Robson¹

¹OCMR, Oxford University, Oxford, United Kingdom, ²RDM, Oxford University, Oxford, United Kingdom, ³Biomedizinische NMR Forschungs GmbH, Max-Planck-Institut für biophysikalische Chemie, Göttingen, Germany

Ultra-fast real time imaging allows cine imaging of the whole heart without gating or breath-holding in around 1 minute. Here clinical cardiac metrics are evaluated and compared with those from a standard clinical acquisition in normal volunteers. We find agreement adequate for clinical use. The real time approach is evaluated in a case of atrial fibrillation and found to provide a more robust evaluation of cardiac parameters in a shorter acquisition time.

3147

Computer 56

UNFOLDED spiral SPIRIT TPM enables high spatio-temporal resolution analysis of cardiac function

Marius Menza¹, Moritz Braig¹, Bend Jung², Daniela Föll³, Jürgen Hennig¹, and Axel Joachim Krafft¹

¹Dept. of Radiology, Medical Physics, Medical Center – University of Freiburg, Freiburg, Germany, ²Institute of Diagnostic, Interventional and Pediatric Radiology, University Hospital Bern, Bern, Switzerland, ³Cardiology and Angiology, University Heart Center, Freiburg, Germany

A detailed TPM analysis of cardiac function necessitates high spatio-temporal resolution which leads to prolonged scan durations. These scan times are typically too long for data acquisition within a single breath hold. Respiratory navigator-gating can compensate breathing-related motion, but causes an additional increase in measurement time and images with residual motion artifacts. The aim of this study was to combine UNFOLD with variable density spiral SPIRIT TPM to achieve an additional scan time reduction by a factor of 2 and an effective undersampling factor of 6. UNFOLDED SPIRIT TPM demonstrates good results and enables scan times within very short breath holding.

MOTION-RESOLVED 5D IMAGING OF THE HEART: TIME TO GET RID OF THE ECG?

Lorenzo Di Sopra¹, Davide Piccini^{1,2}, Simone Coppo³, Jessica A.M. Bastiaansen¹, Matthias Stuber^{1,4}, and Jérôme Yerly^{1,4}

¹Department of Radiology, University Hospital (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland, ²Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, Switzerland, ³Department of Radiology, Case Western Reserve University, Cleveland, OH, ⁴Center for Biomedical Imaging (CIBM), Lausanne, Switzerland

The performance of motion-resolved whole-heart MR imaging strongly depends on the quality of cardiac- and respiratory-gating signals. While navigators or self-navigation can be used to account for respiratory motion, ECG is a mainstay for synchronizing data acquisition with the cardiac cycle. We tested whether physiological motion information, directly extracted from k-space-center, can replace respiratory navigators and ECG signals. The proposed solution was applied in 9 healthy volunteers and results were compared to those obtained with the ECG-signal. Correlation between R-wave time-stamps from the ECG and the cardiac self-gating signal was excellent, while image quality and coronary artery conspicuity remained unchanged.

Computer 58

Does Right Ventricular Myocardial Kinetic Energy Correlate With Pressure Overload in Repaired Tetralogy of Fallot Patients?

Meng-Chu Chang¹, Ming-Ting Wu², Ken-Pen Weng³, Mao-Yuan Su⁴, Marius Menza⁵, Hung-Chieh Huang², and Hsu-Hsia Peng¹

¹Department of Biomedical Engineering and Environmental Sciences, National Tsing Hua University, Hsinchu, Taiwan, ²Department of Radiology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, ³Department of Pediatrics, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, ⁴Department of Medical Imaging, National Taiwan University Hospital, Taipei, Taiwan, ⁵Medical Physics, Department of Radiology, University Hospital Freiburg, Freiburg, Germany

The association of right ventricular (RV) myocardium adapted to pressure overload of repaired tetralogy of Fallot (rTOF) patient is still unclear. We evaluated three-directional myocardial kinetic energy (KE) and correlated it with RV-related pressure. The recruited rTOF patients presented decreased peak KE_{RV} both in systole and diastole. However, patient group exhibited increased percentage of radial KE_{RV} , accompanying with highly positive correlation with RV systolic pressure. In conclusion, the investigation of the correlation between myocardial kinetic energy and RV pressure overload may helpful to comprehend compensatory mechanism and myocardial remodeling in patients with rTOF.

Real-time cardiac cine based on a radial bSSFP sequence and compressed sensing: initial experience on the evaluation of left ventricular function in patients

Xiaoyong Zhang^{1,2}, Zhongzhou Chen², Xiaohai Ma³, Lei Zhao³, Hui Chen³, Caiyun Shi², Shi Su², Xin Liu², Bensheng Qiu⁴, Zhaoyang Fan⁵, and Guoxi Xie²

¹Centers for Biomedical Engineering, University of Science and Technology of China, Hefei, People's Republic of China, ²Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, People's Republic of China, ³Beijing Anzhen Hospital, Capital Medical University, Beijing, People's Republic of China, ⁴Centers for Biomedical Engineering, University of Science and Technology of China, Hefei, People's Republic of China, ⁵Cedars-Sinai Medical Center, Los Angeles, CA, United States

Cardiac cine magnetic resonance imaging is a valuable technique for assessing cardiac function. However, conventional cardiac cine imaging is based on breath-holding and ECG-triggering, which has particularly difficulty to be used for the diagnosis of the patients with arrhythmia. In this work, a novel technique for real-time cardiac cine imaging was developed and used to evaluate the left ventricular (LV) function in patients with arrhythmia. Preliminary experiment results demonstrated that the proposed method can accurately evaluate patient's LV function without the use of ECG triggering and improve the image quality of the patients with arrhythmia.

- 3154 **Computer 63** **Global circumferential strain derived from feature tracking imaging can detect early subclinical myocardial disorders in patients with heart failure preserved ejection fraction: Comparison with tagged cine magnetic resonance imaging**
 Yoshiaki Morita¹, Naoaki Yamada¹, Makoto Amaki², Yoshiaki Watanabe¹, Tatsuya Nishii¹, Atsushi Kono¹, and Tetsuya Fukuda¹

¹Department of Radiology, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan, ²Division of Cardiology, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan
- The heart failure preserved ejection fraction (HFpEF) accounts for 40–50% of all causes of heart failure. For HFpEF, identification of strain disturbances where systolic function is seemingly preserved is a decisive step toward revealing hidden heart damage. Recently, the novel technique of feature tracking imaging (FTI) was introduced for myocardial strain measurement directly from conventional cine images. We demonstrated that FTI allows for detailed strain assessment with acceptable correlation with the tagging method. In particular, global circumferential strain, which cannot be detected by analysis using cine images, may possibly serve as a sensitive and early marker of cardiac dysfunction.

- 3157 **Computer 66** **Regions of spared hypertrophy in pressure overloaded hearts promote severe systolic dysfunction as assessed by comprehensive cardiovascular magnetic resonance**
 Sebastian Maximilian Haberkorn^{1,2}, Joachim Schmitt³, Christoph Jacoby¹, Jürgen Schrader^{2,4}, Malte Kelm^{1,4}, and Uli Flögel^{2,4}

¹Department of Cardiology, University Hospital Duesseldorf, Duesseldorf, Germany, ²Department of Molecular Cardiology, Heinrich-Heine University Duesseldorf, Duesseldorf, Germany, ³Heinrich-Heine University Duesseldorf, Department of Pharmacology and Clinical Pharmacology, Duesseldorf, Germany, ⁴Cardiovascular Research Institute, Heinrich-Heine University Duesseldorf, Duesseldorf, Germany
- Regional heterogeneity of contractile function was described in patients with left ventricular (LV) hypertrophy, suggesting a predominant impairment of areas with distinct hypertrophy. Heterogeneity of myocardial hypertrophy therefore may contribute to global and regional abnormalities of LV function. Here, we systematically investigated the spatial and temporal patterning of myocardial hypertrophy in response to experimental pressure overload by cardiovascular MRI. Surprisingly, we identified a specific basolateral LV segment that is frequently spared from the development of myocardial hypertrophy and promotes systolic dysfunction. Moreover, the initial LV geometry and the vascular topology seemed to limit the extent of adaptation to pressure overload.

 Jeffery E Illman¹, James F Glockner¹, Ian C Chang², Arvin E Arani¹, Shivaram Poigai Arunachalam¹, Kiaran P McGee¹, Martha E Grogan², Angela E Dispenzieri³, and Philip A Araoz¹

¹Radiology, Mayo Clinic, Rochester, MN, United States, ²Cardiovascular Medicine, Mayo Clinic, Rochester, MN, United States, ³Department of Medicine, Division of Hematology, Mayo Clinic, Rochester, MN, United States

The association of MRI feature tracking (FT) strain with all-cause mortality was retrospectively performed on 76 patients with new diagnosis of AL amyloid. Mean follow-up was 4 years. MRI FT radial, circumferential, and longitudinal strain were each associated with all-cause mortality in univariate analysis. In separate multivariate models with serum biomarker stage, radial, circumferential, and longitudinal strain each remained prognostic. This study shows the incremental prognostic value of MRI FT strain in AL amyloidosis.

The impact of heterogeneity on regurgitation classification for pulmonary artery after repaired Tetralogy of Fallot

Pei-Hsin Wu¹, Hsiao-Wen Chung², Ming-Ting Wu³, and Cheng-Wen Ko⁴

¹Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ²Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan, ³Radiology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, ⁴Computer Science and Engineering, National Sun Yat-Sen University, Kaohsiung, Taiwan

The degree of pulmonary regurgitation has been a determinant for re-intervention for patients with repaired TOF. However, in practice, the accurate assessment of regurgitation may be interfered by the simultaneous existence of forward flow and backward flow in any single cardiac phase, which may mislead clinical decision making. In this study, we investigated the impact of heterogeneity in blood flow profiles on guiding management and the classification of regurgitation. Preliminary results suggest that pixel-wise reexamination may be required for reclassification, especially for patients with marginal/moderate regurgitant fraction value.

Feasibility Study: 2-D Self-Navigation using Compressed Sensing Reconstruction for Respiratory Gating in Free-breathing 3-D CINE Imaging

Ivo Prochaska¹, Jens Wetzi^{1,2}, Christoph Forman³, Armin Nagel⁴, and Andreas Maier^{1,2}

¹Pattern Recognition Lab, Department of Computer Science, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, ²Erlangen Graduate School in Advanced Optical Technologies (SAOT), Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, ³Siemens Healthcare GmbH, Magnetic Resonance, Erlangen, Germany, ⁴Universitätsklinikum Erlangen, Erlangen, Germany

We investigate the feasibility of using 2-D self-navigation for respiratory gating for free-breathing whole-heart 3-D CINE imaging, where respiration-induced cardiac motion may be more easily detected than in commonly used 1-D self-navigation methods. We compare self-navigation images, derived gating signals and resulting 3-D CINE images of the 1-D and 2-D methods and find that respiratory motion can be well visualized with the 2-D method; both methods show a good overlap of gating signals and little difference in resulting image quality. 2-D self-gating may thus be considered a promising alternative to 1-D self-navigation as it allows easier detection of respiratory motion.

Computer 71

Accelerated 2D Cine MRI Featuring Compressed Sensing and ECG-triggered Retro-gating

Christoph Forman¹, Randall Kroeker¹, and Michaela Schmidt¹

¹Siemens Healthcare GmbH, Erlangen, Germany

We present the combination of ECG-triggered retrospective gating and compressed sensing for segmented 2D Cine imaging at high spatiotemporal resolution. This enables capturing the complete cardiac cycle in segmented acquisitions, while significantly reducing the total acquisition time with compressed sensing and auto-calibration. The method was evaluated in 8 healthy volunteers and ventricular function parameters were compared to reference 2D Cine acquisitions featuring ECG-triggered retro-gating. Both methods resulted in comparable image quality and equivalent quantitative values for ventricular function parameters.

¹Department of Radiology, University Hospital (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland, ²Center for Biomedical Imaging (CIBM), Lausanne, Switzerland, ³Department of Pediatrics, University Hospital (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland, ⁴Department of Gynecology-Obstetrics, University Hospital (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland

The recent development of a self-gated framework to reconstruct cardiac cine MR images without the need for an external ECG signal has opened the door to prenatal cardiac examination with MRI. This study investigates the potential of this technique for fetal cardiac MRI and compares its performance with the clinical gold standard echocardiography. Standard views from clinical fetal echocardiographic examinations were acquired with both imaging modalities and two experienced readers independently compared them qualitatively and quantitatively. The results showed good agreement between the two modalities and validate the use of MRI for prenatal evaluation of the heart.

Contribution of DKI and IVIM to liver T1rho imaging in the prediction of hepatitis B virus-related liver fibrosis

shuangshuang xie¹, qing li¹, zhizheng zhuo², yu zhang², yue cheng¹, and wen shen¹

¹Tianjin First Center Hospital, Tianjin, People's Republic of China, ²Philips healthcare, Beijing, People's Republic of China

This study evaluated the individual T1rho and combined performances of T1rho, IVIM and DKI in predicting HBV related liver fibrosis. Twenty-two patients with HBV related liver fibrosis and twenty healthy control subjects were underwent whole-liver T1rho MR imaging, IVIM and DKI. The T1rho, D, D*, f, MD and MK values were compared between the two groups, and then the single and combined diagnostic efficiency of T1rho, IVIM and DKI was analyzed. Our results showed liver T1rho and MK increased and D, f, MD decreased in normal control group, and liver T1rho and MD had significantly difference between the two groups. T1rho had a moderate diagnostic efficiency, IVIM and DKI had a mild diagnostic efficiency to detect fibrosis. While, the combination of T1rho, IVIM and DKI improved the diagnostic efficiency significantly and had a good diagnostic efficiency to detect fibrosis. We conclude T1rho can be used to predicting liver fibrosis effectively, and IVIM and DKI can effectively complement existing T1rho MR imaging in predicting of liver fibrosis.

Role of diffusion-weighted imaging in distinguishing thoracoabdominal neuroblastic tumors of various histological types and differentiation grades
Yang Wen¹, Yun Peng¹, Xiaomin Duan¹, and Nan Zhang²

¹Department of Radiology, Beijing Children's Hospital, Beijing, People's Republic of China, ²Department of Pathology, Beijing Children's Hospital, Beijing, People's Republic of China

Purpose: To evaluate whether DWI allow discrimination of thoracoabdominal neuroblastic tumors of various histological types and differentiation grades. **Materials and Methods:** The DWI scans of the thoracoabdominal neuroblastic tumors in twenty-five children were retrospectively evaluated. DWI was performed with 2 b values of 0 and 800s/mm² on a 3.0T MR scanner. **Results:** In the 25 cases, ganglioneuroma (GN) was in 3 cases, ganglioneuroblastoma (GNB)-Intermixed in 4, GNB-Nodular in 3 and neuroblastoma (NB) in 15. The ADC values of the NBs were significantly lower than those of GNs/GNBs (P < .001). The ADC of GNB-Nodular/NB was significantly less than that of GN/GNB-Intermixed (p<0.0001). In GNB-Nodular and NB, the tumors with poorly differentiated and undifferentiated lesions (n=12) had significantly smaller ADC than those with differentiated composition (n=6) (P=.0012). **Conclusion:** ADC of DWI is highly valuable for discriminating thoracoabdominal neuroblastic tumors of different histological types and subtypes.

Focus or Spread? An Investigation of the Effects of b-Value Acquisition Strategies on the Stability and Bias of Prostate Diffusion Imaging Results
Xiaodong Zhong^{1,2}, Phil Young³, Peter Kollasch⁴, Venkata Chebrolu⁴, and Brian M. Dale⁵

¹MR R&D Collaborations, Siemens Healthcare, Atlanta, GA, United States, ²Department of Radiology and Imaging Sciences, Emory University, Atlanta, GA, United States, ³Department of Radiology, Mayo Clinic, Rochester, MN, United States, ⁴MR R&D Collaborations, Siemens Healthcare, Rochester, MN, United States, ⁵MR R&D Collaborations, Siemens Healthcare, Cary, NC, United States

In order to investigate the effects of b-value acquisition strategies on the stability and bias of the prostate DWI results, including calculated b-value images and ADC, a framework was developed. Using the DWI data from 8 prostate patients, this study revealed that acquiring many averages at a few b-values increases bias compared to acquiring few averages at many b-values, particularly when large numbers of averages have been removed. The framework and strategies proposed in this work may provide a useful tool to design b-value acquisition protocols to achieve the stability of prostate DWI results in clinic.

Motion Correction of Multi-b-value Diffusion-Weighted Images in the Kidney by Pyramidal Lucas-Kanade Registration

Jun Lv¹, Wenjian Huang¹, Jue Zhang^{1,2}, Xiaoying Wang^{1,3}, and Jing Fang^{1,2}

¹Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, People's Republic of China, ²College of Engineering, Peking University, Beijing, People's Republic of China, ³Department of Radiology, Peking University First Hospital, Beijing, People's Republic of China

Intravoxel incoherent motion diffusion weighted imaging (IVIM-DWI) is a novel functional MRI technique which has been demonstrated with excellent diagnostic capability. Respiratory motion artifacts are the main source of error in the acquisition and quantification of parameters for multi-b-value DWI. This work develops a reliable approach to compensate for misalignments between multi-b-value images during free-breathing based on pyramidal Lucas-Kanade registration. Preliminary results show that our proposed approach can well correct motion-related artifacts misalignment. In addition, visual quality of the ADC, f, D and D* maps indicate that contours of kidney look better defined after registration.

Intravoxel Incoherent Motion Analysis for Perfusion Using Portal Vein Embolization Pig Model

Jia Ning¹, Tilman Schubert^{2,3}, Huijun Chen¹, Chun Yuan^{1,4}, and Scott B Reeder^{3,5,6,7,8}

¹Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China, ²Clinic for Radiology and Nuclear Medicine, Basel University Hospital, Basel, Switzerland, ³Department of Radiology, University of Wisconsin-Madison, Madison, WI, United States, ⁴Department of Radiology, University of Washington, Seattle, WA, United States, ⁵Department of Medical Physics, University of Wisconsin-Madison, Madison, WI, United States, ⁶Department of Biomedical Engineering, University of Wisconsin-Madison, Madison, WI, United States, ⁷Department of Medicine, University of Wisconsin-Madison, Madison, WI, United States, ⁸Department of Emergency Medicine, University of Wisconsin-Madison, Madison, WI, United States

Portal vein embolization (PVE) is often performed before liver tumor resection, to induce hypertrophy of the anticipated liver remnant and reduce the complications after partial liver resection. The perfusion changes of the embolized and non-embolized liver segments are of great interest. Intravoxel incoherent motion (IVIM) is a component of the diffusion weighted signal model that allows for separating estimation of perfusion. Estimation of IVIM from diffusion weighted imaging which may provide a unique way to measure the perfusion of liver tissue. This study aimed to test the intra-observer repeatability of IVIM and parameters change after PVE used a pig model.

Free-breathing 3D Body Diffusion Imaging at 3T Using M1-compensated Diffusion Preparation and Stack-of-Stars Readout
Xiaoming Bi¹, Christopher Nguyen², Zhaoyang Fan², Yutaka Natsuaki¹, Rola Saouaf², Debiao Li², and Gerhard Laub¹

¹Siemens Healthcare, Los Angeles, CA, United States, ²Cedars-Sinai Medical Center, Los Angeles, CA, United States

Diffusion-weighted (DW) MRI enables qualitative and quantitative assessment of tissue diffusivity. Body diffusion imaging at 3T using conventional single-shot EPI sequence is challenged by respiratory and cardiac motions of subject, limited spatial resolution, and image distortion and ghosting. In this work, a new 3D imaging technique incorporating M1-compensated diffusion preparation and motion-robust stack-of-stars data acquisition was developed. Preliminary volunteer studies demonstrated its feasibility for free-breathing body diffusion imaging at 3T. From one patient underwent MR-PET scan, reduced ADC and increased FDG uptake was observed in the same focal lesion.

China 510080, Guangzhou, People's Republic of China, ⁷Department of Radiology, Keck School of Medicine, University of Southern California, Los Angeles, California, USA, Los Angeles, CA, United States

Intravoxel incoherent motion (IVIM) Diffusion weighted imaging (DWI) showed high clinical value in liver disease evaluation. However, it suffers from signal loss and motion artifacts due to cardiac and respiratory movement, especially in the left lobe. To improve robustness and reproducibility of parameter estimation for IVIM DWI, a novel DWI acquisition technique was introduced, which uses ECG trigger with delay time optimized by the periods of cardiac relative stationary phase. The results showed that the proposed acquisition method improves SNR of DWI data, and the repeatability and stability of IVIM-DWI derived parameters.

Intravoxel incoherent motion diffusion-weighted imaging of hepatic warm ischemia-reperfusion injury in a rabbit model

Qian Ji¹, Zhi-qiang Chu², Pan-li Zuo³, and Wen Shen¹

¹Radiology, Tianjin First Central Hospital, Tianjin, People's Republic of China, ²Transplantation, Tianjin First Central Hospital, Tianjin, People's Republic of China, ³MR Collaborations NE Asia, Siemens Healthcare, Beijing, People's Republic of China

Hepatic warm ischemia-reperfusion injury (WIRI) is clinically relevant in liver operation. We undertook this study to determine the feasibility of using IVIM for the early diagnosing and grading of hepatic WIRI. Fifty different grades of hepatic WIRI models and control rabbits were examined using a 3T clinical MR scanner, which followed by biochemical and histopathological analysis. There were significant differences of IVIM parameters between different groups. IVIM parameters corresponded well with biochemical parameters. ROC analysis showed the AUC of PF was the largest. This indicated that IVIM is a noninvasive and valuable technique for assessing and grading of hepatic WIRI.

Elucidation of Male Urethral Sphincter Complex Using Diffusion Tensor Imaging (DTI) based Fiber-Tracking

Kyoko Sakamoto¹, Mahadevan Rajasekaran¹, Valmiki Bhargava², Vadim Malis³, and Shantanu Sinha⁴

¹VA Medical Center, San Diego, CA, United States, ²VA Medical Center, ³Physics, UC San Diego, San Diego, CA, United States, ⁴Radiology, UC San Diego, San Diego, CA, United States

Urethral sphincters play an important role in urinary incontinence, a major clinical problem affecting the aging population. We elucidate the anatomy of the urethral sphincter muscles pertinent to urinary continence function using in vivo, non-invasive proton-density and diffusion tensor imaging and DTI-based fiber tracking in young adults. Muscle fiber tracking consistently revealed, perhaps for the first time, the existence of two sphincter like muscles, with one proximal near the bladder neck and the other more distal, supporting the two sphincter concept to constrict/close the urethral opening with important implications for the effect of prostatectomy on urethral closure function.

Computer 86

Prognostic value of the pretreatment apparent diffusion coefficient (ADC) for outcome prediction of chemorefractory colorectal liver metastases undergoing 90-Yttrium Radioembolization

Frederic Carsten Schmeel¹, Julian Alexander Luetkens¹, Frank Träber¹, Leonard Christopher Schmeel¹, Amir Sabet², Birgit Simon¹, Hans Heinz Schild¹, and Dariusch Reza Hadizadeh¹

¹Department of Radiology, University Hospital Bonn, Bonn, Germany, ²Department of Nuclear Medicine, University Hospital Saarland, Homburg/Saar, Germany

Imaging-based prediction of therapeutic response is highly desirable for further therapy decisions in patients with advanced malignancies. Therefore, we investigated whether pre-treatment values of the apparent diffusion coefficient (ADC) on diffusion-weighted MRI could predict the outcome of patients with liver-predominant metastatic colorectal cancer prior to 90-Yttrium microspheres radioembolization. Uni- and multivariate analyses were performed comparing various variables with potential impact on progression-free and overall survival. Our results reveal that pathologic pre-treatment ADC, alongside with established clinical parameters, is a strong and independent predictor of both progression-free and overall survival before RE treatment.

3178

Computer 87

Clinical Robustness of Accelerated and Optimized Abdominal Diffusion Weighted Imaging

Jana Taron¹, Jakob Weiss¹, Petros Martirosian², Alto Stemmer³, Konstantin Nikolaou¹, and Mike Notohamiprodjo¹

¹Department of Diagnostic and Interventional Radiology, University Hospital of Tuebingen, Tuebingen, Germany, ²Section on Experimental Radiology, Department of Diagnostic and Interventional Radiology, University Hospital of Tuebingen, Tuebingen, Germany, ³Siemens Healthcare GmbH, Erlangen, Germany

We evaluated the robustness of an accelerated and optimized diffusion-weighted sequence using the simultaneous-multislice (SMS) technique for scan time reduction and a 3D Diagonal diffusion mode to optimize image quality in clinical routine. 152 patients received clinically indicated abdominal MRI including the optimized diffusion-weighted sequence (DWI_{OPT}). A subgroup of 41 patients additionally received a standard diffusion-weighted sequence (DWI_{STD}) as reference. Qualitative and quantitative image parameters were evaluated. In the interindividual comparison, DWI_{OPT} proved equal to superior to DWI_{STD} with comparable ADC-values. In the patients receiving DWI_{OPT} only, image quality maintained substantial proving constant and stable results in a large cohort.

3179

Computer 88

Mean Kurtosis discriminates between low- and high-risk prostate cancer better than Mean diffusivity does

Maria Giovanna Di Trani^{1,2}, Alessandra Caporale^{2,3}, Marco Nezzo⁴, Roberto Miano⁵, Alessandro Mauriello⁶, Pierluigi Bove⁷, Guglielmo Manenti⁴, and Silvia Capuani⁸

¹SAIMLAL Dept., Morphogenesis and Tissue Engineering, Sapienza University of Rome, Rome, Italy, ²Physics Dept., CNR ISC UOS Roma Sapienza, Rome, Italy, ³SAIMLAL Dept., Morpho-functional Sciences, Sapienza University of Rome, Rome, Italy, ⁴Department of Diagnostic and Interventional Radiology, Molecular Imaging and Radiotherapy, PTV Foundation, "Tor Vergata" University of Rome, Rome, Italy, ⁵Urology Unit, Department of Experimental Medicine and Surgery, ⁶Anatomic Pathology, Department of Biomedicine and Prevention, PTV Foundation, "Tor Vergata" University of Rome, ⁷Urology Unit, Department of Experimental Medicine and Surgery, PTV Foundation, "Tor Vergata" University of Rome, ⁸CNR ISC UOS Roma Sapienza, Rome, Italy

This work was finalized to compare the diagnostic potential of Diffusion Tensor and Diffusion Kurtosis Imaging in discriminating between low- and high-risk prostate cancer (Pca). Maps of Mean Diffusivity (MD), apparent Kurtosis (K) and apparent diffusion coefficient (D) were obtained from DWIs of 24 patients with different tumour grade. K maps better highlight differences between periferal Pca, Pca and benign tissue. In particular K discriminates between low- and high-risk Pca with a higher statistical significance compared to that of MD. DKI can improve the accuracy of the current Pca diagnosis providing a useful tool for Pca detection and grading.

3180

Computer 89

Unbiased diffusional kurtosis measurements in the pelvis at low signal-to-noise ratio: A new approach for noise-level estimations

Olaf Dietrich¹, Martina Brandhuber¹, Moritz J. Schneider¹, Marco Armbruster¹, Melvin D'Anastasi¹, and Maximilian F. Reiser¹

¹Institute for Clinical Radiology, Ludwig-Maximilians-University Hospital Munich, Munich, Germany

The purpose of this study was to propose a robust technique for the determination of unbiased kurtosis values in body applications; for this aim, a new strategy to pixelwise estimate the noise level in DKI acquisitions is described and its feasibility for pelvic DKI is demonstrated in prostate tissue.

The "naive" evaluation (without considering the image noise) resulted in significantly biased positive kurtosis values of urine of $K=0.42$, (standard deviation: 0.06), indicating non-monoexponential signal decay caused by the influence of noise at higher b -values. This bias is almost completely removed ($K=-0.01$, 0.32) after including the pre-calculated noise-level map in the evaluation.

3181

Computer 90

Gradient First Moment Dependence of ADC in Liver Diffusion Weighting Imaging.

Kévin Moulin¹, Eric Aliotta^{1,2}, and Daniel B. Ennis^{1,2}

¹Department of Radiological Sciences, University of California, Los Angeles, CA, United States, ²Biomedical Physics IDP, University of California, Los Angeles, CA, United States

The effect of perfusion on Diffusion Weighting Imaging (DWI) and particularly the Apparent Diffusion Coefficient (ADC) at low b -value is a confounder in pathology assessment. In this study, in order to investigate the gradient first moment ($M1$) dependence of perfusion on the ADC, waveforms were generated using convex diffusion encoding (CODE) framework leading to a range of $M1$ for a given b -value. After comparing ADC calculated with different $M1$ and different b -value, we found that motion compensated waveform ($M1=0$) ensures independence of the ADC to perfusion even at low b -value, which can improve SNR.

3182

Computer 96

Diffusion and perfusion parameters extracted by bi-exponential model are markers of healthy human placenta development.

Michele Guerrieri^{1,2}, Silvia Capuani², Amanda Antonelli³, and Lucia Manganaro³

¹SAILMIL Dept., Morphogenesis & Tissue Engineering, Sapienza University of Rome, Rome, Italy, ²Physics Dept., CNR ISC UOS Roma Sapienza, Rome, Italy, ³Radiology Dept., Department of Radiology, Sapienza University of Rome, Rome, Italy

The purpose was to investigate the potential of bi-exponential model of diffusion-weighted (DW) signal decay to quantify diffusion and perfusion in healthy human placentas. The relation between diffusion and perfusion parameters with microstructural changes occurring during placenta development was also investigated. 26 pregnant women underwent DW examination. Apparent diffusion coefficient D, pseudo-perfusion fraction f and pseudo-diffusion coefficient D* were obtained in specific placental regions. The Pearson correlations between D, D*, f and clinical data (Gestational Age, Body-Mass Index and basal Glycaemia) were evaluated. D and f show to be good indicators of placenta morphological changes due to Gestational Age.

Radiologic-Pathologic Correlation and MR Analysis of Hepatocellular Adenoma Subtypes.

Daniel Kehler¹, George Yang², Christine Zwart¹, Marcela Salomao³, and Alvin Silva¹

¹Radiology, Mayo Clinic Arizona, Scottsdale, AZ, United States, ²University of Pennsylvania, PA, United States, ³Pathology, Mayo Clinic Arizona, Scottsdale, AZ, United States

Hepatocellular adenomas (HCA) present as four genetic subtypes that vary greatly in their clinical behavior and MR appearance. Inflammatory HCA has the highest propensity for hemorrhage, is characterized by hyperintense T2 signal, and displays arterial hyper-enhancement that persists on portal venous and delayed phases. HNF1-alpha mutated HCA portends a good prognosis, and is characterized by diffuse intracellular lipid. Beta-catenin HCA is less common and difficult to diagnose on imaging, though arguably the most important because of its high likelihood for malignant transformation. Unclassified HCA is not well understood in terms of imaging or clinical significance.

Computer 99

MRI Technique and Interpretation in the Evaluation of Hepatic Steatosis

Zachary Borden¹ and Scott Reeder²

¹Department of Radiology, University of Wisconsin-Madison, Madison, WI, United States, ²Department of Radiology, University of Wisconsin-Madison, WI, United States

Hepatic steatosis is a common affliction with important prognostic implications. Conventionally, liver biopsy has been required for the diagnosis of steatosis although this may result in inadequate spatial sampling and significant associated complications. The non-interventional imaging methods of ultrasound and computed tomography may be used but are limited in accuracy. MRI offers an ideal method to globally and accurately interrogate for liver fat. Multiple MRI techniques including spectroscopy, in-phase/out-phase, conventional fat suppression, complex and magnitude-based CSE-MRI methods have been used in the evaluation of hepatic steatosis. These techniques possess unique advantages and disadvantages which must be understood to optimize patient care.

Feasibility of measuring the T1 relaxation times before and after Gd-EOB-DTPA administration for characterization of liver tumors

Yoshihiko Fukukura¹, Takashi Iwanaga², Yuichi Kumagae¹, Hiroto Hakamada¹, Koji Takumi¹, Kiyohisa Kamimura¹, Masanoari Nakajo¹, Hiroshi Imai³, and Takashi Yoshiura¹

¹Radiology, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan, ²Radiological Technology, Kagoshima University Hospital, Kagoshima, Japan, ³Siemens Healthcare K.K., Tokyo, Japan

This study focused on the potential of T1 relaxation times measurement before and 20 min after Gd-EOB-DTPA administration to characterize liver tumors. T1 relaxation before Gd-EOB-DTPA administration showed the highest area under the receiver operating characteristic (ROC) curve for distinguishing hemangiomas and HCCs. T1 relaxation times 20 min after Gd-EOB-DTPA administration showed the highest the area under the ROC curve for differentiating HCCs from metastases. $\Delta R1$ was considered to be useful for differentiation between hemangiomas and metastases because of the highest the area under the ROC curve.

Computer 101

Dynamic contrast enhanced 3D T1WI at upper abdomen using combination of parallel imaging and compressed sensing on a wide-bore 3T unit: Comparison of effects with Gd-DTPA and Gd-EOB-DTPA

Motoyuki Katayama¹, Takayuki Masui¹, Kei Tsukamoto¹, Mitsuteru Tsuchiya¹, Yuki Hayashi¹, Masako Sasaki¹, Takahiro Yamada¹, Yuji Iwadata², Naoyuki Takei², Kang Wang³, Kevin King⁴, and Harumi Sakahara⁵

¹Radiology, Seirei Hamamatsu General Hospital, Hamamatsu, Japan, ²Global MR Applications and Workflow, GE Healthcare Japan, Hino, Japan, ³Global MR Applications and Workflow, GE Healthcare, Madison, WI, United States, ⁴Global MR Applications and Workflow, GE Healthcare, Waukesha, WI, United States, ⁵Radiology, Hamamatsu University School of Medicine, Hamamatsu, Japan

Consecutive four phases of dynamic contrast enhanced 3D T1WI in the upper abdomen could be obtained during one breath-hold in combined use of parallel imaging and compressed sensing at wide-bore 3T system. The imaging protocols with Gd-DTPA and Gd-EOB-DTPA provided good image quality. Although image contrasts with Gd-EOB-DTPA might be inferior to those with Gd-DTPA, patterns of time intensity curves with study with dynamic contrast of each protocol were similar to each other.

T2* measurements in liver at 1.5, 3 and 7T

E. Doran¹, S. J. Bawden¹, P. M. Glover¹, A. M. Peters¹, S. T. Francis¹, R. Bowtell¹, and P. A. Gowland¹

¹Sir Peter Mansfield Imaging Centre, School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom

Whole body 7T MRI has the potential to improve monitoring of chronic liver disease by building on advances made in parallel transmit technology. This abstract outlines the measurement of T2* in the liver at 7T and compares with measurements on the same subjects at 3 and 1.5T. Acceptable values were obtained across all field strengths and T2* maps of the liver were obtained from analysis of multi-gradient echo imaging sequences. This work forms the start of a normative 7T data set that will provide vital information for developing other 7T MR liver sequences.

Gadoxetic acid-enhanced MRI findings as a risk of multicentric recurrence of hepatocellular carcinoma after hepatectomy

Masaki Matsuda¹, Shintaro Ichikawa¹, Utaroh Motosugi¹, Masanori Matsuda², and Hiroshi Onishi¹

¹Radiology, University of Yamanashi, Chuoh-shi, Japan, ²First surgery, University of Yamanashi, Chuoh-shi, Japan

Nodules of non-hypervascular and low signal intensity during hepatobiliary phase (NLH nodules) detected by gadoxetic acid-enhanced magnetic resonance imaging (EOB-MRI), also known as hypovascular hypointense nodules, is important MR features that indicate the hepatocellular carcinoma (HCC) development in the future. The presence of NLH nodules is known as at high risk of HCC development in the liver. Hence, we hypothesized that NLH nodules can be also a risk of recurrence after surgical resection of HCCs. We evaluated the prognostic value of NLH nodules in patients with HCC. Presence of NLH nodules is at high risk of multicentric recurrence after hepatectomy.

IDEAL-IQ MR Imaging at 3 T for the Quantification of Fat: A Phantom Study

Masatoshi Hori¹, Noline F. Post^{1,2}, Hiromitsu Onishi¹, Hiroyuki Tarewaki³, Aliou A. Dia¹, Takashi Ota¹, Paul E. Sijens², and Noriyuki Tomiyama¹

¹Diagnostic and Interventional Radiology, Osaka University Graduate School of Medicine, Suita, Japan, ²University of Groningen, Groningen, Netherlands, ³Radiology, Osaka University Hospital, Suita, Japan

The purpose of this study was to evaluate the accuracy of fat quantification and the effects of iron on the measurement in IDEAL-IQ MR imaging at 3 Tesla by comparing the results of MRS using a fat-water-iron phantom. A gel phantom comprised of twenty-eight vials containing various proportions of fat and iron was constructed. Fat fraction and R_2^* value were measured by IDEAL-IQ and MRS on a 3-T scanner. This study showed that IDEAL-IQ yielded an accurate quantification of fat content with a smaller degree of error due to susceptibility effects of iron compared to MRS at 3 Tesla.

Computer 105

Accurate hepatic MRI proton density fat fraction assessment can be achieved with four regions-of-interestCheng William Hong¹, Tanya Wolfson², Ethan Z Sy¹, Alexandra Schlein¹, Soudabeh Fazeli Dehkordy¹, Adrija Mamidipalli¹, Scott B Reeder³, Rohit Loomba⁴, and Claude B Sirlin¹

¹Liver Imaging Group, Department of Radiology, University of California, San Diego, San Diego, CA, United States, ²Computational and Applied Statistics Laboratory, University of California, San Diego, San Diego, CA, United States, ³Departments of Radiology, Medical Physics, Biomedical Engineering, Medicine, and Emergency Medicine, University of Wisconsin, Madison, Madison, WI, United States, ⁴NAFLD Research Center, Division of Gastroenterology, Department of Medicine, University of California, San Diego, San Diego, CA, United States

A common approach to estimating a composite proton density fat fraction (PDFF) on MRI-PDFF maps is to draw a region-of-interest (ROI) in each of the nine Couinaud segments. This is laborious and technically challenging, however. In this secondary analysis of 398 patients, we demonstrate that 4-ROI sampling strategies that sample 2 ROIs in each hepatic lobe achieve close agreement with the 9-ROI composite. With further validation, a simple 4-ROI sampling strategy may become the new standard for measuring PDFF in clinical trials.

3197

¹Radiology, Kobe University Graduate School of Medicine, Kobe, Japan, ²Center for Endovascular Therapy, Kobe University Hospital, Kobe, Japan, ³Radiology, Kinki University Faculty of Medicine, ⁴Division of Radiology, Kobe University Hospital, Kobe, Japan, ⁵Philips Electronics Japan, ⁶Philips Healthcare, ⁷Radiology, Duke University Medical Center, Durham, NC, United States, ⁸Center for Advanced Magnetic Resonance Development, Duke University Medical Center

R2* relaxometry that is simultaneously obtained on proton density fat fraction map in gadoteric acid-enhanced MRI can quantitatively estimate liver function. PDFF sequence can potentially quantify steatosis, iron overload, and liver function simultaneously.

3198

Computer 107

Estimation of Lobar Liver Function using Gadoteric Acid-Enhanced MR Imaging: Comparison with ^{99m}Tc-GSA SPECT ImagingKeitaro Sofue^{1,2}, Masakatsu Tsurusaki³, Takamichi Murakami³, Kazuhiro Kitajima⁴, Utau Tanaka¹, Masato Yamaguchi^{1,2}, Koji Sugimoto^{1,2}, Satoru Takahashi¹, and Kazuro Sugimura¹

¹Radiology, Kobe University Graduate School of Medicine, Kobe, Japan, ²Center for Endovascular Therapy, Kobe University Hospital, ³Radiology, Kinki University Faculty of Medicine, ⁴Nuclear Medicine and PET Center, Hyogo College of Medicine

Hepatobiliary phase image on gadoteric acid-enhanced magnetic resonance (MR) imaging has been described as a way to quantify liver function and potential to estimate regional liver function. The purpose of this study was to investigate whether gadoteric acid-enhanced MR imaging can estimate lobar liver function by comparing with ^{99m}Tc-GSA SPECT imaging.

The results of this study showed that hepatic lobar function significantly differs according to the presence of biliary obstruction. Combined volumetric and functional assessment calculated by hepatobiliary phase images on gadoteric acid-enhanced MR images can estimate lobar liver function.

3199

Water-fat separated T1 mapping in the liver and correlation to hepatic fat fractionClaudia Fellner¹, Philipp Wiggermann¹, Dominik Nickel², Niklas Verloh¹, Stephan Kannengießer², Christian Stroszczyński¹, and Michael Haimerl¹

¹Institute of Radiology, University Hospital Regensburg, Regensburg, Germany, ²MR Application Predevelopment, Siemens Healthcare, Erlangen, Germany

Fat signal fraction (FF) and R2* mapping as well as MRS of the liver were performed in 201 patients. Results for FF from imaging and MRS were compared to a newly defined parameter T1_FF. T1_FF was calculated from a variable flip angle 3D GRE technique with 2 echo times. Based on the Dixon method, T1 maps from in-phase and from water signal were calculated and T1_FF was deduced. T1_FF correlated well with FF and might be used as a novel estimation of fat fraction. Relevant discrepancies were seen in cases with high R2*.

Quantitative Assessment of Liver Fibrosis using MR-Phase InformationMotohira Mio¹, Tetsuya Yoneda², Kazuki Tani¹, Tatsuo Toyofuku¹, Toshihiro Maeda¹, and Syoichi Morimoto³

¹Department of Radiology, Fukuoka University Chikushi Hospital, Fukuoka, Japan, ²Department of Medical Physics in Advanced Biomedical Sciences, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan, ³Department of Radiology, Fukuoka University Hospital, Fukuoka, Japan

The aim of this study was to evaluate a potential of MR-phase information for a quantification of liver fibrosis. We measured phase value of the liver and examined the correlation between that value and the stage of fibrosis. Additionally, we also evaluate the correlations among phase value and the serum biomarkers of fibrosis and cirrhosis. The phase value showed high statistical correlation to stages of fibrosis, and to be linearly proportional to the following biomarkers; PLT, APRI, FIB-4 index. In conclusion, MR-phase information may be to be a noninvasive quantitative tool for liver fibrosis and its progression.

3201

Weighted k-t SPIRiT with Golden Angle Radial Sampling for Dynamic Contrast-Enhanced Liver ImagingJunyu Wang^{1,2}, Fuyixue Wang², Yajie Wang², Jia Ning², Zijing Dong², Kui Ying³, and Huijun Chen²

¹Department of Biomedical Engineering, Beijing Jiaotong University, Beijing, People's Republic of China, ²Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China, ³Key Laboratory of Particle and Radiation Imaging, Ministry of Education, Medical Engineering and Institute, Department of Engineering Physics, Tsinghua University, Beijing, People's Republic of China

Acquiring high spatial-temporal resolution images is important for dynamic contrast-enhanced (DCE) imaging. In this work, we proposed a weighted k-t SPIRiT method and tested it in both simulation and in-vivo liver imaging studies based on motion-insensitive golden angle radial stack-of-stars sampling. In this study, feasibility of the weighted k-t SPIRiT has been validated. The results showed that, weighted k-t SPIRiT can improve the image quality compared with SPIRiT, while preserve highly accurate temporal information.

Assessment of early stage of liver fibrosis using MRI T1rho

Qing Li¹, Shuangshuang Xie², Zhizheng Zhuo³, Yue Cheng², and Wen Shen²

¹Tianjin First Center Hospital, Tianjin, People's Republic of China, ²Tianjin First Center Hospital, People's Republic of China, ³Philips healthcare, Beijing, People's Republic of China

This study assessed the potential of MR T1rho for early liver fibrosis. Ten normal contrast (N), twelve patients with liver fibrosis stage F1 and seven with F2 took the MR T1rho scan. With the stage of liver fibrosis raising, T1rho value increased. And T1rho value of N vs. F1, N vs. F2 and N vs. F1-2 showed significant difference. And the AUC of N vs. F1, N vs. F2 and N vs. F1-2 were 0.858, 0.810, and 0.838. We conclude that MR T1rho has potential to diagnose the early stage of liver fibrosis.

¹Department of Radiology, the Third Affiliated Hospital, Sun Yat-sen University (SYSU), Guangzhou, People's Republic of China, ²GE Healthcare MR Research China, Guangzhou, People's Republic of China, ³MR Research China, GE Healthcare, Beijing, ⁴Mayo Clinic

Hepatocellular carcinoma (HCC) is the most common primary malignancy of the liver worldwide. Microvascular invasion (MVI) is a significant predictor of prognosis and preoperative prediction of MVI is useful for deciding treatment strategy. We assessed the value of ADC and IVIM texture parameters in predicting the MVI of HBV-related HCCs by whole tumor analysis. Our results showed that ADC and IVIM derived texture parameters were useful for the prediction of MVI of HCCs. Texture analysis of ADC and IVIM is a promising method for predicting MVI of HBV-related HCC.

Liver R2 Quantification at 3 Tesla in Patients with Iron Overload - Interim Validation Result

Ali Pirasteh¹, Qing Yuan¹, Changqing Wang², Diego Hernando², Scott B Reeder³, Ivan Pedrosa⁴, and Takeshi Yokoo¹

¹Radiology, University of Texas Southwestern Medical Center, Dallas, TX, United States, ²Radiology, Medical Physics, University of Wisconsin, Madison, WI, United States, ³Radiology, Medical Physics, Biomedical Engineering, Medicine, Emergency Medicine, University of Wisconsin, Madison, WI, United States, ⁴Radiology, Advanced Imaging Research Center, University of Texas Southwestern Medical Center, TX, United States

Determination of liver iron concentration (LIC) by R2-relaxometry has been extensively validated at 1.5T but feasibility of translating this technology to 3T remains uncertain. The purpose of this study was to assess the feasibility of a R2 quantification at 3T against the standard 1.5T R2 in subjects with known or suspected iron overload. In 13 subjects enrolled thus far, we found that liver R2 at 3T linearly correlated with R2 at 1.5T over observed LIC range of 0.3-32.3 mg iron/g liver. We conclude that noninvasive liver LIC determination may be feasible by R2-relaxometry at 3T.

Assessment of magnetic resonance imaging markers in the event of drug induced liver toxicity

Abigail Kaur Cahil¹, Dan Antoine¹, Atul Minhas², Thomas Leather², Anja Kipar³, Kevin Park¹, and Harish Poptani²

¹Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, United Kingdom, ²Centre for Pre-Clinical Imaging, University of Liverpool, Liverpool, United Kingdom, ³Institute for Veterinary Pathology, University of Zurich, Zurich, Switzerland

Challenges faced in diagnosis and treatment of drug induced liver injury (DILI) have formed the aim of this project to quantify non-invasive MRI and MRS markers to aid research into future therapeutics of DILI. Using an acetaminophen overdose model, we have managed to quantify 4 different MRI biomarkers: liver volume, T2 mapping, ADC and water/fat ratio. Significant changes were observed with an increase in liver volume and T2 relaxation and water/fat ratio, with a decrease in diffusion coefficient. Some degree of normalization in T2 and ADC values was noted after NAC treatment indicating that MRI and MRS can play an important role in the diagnosis of DILI.

Using MRI to assess alterations in liver blood flow and oxygenation in response to physiological stress tests: meal challenge, hypercapnia and hyperoxia.

Eleanor F Cox^{1,2}, Naveenthan Palaniyappan², Richard Dury¹, Robert Scott², Guruprasad P Aithal², I Neil Guha², and Susan T Francis^{1,2}

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom, ²NIHR Nottingham Digestive Diseases Biomedical Research Unit, Nottingham University Hospitals Trust and the University of Nottingham, Nottingham, United Kingdom

Assessment of the capacity for dynamic changes in liver blood flow and oxygenation may provide a mechanism to improve the stratification of chronic liver injury. Here we assess dynamic hepatic blood flow and liver T_2^* alterations in response to postprandial hyperaemia following a meal, and hypercapnia and hyperoxia gas challenges. We show significant changes in blood flow and T_2^* in response to these challenges, and highlight that both the mode and FWHM of the T_2^* distribution should be assessed. However, such stress tests can only be applied in participants with higher baseline T_2^* for any change to be evident.

Variable Density CAIPIRINHA for Highly Accelerated Volumetric Dynamic Contrast-Enhanced Imaging of Liver

Fuyixue Wang^{1,2}, Zijong Dong¹, Feiyu Chen^{3,4}, Yuxin Hu^{3,4}, Jia Ning¹, Feng Huang⁵, and Huijun Chen¹

¹Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China, ²Harvard-MIT Health Sciences and Technology, MIT, Cambridge, MA, United States, ³Department of Radiology, Stanford University, Stanford, CA, United States, ⁴Department of Electrical Engineering, Stanford University, Stanford, CA, United States, ⁵Neusoft Medical System, People's Republic of China

Dynamic Contrast-Enhanced (DCE) imaging is widely used in detection and characterization of many liver diseases. In clinical practice, breath holding is commonly used to overcome respiratory motion and get high quality images. However, long breath holds can be painful or unavailable for some patients. To address this problem, we present a variable density 2D CAIPIRINHA sampling technique with a novel reconstruction framework for highly accelerated volumetric DCE liver imaging. Simulation and in-vivo experiments were performed to evaluate the performance of the proposed method compared with other current techniques. The results show great improvement of image quality within shorter acquisition time.

Factors related to the failure of MR elastography of the liver: multivariate analysis

Kengo Yoshimitsu¹

¹Radiology, Fukuoka University, Fukuoka, Japan

Seventy consecutive patients with chronic liver diseases and whose R_2^* values of the liver exceeded 100 s^{-1} were retrospectively recruited, and factors related to MR elastography failure were analyzed. Iron accumulation which corresponds to R_2^* value over 200 s^{-1} and Child-Pugh score 10 are found to be the two independently significant factors that are related to the failure of MR elastography of the liver. For the assessment of the degree of liver fibrosis in those associated with these factors, other modality, such as ultrasonic elastography, may be considered.

Computer 120

Diagnosis of Liver Cirrhosis Using Morphological Score with Magnetic Resonance Laparoscopy

Satoshi Funayama¹, Utaroh Motosugi¹, Shintaro Ichikawa¹, and Hiroshi Onishi¹

¹Department of Radiology, University of Yamanashi, Japan, Yamanashi, Japan

Liver biopsy is a gold standard for the diagnosis of liver cirrhosis. However, biopsy can be false negative because of small amount of tissue sampled. Laparoscopy has been also used as another gold standard for the diagnosis of cirrhosis by directly assessing the liver surface, which compensate for the limitation of biopsy. Laparoscopy like 3D image can be obtained by 3D reconstruction of gadoteric acid-enhanced hepatobiliary phase images (MR laparoscopy). The two MR laparoscopy findings, i.e. the rib pitting of liver surface and the sharpness of edge, showed good performance for discriminating liver cirrhosis from non-cirrhosis.

[Fast self-gated 4D flow measurements in the murine aortic arch with retrospective radial sampling](#)

Patrick Winter¹, Kristina Andelovic², Thomas Kampf^{1,3}, Peter Jakob^{1,4}, Wolfgang Bauer², and Volker Herold¹

¹Experimentelle Physik V, Universität Würzburg, Würzburg, Germany, ²Medizinische Klinik und Poliklinik I des Universitätsklinikums Würzburg, Würzburg, Germany, ³Universitätsklinikum Würzburg, Institut für Diagnostische und Interventionelle Radiologie, Würzburg, Germany, ⁴Fraunhofer IIS, Fraunhofer EZRT, Magnetresonanz- und Röntgenbildgebung (MRB), Universität Würzburg, Würzburg, Germany

A self-navigated radial 4D-PC sequence is presented for accelerated ECG-free 4D flow measurements in the murine aortic arch. Self-navigation signals were extracted from the radial DC signal and used for retrospective motion synchronization. 3D-Cines with 30 frames were reconstructed with a spatial resolution of 100 μm . The volume flow was determined at 4 2D slices extracted from the 3D dataset and the 3D flow was visualized with streamlines. The results are in good accordance with results reported for ECG-triggered measurements. The new method yields high potential for preclinical studies of hemodynamics and can also be transferred to applications in humans.

3213

Computer 50

[Fast self-navigated PC-MRI for human cardiac flow measurements using retrospective radial sampling](#)

Patrick Winter¹, Kristina Andelovic², Peter Jakob^{1,3}, Wolfgang Bauer², and Volker Herold¹

¹Experimentelle Physik V, Universität Würzburg, Würzburg, Germany, ²Medizinische Klinik und Poliklinik I des Universitätsklinikums Würzburg, Würzburg, ³Fraunhofer IIS, Fraunhofer EZRT, Magnetresonanz- und Röntgenbildgebung (MRB)

A self-navigated radial PC-MRI sequence is presented for fast ECG-free 2D-Cine measurements with 3-dimensional flow encoding. The radial DC signal was used for retrospective self-navigation. Reconstructions were performed with an iterative CG-Sense algorithm. For each flow encoding step 2D-Cines with 30 frames, respectively, and a spatial resolution of 2.34 mm were reconstructed. The time-dependent volume flow through the pulmonary artery was quantified and the blood flow through the ventricles was visualized. The proposed method does not rely on ECG signals and is immune to distortions often observed with conventional triggering. It hence yields high potential for clinical applications.

[An MRI Phantom Study to Assess the Effects of Localized Stiffness on Aortic Hemodynamics](#)

Khalil Rachid¹ and Dima Rodriguez¹

¹Laboratoire d'Imagerie par Résonance Magnétique Médicale et Multi-Modalités (IR4M), Univ. Paris-Sud, CNRS, Université Paris-Saclay, Orsay, France

Cardiovascular complications have been highly associated with arterial stiffness which results from aging and/or vascular disease. Reduced arterial elasticity, particularly at the aorta level, increases the left ventricle load. In this work, we studied the effects of localized stiffness on an aortic phantom with respect to its severity and position relative to an upstream proximal site. As expected, our results showed that the aortic hemodynamics were altered: the pulse pressure was increased, and the flow rate decreased. Moreover, the local proximal compliance was reduced as the stiffness was brought closer to the heart. However, the pulse wave velocity remained unchanged suggesting that global stiffness measuring approaches might not detect regional wall alterations

Computer 54

Interobserver reproducibility of blood flow measurements with an abdominal 4D flow MRI sequence with spiral sampling and compressed sensing
Octavia Bane¹, Steven Pet², Mathilde Wagner^{1,3}, Stefanie Hectors¹, Hadrien A Dyvorne^{1,4}, and Bachir Taouli^{1,2}

¹Translational and Molecular Imaging Institute, Icahn School of Medicine at Mount Sinai, New York, NY, United States, ²Department of Radiology, Icahn School of Medicine at Mount Sinai, New York, NY, United States, ³Radiology, Groupe Hospitalier Pitié Salpêtrière, Paris, France, ⁴Catalyzer, Guilford, CT, United States

Our study evaluated the interobserver reproducibility of flow quantification in abdominal vessels using a novel 4D flow phase-contrast (PC) MRI sequence. The effect of liver fibrosis on blood flow metrics was also examined in 20 patients. Time-averaged vessel cross-section area, through-plane velocity and volume flow measured in 14 abdominal vessels in a subset of 10 patients were found to have acceptable interobserver agreement (Cohen's kappa 0.762). A significant increase in the hepatic artery velocity and flow, splenic vein area and flow, middle hepatic vein velocity and flow, and right hepatic vein velocity was observed in patients with advanced fibrosis/cirrhosis.

3218

Computer 55

Comparison of SENSE, GRAPPA, SPIRiT and ESPIRiT for accelerated 4D flow MRI Imaging

Xiaole Wang¹, Aiqi Sun¹, Jianwen Luo¹, and Rui Li¹

¹Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China

Parallel imaging is a promising method to shorten the scanning time of 4D flow MRI. We applied SENSE, GRAPPA, SPIRiT and ESPIRiT in 4D flow imaging on six healthy volunteers and compared the accuracy of four algorithm. We found that ESPIRiT and SPIRiT showed the better velocity maps than SENSE and Grappa. The temporal fidelity of ESPIRiT can be the best among four methods, while SENSE and GRAPPA resulted in overestimates of peak flow. In conclusion, we validate the accuracy of four widely-used parallel imaging methods for the reconstruction of velocity map in 4D flow MR Imaging.

UNFOLDed Spiral SPIRiT Phase Contrast Velocity Mapping for Scan Time Reduction of Coronary Blood Flow Measurements

Axel Joachim Krafft¹, Simon Reiss¹, Jürgen Hennig¹, and Marius Menza¹

¹Radiology – Medical Physics, Medical Center – University of Freiburg, Freiburg, Germany

Coronary flow measurements can provide important information, e.g. to assess coronary stenosis, but remain challenging due to the need for high spatio-temporal resolution in the presence of heart and respiratory motion. Progress has been made by using spiral acquisitions enabling data acquisition within a breath hold. We combined spiral SPIRiT flow measurements with UNFOLD, a technique that allows for further data undersampling and scan time shortening (here by a factor of 2), to achieve coronary flow measurements with a spatio-temporal resolution of $1 \times 1 \times 8 \text{mm}^3 < 15.5 \text{msec}$. The combined UNFOLD-spiral approach was implemented into different spiral sampling patterns and evaluated in healthy volunteers.

Respiratory changes in pulmonary flow distribution in Fontan circulation using "5-D" flow MRI

David Rutkowski^{1,2}, Christopher J. François², and Alejandro Roldán-Alzate^{1,2,3}

¹Mechanical Engineering, UW Madison, Madison, WI, United States, ²Radiology, UW Madison, Madison, WI, United States, ³Biomedical Engineering, UW Madison, Madison, WI, United States

The purpose of this study was to evaluate the respiratory effects on particle trace distribution from the vena cava to the pulmonary arteries in single ventricle patients with TCPC. Six patients were imaged using PC-VIPR and a scheme that allows for double gating to the ECG and respiratory cycles, providing flow data for separate respiratory phases. Results displayed a non-equal flow distribution to the pulmonary arteries from the vena cava and a significant difference in pulmonary flow distribution between inspiration and expiration. This may indicate the importance accounting for respiratory cycle variations when interpreting clinical TCPC results.

Computer 58

Bootstrapped Estimates of Velocity Uncertainty for 4D Flow PC-MRI

Michael Loecher¹ and Daniel B. Ennis¹

¹Department of Radiological Sciences, University of California, Los Angeles, CA, United States

We implement and analyze a bootstrapping method to estimate VNR measurements with a limited number of 4D Flow acquisitions. Bootstrapped estimates were created from sets of 2 acquisitions and sets of 5 acquisitions. The VNR maps were compared to a ground truth VNR measurement generated from 50 acquisitions in a flow phantom. The method was also demonstrated *in vivo* to generate VNR maps of the carotid arteries.

Evaluate right ventricle-pulmonary artery interaction in patients with repaired tetralogy of Fallot by 4D flow-derived kinetic energy
Meng-Chu Chang¹, Ming-Ting Wu², Ken-Pen Weng³, Mao-Yuan Su⁴, Marius Menza⁵, Hung-Chieh Huang², and Hsu-Hsia Peng¹

¹National Tsing Hua University, Hsinchu, Taiwan, ²Department of Radiology, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, ³Department of Pediatrics, Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan, ⁴Department of Medical Imaging, National Taiwan University Hospital, Taipei, Taiwan, ⁵Medical Physics, Department of Radiology, University Hospital Freiburg, Freiburg, Germany

We quantified the kinetic energy (KE) of intraventricular RV flow ($KE_{RV,flow}$), PA forward flow (KE_{PA}) and PA retrograde flow ($KE_{PA,regur}$). The purpose is to establish 4D flow-derived KE-related indices for better understanding of the RV-PA interaction. We observed the interaction between RV and PA by assessing the correlation between diastolic $KE_{PA,regur}$ and late diastolic $KE_{RV,flow}$ as well as between systolic KE_{PA} and RV mean pressure. In conclusion, we verified that altered hemodynamic conditions of RV interacted with severe PR, which may lead to RV overloading pathology and adverse outcome in rTOF patients.

Energy-loss in Fontan Circulation Develops Heterogeneous Pulmonary Perfusion: Hybrid Analysis of 2D Vortex Flow Map and 4D Flow MRI
Michinobu Nagao¹, Umiko Ishizaki¹, Yumi Shiina², Kenji Fukushima¹, Yuka Matsuo¹, Tatsunori Takahashi³, Kei Inai², In-Sam Park³, Yasuhiro Goto⁴, Yamato Shimomiya⁵, Yuzo Yamasaki⁶, Ichiro Sakamoto⁷, Kenichiro Yamamura⁸, Atsushi Takemura⁹, Masami Yoneyama⁹, and Shuji Sakai¹

¹Diagnostic Imaging & Nuclear Medicine, Tokyo Women's Medical University, Tokyo, Japan, ²Clinical Reserch for ACHD, Tokyo Women's Medical University, ³Pediatric Cardiology, Tokyo Women's Medical University, ⁴Radiological service, Tokyo Women's Medical University, ⁵Clinical Application Development Marketing Division, Ziosoft Inc, ⁶Clinical Radiology, Kyushu University, ⁷Cardiovascular Medicine, Kyushu University, ⁸Pediatrics, Kyushu University, ⁹Philips Electronics Japan

Patients with Fontan-operation, single-ventricle heart frequent have systematic collaterals that increase pulmonary blood flow. The competitive flow elevates pulmonary artery pressure, a process leading to erosion of flow energy. We developed a novel post-processing of 2D cine MRI named for "vortex flow map" to evaluate the energy-loss in Fontan-circuit. Vortex flow map shows energy-loss as small magnitude of vortex flow (MVF) and reveals the relation to heterogeneous pulmonary perfusion. In total cavopulmonary conversion, 4D flow can visualize energy-loss caused by a meandering extra-cardiac conduit and the conflict flow, leading to reduce unilateral lung perfusion.

Accurate Flow MRI: the importance of velocity distribution asymmetry

Antoine Vallatos¹, Haitham F. I. Al-Mubarak¹, James M. Mullin¹, and William M. Holmes¹

¹Glasgow Experimental MRI Centre, Institute of Neuroscience and Psychology, University of Glasgow, Glasgow, United Kingdom

This work proposes a theoretical and experimental investigation into the unexplored effect of asymmetric distribution of intra-voxel velocities on the accuracy of Flow MRI. Our experimental results show that asymmetric velocity distributions can compromise the linearity of measured phase against applied gradient, leading to important velocimetry errors. A theoretical expression of the observed phase measurement errors is introduced, relating them to velocity distribution properties such as variance, skewness and kurtosis. This enables to explain previously reported velocimetry errors and propose solutions so as to increase the accuracy of velocity measurements.

Lurie Children's Hospital of Chicago, Chicago, IL, United States, ⁶Department of Pediatrics, Feinberg School of Medicine, Northwestern University

Mean and peak pressure gradients are an important measure of aortic stenosis severity. In this study, we present a novel method for measuring mean pressure gradients using 4D flow MRI. 4D flow MRI peak and mean pressure gradients were measured in 23 pediatric BAV patients and compared to Doppler echocardiography (echo). There was no significant difference between 4D flow MRI and echo in peak or mean pressure gradients. 4D flow MRI mean pressure gradients correlated better with echo than peak pressure gradients ($R^2=0.78$ vs. $R^2=0.27$), suggesting 4D flow to be better suited for measuring mean pressure gradients.

Computer 63

On Partial Fourier Acquisition in 4D Flow MRI of Mean Velocities and Turbulent Kinetic Energy

Jonas Walheim¹ and Sebastian Kozerke¹

¹ETH Zurich, Zurich, Switzerland

Scan time reduction with partial Fourier was investigated for 4D flow MRI of mean velocity and turbulent kinetic energy. It was shown analytically, that PF leads to a loss in resolution for phase images. According to experiments with in-vivo data, the precondition of slowly varying phases is not met for PF reconstructions of 4D flow MRI, making homodyne reconstruction and POCS fail. Therefore, it is concluded, that PF cannot recover missing k-space samples in 4D flow MRI and does not offer a benefit over symmetric k-space sampling with the same number of phase encodes.

Combining Phase Information from Phased Array Coils without Phase Unwrapping in Phase Contrast Imaging

Yi Wang^{1,2}, Xingxian Shou¹, Hai Luo², Xiang Zhou², Bin Wang², and Leping Zha^{1,2}

¹Alltech Medical Systems America, Solon, OH, United States, ²Alltech Medical Systems, Chengdu, People's Republic of China

In phase contrast flow quantitation, high spatial/temporal resolution and parallel imaging often entail the high density multiple phased array receive coils. To overcome ambiguities in coil signal combination introduced by motion, phase wrapping, image noise, and the unknown phase-offset among the coils, we used the k-space complex division of the same coil element signals from both flow compensated (FC) and flow encoded (FE) scans to eliminate the coil sensitivity phase associated with that coil element and then add all phase difference of each elements in complex domain to avoid phase unwrapping for a fast and accurate flow velocity mapping.

3229

Computer 66

Computational Fluid Dynamics of Pulmonary Circulation Before and After Induced Pulmonary Hypertension: 2D Flow versus 4D Flow MRI-Based Boundary Conditions

Sylvana Garcia-Rodríguez¹, James Leschke², Alejandro Roldán-Alzate^{1,3}, and Christopher J. François¹

¹Department of Radiology, University of Wisconsin - Madison, Madison, WI, United States, ²Rocky Vista University, CO, United States, ³Department of Mechanical Engineering, University of Wisconsin - Madison, Madison, WI, United States

Acute pulmonary hypertension was induced in dogs by micro embolization. RHC was performed, as well as 4D flow MRI pre and post-embolization. MRI data was used to develop a CFD model of the proximal pulmonary circulation while comparing two inlet boundary conditions: velocity definition as defined from 2D flow MRI and from 4D flow MRI, which takes into account the directionality of the velocity. WSS tended to decrease post-embolization. Pressure gradient distribution shows that during peak systole, a constant normal inlet condition might be sufficient for CFD simulation; however, differences might be present during diastole.

Flow angle (°)	0.00 - 0.00

¹Radiology, UMC Utrecht, Utrecht, Netherlands, ²Brain Center Rudolf Magnus, UMC Utrecht, Utrecht, Netherlands

7T 2D Qflow is capable of measuring blood flow velocity in the superficial perforating arteries. These arteries run through the semi oval center of the white matter in the brain and have diameters smaller than 200 μm. Due to the small diameters, partial volume effects of perforators with surrounding tissue cause velocity underestimation. With simulations and experiments we show that tilt optimized nonsaturated excitation (TONE) significantly increases SNR and decreases velocity underestimation in superficial perforating arteries.

¹Radiology, UMC Utrecht, Utrecht, Netherlands

The lenticulostriate arteries are involved in small vessel disease and their blood flow velocity and pulsatility has been measured with 7T 2D Qflow. To make this measurement more widely available we aimed to translate it to 3T by increasing blood SNR with a contrast agent. In this study we show that the 2D Qflow acquisition can measure blood flow velocity and its pulsatility in lenticulostriate arteries at 3T, even without the use of a contrast agent.

Respiratory Controlled Adaptive K-space Reordering (ReCAR) Improves 4D Flow Image Quality

Ning Jin¹, Andreas Greiser², Kelvin Chow³, Susanne Schnell⁴, Alex J Barker⁴, and Michael Markl^{4,5}

¹Siemens Healthcare, Columbus, OH, United States, ²Application Development, Siemens Healthcare, Erlangen, Germany, ³Siemens Healthcare, Chicago, IL, United States, ⁴Department of Radiology, Feinberg School of Medicine, Northwestern University, Chicago, IL, United States, ⁵Department of Biomedical Engineering, Northwestern University, Chicago, IL

4D flow normally uses respiratory gating to mitigate breathing artifacts for thoracic and abdominal applications. Respiratory Controlled Adaptive k-space Reordering (ReCAR) employs k-space reordering based on the current respiratory position. It has been reported to increase respiratory gating efficiency for 4D flow applications. The purpose of this study was to systematically compare the image quality of 4D flow data acquired with and without adaptive k-space reordering.

[The importance of correcting for through-plane heart motion in the assessment of aortic regurgitation using PC-MRI as estimated by feature tracking cine-MRI](#)

Frida Svensson^{1,2}, Alexander Johansson³, Åse Johnsson^{2,3}, and Kerstin Magdalena Lagerstrand^{1,2}

¹Dept. of Medical Physics and Techniques, Sahlgrenska University Hospital, Gothenburg, Sweden, ²Sahlgrenska University Hospital, Gothenburg, Sweden, ³Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, ³Dept of Radiology, Sahlgrenska University Hospital, Gothenburg, Sweden, Sahlgrenska University Hospital

Phase contrast measurements are prone to velocity offsets due to through-plane motion of the heart. Here we examine the impact of these velocity offsets on the assessment of aortic regurgitation using a promising method for quantification of the through-plane heart motion. Without correction for through-plane heart motion, the phase contrast measurements significantly underestimated the severity of the regurgitation and the underestimation varied highly between individuals. This calls for development of reliable and robust methods, such as the proposed tracking method, for individual correction of through-plane heart motion in the phase contrast measurements.

[Quantitative dynamic MRI in the phase domain: Characterization of coronary arterial morphology using a simple Fourier method to accurately estimate bolus arrival times in DCE-MRI perfusion imaging](#)

Karl P Kunze¹, Teresa Vitadello², Christoph Rischpler¹, Markus Schwaiger¹, and Stephan G Nekolla¹

¹Nuclear Medicine, TU Munich, Munich, Germany, ²Cardiology, TU Munich, Munich, Germany

This abstract proposes a simple method to extract the bolus arrival time (BAT) from myocardial DCE-MRI perfusion data using a low-frequency phase reconstruction of the deconvolution of arterial input functions with myocardial tissue curves. A simulation study is performed to test the proposed technique with respect to accuracy, robustness and superiority to existing approaches. A clinical PET/MRI example and a control group are examined to show the robustness of BAT estimation even without post-processing steps like surface coil intensity correction or saturation correction. The interpretation of the BAT as a surrogate for coronary path lengths is supported by coronary angiography.

[Validation of the Intravoxel Incoherent Motion Model in the Healthy Human Heart using Black-Blood Preparation](#)

Georg Spinner¹, Constantin von Deuster¹, Christian Torben Stoeck¹, and Sebastian Kozerke¹

¹Institute for Biomedical Engineering, ETH Zürich, Zürich, Switzerland

In vivo cardiac Intravoxel Incoherent Motion Imaging (IVIM) offers the potential to estimate myocardial perfusion without the need for contrast agents. The IVIM parameter estimates, however, suffer from low signal-to-noise ratio, patient motion and are depending on imaging settings as well as on diffusion gradient shapes. In the present work, further evidence is presented that estimation of perfusion using a second-order motion compensated diffusion weighted sequence in the in vivo human heart is possible.

Heart-Rate Independent T2 Mapping for Overcoming Loss of BOLD Sensitivity in Conventional Cardiac T2 MRI Acquired Under Vasodilator Stress

Hsin-Jung yang¹, Damini Dey¹, Jane Sykes², John Butler², Xiaoming Bi³, Behzad Sharif¹, Ivan Cokic¹, Sotirios Tsafaris⁴, Debiao Li¹, Piotr Slomka¹, Frank Prato², and Rohan Dharmakumar¹

¹Cedars Sinai Medical Center, Los Angeles, CA, United States, ²Lawson Health Research Institute, ³Siemens Healthcare, ⁴IMT School for Advanced Studies Lucca

Despite the advances to date, myocardial BOLD MRI continues to be plagued by imaging confounders, which limit its reliability. We hypothesized that (a) the loss in BOLD sensitivity is dependent on the magnitude of the change in heart rate (HR) between rest and vasodilator stress; and (b) HR-insensitive T2 maps can enable BOLD changes to be accurately captured. We tested our hypothesis by examining the BOLD response to a HR-insensitive T2 mapping approach and conventional T2 mapping. Our results show that reliability of T2-based myocardial BOLD MRI could be markedly improved through heart-rate-insensitive T2 acquisitions.

Spiral simultaneous multi-slice first-pass myocardial perfusion imaging

Yang Yang¹, Matthew Van Houten², Patrick Norton³, Klaus Hagspiel³, Christopher Kramer^{1,2}, John Mugler^{2,3}, and Michael Salerno^{1,2,3}

¹Medicine, University of Virginia, Charlottesville, VA, United States, ²Biomedical Engineering, University of Virginia, Charlottesville, VA, United States, ³Radiology, University of Virginia, Charlottesville, VA, United States

First-pass contrast-enhanced myocardial perfusion imaging is an important tool to assess patients with coronary artery disease, but current techniques are still limited by spatial-temporal resolution and ventricular coverage. Simultaneous multi-slice (SMS) utilizes multi-band (MB) RF pulses which can greatly improve sampling efficiency. We develop an SMS-spiral perfusion pulse sequence by modulating the phase of excitation RF pulses of multiple slices with a Hadamard matrix to achieve significant signal cancellation and an incoherent aliasing pattern. The pulse sequence is evaluated in 23 patients with MB factors of 2, 3 and 4 resulting in high image quality.

10-fold Spatial-Only Acceleration For High-Resolution Myocardial Perfusion Using Multi-Band Imaging and Multi-Band Outer Volume Suppression

Sebastian Weingartner^{1,2,3}, Steen Moeller², Chetan Shenoy⁴, and Mehmet Akçakaya^{1,2}

¹Electrical and Computer Engineering, University of Minnesota, Minneapolis, MN, United States, ²Center for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN, United States, ³Computer Assisted Clinical Medicine, Heidelberg University, Mannheim, Germany, ⁴Department of Cardiology, University of Minnesota, Minneapolis, MN, United States

Myocardial perfusion imaging is clinically established for the detection of myocardial ischemia and requires rapid imaging to monitor the uptake of a contrast-agent in the heart. Spatial resolution or coverage is commonly increased by exploiting temporal correlations, at the risk of inducing temporal blurring. Here, we investigate the use of simultaneous multi-slice imaging for high spatial-only acceleration. Outer-volume-suppression using multi-band saturation-slabs (MB-OVS) were used to facilitate high multi-band factors. Phantom results, show through signal suppression outside region-of-interest with MB-OVS. In-vivo results show robust image quality throughout the contrast uptake and washout with 9-slice LV coverage at a temporal resolution <550ms.

Estimating extraction fraction and blood flow by combining first-pass myocardial perfusion and T1 mapping results
Devavrat Likhite¹, Promporn Suksaranjit², Ganesh Adluru¹, Chris McGann², Brent Wilson², and Edward DiBella¹

¹Department of Radiology and Imaging sciences, University of Utah, Salt Lake City, UT, United States, ²Division of Cardiovascular Medicine, University of Utah, Salt Lake City, UT, United States

Dynamic contrast enhanced MRI is maturing as a tool in contemporary cardiovascular medicine. However, there are challenging areas that have not been fully understood, such as modeling extraction of the contrast agent from the vasculature to the extravascular space. We present a technique that exploits information overlap between two different cardiac MRI techniques, namely, DCE-MRI and T1 mapping, in order to estimate extraction and flow. Our study shows that extraction fraction and myocardial blood flow can be estimated by fixing extracellular volume (ECV) to values obtained from T1 mapping.

Optimized 2D radial CAIPIRINHA for cardiac perfusion MRI

Ye Tian^{1,2}, Ganesh Adluru², Jason Mendes², and Edward DiBella²

¹Physics and Astronomy, University of Utah, Salt Lake City, UT, United States, ²Radiology and Imaging Sciences, University of Utah, Salt Lake City, UT, United States

We propose an optimized offset golden angle trajectory of 3-slice radial CAIPI for more uniform distribution of phase modulated rays. Both computer simulation and phantom scan demonstrate that our proposed method has less artifact. Simulation studies show a 41% reduction in aliasing energy when compared to conventional golden angle trajectory. As well, optimization with an asymmetric echo readout resulted in a reduction of acquisition time by 15% with little sacrifice of image quality. These two methods can benefit simultaneous multi-slice perfusion acquisitions.

Analysis of Coronary Contrast Agent Transport in Bolus Based Quantitative Myocardial Perfusion MRI Measurements with Computational Fluid Dynamics (CFD) Simulations in High Performance Computing (HPC) Environments

Johannes Martens¹, Sabine Panzer¹, Jeroen van den Wijngaard², Maria Siebes², and Laura Maria Schreiber¹

¹Comprehensive Heart Failure Center, University Hospital Wuerzburg, Wuerzburg, Germany, ²Dept. of Biomedical Engineering & Physics, Academic Medical Center, Amsterdam, Netherlands

Aim of the project is the execution of computationally extremely challenging CFD simulations of blood flow and contrast agent (CA) transport in coronary arteries on HPC clusters. Therefore scalability testing is performed to assess the suitability of applied software codes in HPC environments. Cardiovascular 3D-models are extracted from high-resolution cryomicrotome imaging data and meshed with computational grids. Navier-Stokes-equations for blood flow and the advection-diffusion-equation for CA transport are solved to obtain CA bolus dispersion in the epicardial vessels. We find indications of asymptotically decreasing dispersion effects with increasing vessel generation.

BOLD Effect of Oxygen-Inhalation T2-star MRI Surrogates Systemic and Myocardial Oxygen Consumption in Heart Failure and Myocardial Infarction

Michinobu Nagao¹, Kenji Fukushima¹, Umiko Ishizaki¹, Yuka Matsuo¹, Yuzo Yamasaki², Tetsuya Matoba³, Tomomi Ide³, Atsushi Takemura⁴, Mitsuru Momose¹, and Shuji Sakai¹

¹Diagnostic Imaging & Nuclear Medicine, Tokyo Women's Medical University, Tokyo, Japan, ²Clinical Radiology, Kyushu University, ³Cardiovascular Medicine, Kyushu University, ⁴Philips Electronics Japan

Measurement of oxygen consumption (OC) has been less than satisfactory in patients with heart failure. This has necessitated the invasive techniques to measure the total oxygen demand with cardiopulmonary exercise (CPX). The present study proposes a novel method to quantify OC using BOLD effect of oxygen-inhalation T2* MRI. Difference between oxygen-T2* and room-air-T2* (ΔT_2^*) was identified as an estimate of OC. ΔT_2^* was significantly correlated with systematic and myocardial OC expressed as the results of CPX and myocardial fatty acid scintigraphy. Our method allows assessing non-invasively OC in vivo. ΔT_2^* could be used as an imaging biomarker for heart failure.

Computer 18

Myocardial Edema Imaging using Single-shot T2STIR Prepared bSSFP

Yanjie Zhu¹, Dan Yang², Yucheng Chen², Dong Liang¹, Xin Liu¹, and Yiu-Cho Chung¹

¹Paul C. Lauterbur Research Centre for Biomedical Imaging, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, People's Republic of China, ²Department of Cardiology, West China Hospital, Chengdu, People's Republic of China

STIR-TSE is useful in imaging myocardial edema. However, it is sensitivity to cardiac motion, resulting in myocardial inhomogeneity. T2p-bSSFP overcomes this issue, but averaging is commonly used to improve its contrast. We propose a novel single-shot imaging technique that generates "STIR like" contrast and improves contrast between edema and normal myocardium compared to T2p-bSSFP. The performance of the new sequence (T2STIR-bSSFP) was evaluated by phantom study and in patients with acute myocardial infarction. The results show that the average CNR of T2STIR-bSSFP between edema and myocardium was 1.9 times better than T2p-bSSFP.

Ungated free-breathing late gadolinium enhancement imaging with a radial simultaneous multi-slice acquisition

Ganesh Adluru¹, Jason Mendes¹, Brent Wilson², and Edward DiBella¹

¹Radiology and Imaging Sciences, University of Utah, Salt lake city, UT, United States, ²Cardiology, University of Utah, Salt Lake City, UT, United States

Late Gadolinium Enhancement imaging is the gold standard for identifying infarcted myocardium. Existing data acquisition methods rely on good ECG-gating signal and breathholding to acquire images in quiescent diastolic cardiac phase. However, in patients with arrhythmias and when imaging at higher field strengths, R-R interval is inconsistent and a good ECG signal can be challenging. This can lead to increased acquisition time and inconsistent recovery of longitudinal magnetization affecting signal-to-noise ratio and optimal myocardial nulling. Here we propose an ungated free-breathing scheme that acquires multiple slices at the same time with consistent nulling of healthy myocardium at systole and diastole.

Quantitative Inversion Time Prescription for Late Gadolinium Enhancement Using T1-based Synthetic Inversion Recovery Imaging – Eliminating the Subjective Estimation of Inversion Time

Akos Varga-Szemes¹, Rob J van der Geest², Carlo N De Cecco¹, Taylor M Duguay¹, U. Joseph Schoepf¹, and Pal Suranyi¹

¹Department of Radiology and Radiological Science, Medical University of South Carolina, Charleston, SC, United States, ²Department of Radiology, Leiden University Medical Center, Leiden, Netherlands

Conventional Look-Locker (LL)-based inversion time (TI) estimation prior to late gadolinium enhancement (LGE) imaging has multiple limitations, including: the long breath-hold, the collected images are in different cardiac phases, and the subjective TI estimation. In this study we aimed to develop a quantitative T1 mapping-based synthetic inversion recovery (IR_{synth}) approach allowing for the quantitative determination of the optimal TI for LGE imaging. We showed in 40 patients that the IR_{synth} method provides better quality of myocardial signal nulling, retrospective TI selection, higher TI resolution, no need for further LL correction or TI adjustment, and less operator dependence.

Validation of Contrast Enhanced Cine Steady-State Free Precession and T2-Weighted CMR for Assessment of Ischemic Myocardial Area-At-Risk

Esben Søvsø Szocska Hansen^{1,2}, Steen Fjord Pedersen³, Steen Bønløkke Pedersen⁴, Hans Erik Stilling Bøtke⁵, and Won Yong Kim⁵

¹The MR Research Centre, Aarhus University, 8200, Denmark, ²Danish Diabetes Academy, Odense, Denmark, ³Department of Cardiothoracic and Vascular Surgery T, Aarhus University Hospital, 8200, Denmark, ⁴Department of Endocrinology and Internal Medicine, Aarhus University Hospital THG, Denmark, ⁵Department of Cardiology, Aarhus University Hospital, 8200, Denmark

Measuring myocardial salvage is important to evaluate the possible cardioprotective effects of adjunctive cardioprotective intervention in patients with myocardial infarction undergoing primary percutaneous intervention. Contrast-enhanced steady-state free precession magnetic resonance imaging (CE-CINE) has recently been used to quantify AAR and validated against myocardial perfusion SPECT. In this study we sought to determine how well T2-STIR and CE-CINE depicts AAR in an experimental porcine model of myocardial ischemia-reperfusion injury using histopathology as the reference for infarct size and AAR.

Computer 23

Effects of a Gadolinium Based Contrast Agent on the Myocardial R2* Relaxation Rate in Patients with Chronic Myocardial Infarction

James W Goldfarb¹, Nathaniel Reichel¹, Jie J Cao¹, and Dana C Peters²

¹St Francis Hospital, Roslyn, NY, United States, ²Yale University, New Haven, CT, United States

In this proof-of-concept study, we studied the effects of a contrast agent on R2*/T2* relaxation in dense myocardial fibrosis. A significant change in myocardial R2* was found after contrast and an R2* difference existed after contrast agent administration between fibrosis and remote myocardium. On average, viable myocardial R2* increased by 4.5 Hz while infarcted increased by 9.3 Hz at 1.5T with a clinical contrast agent.

QISS FISS (Quiescent-Interval Slice-Selective Fast Interrupted Steady-State): A Best-of-Both-Worlds Solution to Nonenhanced MR Angiography at 3 Tesla

Robert R. Edelman^{1,2}, Shivraman Giri³, and Ioannis Koktzoglou^{4,5}

¹Radiology, NorthShore University HealthSystem, Evanston, IL, United States, ²Radiology, Northwestern University, Chicago, IL, United States, ³Siemens HealthCare, ⁴Radiology, NorthShore University HealthSystem, ⁵Radiology, University of Chicago

QISS is a robust method for nonenhanced MRA that conventionally uses a TrueFISP readout. At 3 Tesla, use of TrueFISP is challenging due to high RF power deposition and sensitivity to off-resonance artifacts. In order to overcome these limitations, we implemented a QISS technique that incorporates a new type of readout that is a hybrid of TrueFISP and FLASH pulse sequences, which we call "Fast Interrupted Steady-State" (FISS). A pilot study was conducted to evaluate the potential benefits of QISS FISS at 3 Tesla for evaluation of the peripheral arteries and great vessels of the chest.

Characterizing the Cardiac Phase Dependence of Motion Compensated CODE cDTI

Eric Aliotta^{1,2}, Kevin Moulin¹, Patrick Magrath^{1,3}, and Daniel B. Ennis^{1,2,3}

¹Department of Radiological Sciences, University of California, Los Angeles, CA, United States, ²Biomedical Physics IDP, University of California, Los Angeles, CA, United States, ³Department of Bioengineering, University of California, Los Angeles, CA, United States

First and second order motion compensated convex optimized diffusion encoding (CODE-M₁M₂) enables robust, high resolution cardiac diffusion tensor imaging (cDTI). However, timing of the diffusion encoding relative to the cardiac cycle still requires careful evaluation to achieve precise and accurate measurements. In this study, CODE-M₁M₂ cDTI was acquired in healthy volunteers at both mid-systole and diastole to identify differences in fiber orientation, fiber cone of uncertainty (CoU), mean diffusivity (MD) and fractional anisotropy (FA). While fiber orientations were equivalent, lower CoU, lower MD, and higher FA were observed in mid-systole than in diastasis indicating improved performance.

Insights from comprehensive fetal cardiovascular MRI assessment using 3D motion-correction and metric-optimised gated phase contrast in cases of suspected coarctation of the aorta

David F A Lloyd^{1,2}, Joshua F P van Amerom¹, Maria Murgasova¹, Bernard Kainz³, Kuberan Pushparajah², John Simpson², Mary Rutherford¹, Jo V Hajnal¹, and Reza Razavi^{1,2}

¹Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, ²Department of Paediatric and Fetal Cardiology, Evelina London Children's Hospital, London, United Kingdom, ³Department of Computing (BioMedIA), Imperial College London

The antenatal diagnosis of coarctation of the aorta can be life saving; however, it is notoriously difficult to predict using ultrasound alone. We present 16 fetal cases with suspected coarctation of the aorta between 30-36 weeks, assessed using a combination of novel prenatal MRI techniques: three-dimensional motion corrected slice-volume registration and metric-optimised gated phase contrast flow measurements. Detailed 3D analysis revealed significant correlation between the size and position of the aortic isthmus and the need for neonatal surgical repair. Retrograde flow at the aortic isthmus and the angle of its insertion relative to the arterial duct may also be important variables. The comprehensive physiological data generated by combining novel fetal MRI techniques may offer powerful insights into traditionally challenging antenatal diagnoses.

Computer 28

Contact-free Cardiac Motion Estimation using the Scatter of a Parallel Transmit Coil at 7T MRI

Sven H.F. Jaeschke¹, Caitlin O'Brien², Aaron T. Hess¹, and Matthew D. Robson¹

¹Oxford Centre for Clinical Magnetic Resonance Research, University of Oxford, Oxford, United Kingdom, ²Oxford Centre for Functional MRI of the Brain, University of Oxford, United Kingdom

Cardiovascular MRI at ultra-high field strength is a growing field of research and as such there is a need for reliable, accurate, and user-independent triggering and gating. We propose a novel approach that uses directional couplers from the SAR monitoring system and an 8-channel pTx coil to measure the reflection coefficients simultaneously to determine cardiac motion with an independent component analysis and Gaussian shaped RF-monitoring pulses. This approach has the potential to improve cardiac imaging at ultra-high field CMR by providing robust triggering in periods of breath-hold and free-breathing, additional gating information and an optimised workflow with no additional set-up.

Fetal cardiac volume reconstruction from motion-corrected multi-slice dynamic MRI

Joshua FP van Amerom¹, David A Lloyd¹, Maria Kuklisova Murgasova¹, Anthony N Price¹, Shaihan J Malik¹, Paul Aljabar², Joanna M Allsop², Ana Gomes², Mary A Rutherford^{1,2}, Kuberan Pushparajah^{1,3}, Reza Razavi^{1,3}, and Joseph V Hajnal¹

¹Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, ²Centre for the Developing Brain, King's College London, London, United Kingdom, ³Department of Congenital Heart Disease, King's College London Evelina London Children's Hospital, London, United Kingdom

Motion is a significant challenge in fetal cardiac MRI. Multi-slice 2D dynamic MR data was used to reconstruct high-temporal resolution real-time images to be combined in time as 2D cine images and then in space as volumes with full coverage of the heart. Retrospective, image-based post-processing (motion correction, outlier rejection) was used to improve image quality in the presence of intra- and inter-slice motion. Reconstructed multi-slice cine images depict the complex anatomy of the fetal heart across the cardiac cycle and preliminary volume reconstructions allow multiple views to be visualised.

Computer 30

Time-Resolved Contrast-Enhanced MR Angiography with Single-Echo Dixon Background Suppression

Eric G. Stinson¹, Joshua D. Trzasko¹, Norbert G. Campeau¹, John Huston III¹, Phillip M. Young¹, and Stephen J. Riederer¹

¹Radiology, Mayo Clinic, Rochester, MN, United States

Contrast-enhanced MR angiography (CE-MRA) typically relies on a time-subtraction technique to suppress the background signal and emphasize the contrast-enhanced blood signal. However, Dixon-based background suppression has been reported to reduce motion sensitivity and improve signal-to-noise ratio in CE-MRA studies. Dual-echo Dixon techniques suffer a time penalty from acquiring an image at a second echo time, but single-echo Dixon techniques require an image at only one echo time and can reduce the time penalty. Here, time-resolved 3D single-echo Dixon CE-MRA at 3.0T with image update times of under 5 seconds is reported with results in the calves, hands, and brain.

Tomoelastography of the abdominal aorta and inferior vena cava in different hydration states

Thomas Elgeti¹, Jing Guo¹, Heiko Tzschätzsch¹, Florian Dittmann¹, Eric Barnhill¹, Jürgen Braun¹, and Ingolf Sack¹

¹Charité - Universitätsmedizin Berlin, Berlin, Germany

Tomoelastography was recently introduced for high-resolution stiffness mapping in abdominal organs. The method is based on multifrequency MR elastography and noise-robust reconstruction of shear wave speed maps. This study demonstrates the feasibility of tomoelastography for measurement of the mechanical properties of the abdominal aorta (AA) and inferior vena cava (IVC) in healthy volunteers. AA was measured stiffer than IVC with increasing disparity after drinking one liter of water. Our results demonstrate the sensitivity of MRE-measured effective stiffness values in AA and IVC to physiological alteration of the hydration state and offer a new perspective for MRE of abdominal vessels.

3267

Computer 33

Contact-free diaphragm navigation using the scatter of a parallel transmit coil at 7T

Aaron Timothy Hess¹ and Matthew D Robson¹

¹Oxford Centre for Clinical Magnetic Resonance Research (OCMR), University of Oxford, Oxford, United Kingdom

A method is presented to measure respiratory motion in mm units based on the scatter of a parallel transmit coil. The respiratory changes in scatter are observed by the local SAR monitor and converted into a respiratory measure through a calibration phase. The newly described measure was compared to the diaphragm position measured in MR images. The standard deviation of the difference between the two was 1.1 ± 0.4 mm across six volunteers. The method was implemented into a free breathing cardiac cine which showed no respiratory artefact when used to gate.

Computer 34

Interleaved ³¹P-MR spectroscopy and cine ¹H-MR imaging of the human heart at 3 Tesla

Madeleine Daemen^{1,2}, Aart J. Nederveen¹, Jeroen A.L. Jeneson^{1,3}, Gustav J. Strijkers⁴, and Adrianus J. Bakermans¹

¹Department of Radiology, Academic Medical Center, Amsterdam, Netherlands, ²Biomedical NMR, Department of Biomedical Engineering, Eindhoven University of Technology, Eindhoven, Netherlands, ³Neuroimaging Center, University Medical Center Groningen, Groningen, Netherlands, ⁴Department of Biomedical Engineering and Physics, Academic Medical Center, Amsterdam, Netherlands

Changes in the myocardial energy homeostasis have been linked to decreases in cardiac pumping performance. Current MR practice requires two consecutive recordings of ³¹P-MRS and ¹H-MRI to assess both aspects of heart physiology, with consequently long scan times, considerable patient burden, and potentially a mismatch between data from separate sessions. By efficiently interleaving 3D ISIS acquisitions for localized ³¹P-MRS with short-axis cine ¹H-MR imaging, both myocardial energy status as well as left-ventricular ejection fraction could be quantified from MR data that were acquired essentially simultaneously.

Computational modeling of arterial wall strain in a rabbit model of atherosclerosis using an elastin-specific MR contrast agent

Andrew Comerford¹, Rene Botnar¹, and Alkystis Phinikaridou¹

¹Imaging Sciences & Biomedical Engineering, King's College London, London, United Kingdom

Vulnerable plaque rupture is a major cause of common clinical events such as heart attacks and strokes. Plaques form in the arterial wall due to atherosclerosis, however not all plaques that do develop are at risk from rupture. Risk stratification is a major clinical need. This study combines elastin-specific MR contrast agent and CINE MR data from a rabbit model of atherosclerosis with finite element modeling. This combination allows the biomechanics of the arterial wall to be compared with morphological and biological indicators. Wall strains were shown to vary depending on the wall thickness and elastin content.

Dynamic PET/MR Imaging of Glucose Utilization and Contractile Function Under Hypoxic Stress

Gregory Barton¹, Kara Goss², Niti Aggarwal³, Marlowe Eldridge¹, and Alan McMillan⁴

¹Department of Pediatrics, University of Wisconsin-Madison, Madison, WI, United States, ²Department of Medicine, University of Wisconsin-Madison, Madison, WI, United States, ³Departments of Medicine & Radiology, University of Wisconsin-Madison, Madison, WI, United States, ⁴Department of Radiology, University of Wisconsin-Madison, Madison, WI, United States

The purpose of this study was to establish a methodology that could be used to study the dynamic relationship between cardiac contractile function and metabolism in a serial rest-stress model using dynamic cardiac PET/MR. To assess dynamic changes in cardiac glucose metabolism we evaluated the use of a continuous infusion of ¹⁸F-FDG. We found that increases in cardiac contractility were coupled with an increase in glucose utilization in the myocardium under hypoxic stress conditions. These results demonstrate the feasibility of performing simultaneous measures of contractile function and metabolism in the heart.

3271

Computer 37

Statistical paradigm for composite MR Angiography generated from multi-contrast MRI

Dahan Kim^{1,2}, Patrick Turski^{2,3}, Oliver Wieben^{2,3,4}, and Kevin M Johnson^{2,3}

¹Department of Physics, University of Wisconsin - Madison, Madison, WI, United States, ²Department of Medical Physics, University of Wisconsin - Madison, Madison, WI, United States, ³Department of Radiology, University of Wisconsin - Madison, Madison, WI, United States, ⁴Department of Biomedical Engineering, University of Wisconsin - Madison, Madison, WI, United States

We present an innovative paradigm to overcome artifacts of individual MR angiography techniques by utilizing complimentary information existing across multi-contrast MR images. This technique applies Bayesian statistics to extract vessel likelihoods from each image type and generates a single 'composite' angiogram. Composite angiograms are computed utilizing black blood (BB), contrast enhanced MRA (CE-MRA), and phase contrast MRA (PC-MRA) images acquired in subjects with known neurovascular disease. The composite angiogram is demonstrated to improve vessel lumen depiction overcoming artifacts in individual source images from background enhancement, air cavities, and flow in CE-MRA, BB, and PC-MRA, respectively.

The impact of kinetic isotope effects in using deuterated glucose for metabolic experiments

Alexander Funk¹, Brian Anderson¹, Xiaodong Wen¹, Chalermchai Khemthong¹, Dean Sherry^{1,2}, and Craig Malloy¹

¹Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, TX, United States, ²University of Texas at Dallas

Deuteration of ¹³C-enriched glucose has been used to prolong T₁ of hyperpolarized ¹³C with the objective of monitoring glucose metabolism to lactate. However, the effect of deuteration on the flux in glycolysis in vivo has not been investigated extensively. Deuterated glucose was studied in perfused hearts and extracts were analyzed for a deuterium kinetic isotope effect using ¹H, ¹³C and ²H NMR spectroscopy. Unexpectedly, there was extensive exchange of methyl deuterons in lactate with aqueous medium. Perdeuteration slows metabolism of glucose to lactate.

Improving Shear Wave Signal-to-Noise Ratio in 3D High Frequency Cardiac Magnetic Resonance Elastography with Subjects in Prone Position

Shivaram Poigai Arunachalam¹, Arvin Arani¹, Ian Chang², Yi Sui¹, Phillip Rossman¹, Kevin Glaser¹, Joshua Trzasko¹, Kiaran McGee¹, Armando Manduca³, Richard Ehman¹, and Philip Araoz¹

¹Radiology, Mayo Clinic, Rochester, MN, United States, ²Cardiovascular Diseases, Mayo Clinic, Rochester, MN, United States, ³Biomedical Engineering and Physiology, Mayo Clinic, Rochester, MN, United States

Myocardial stiffness is a novel biomarker for diagnosing a variety of cardiac diseases. Our recent work demonstrated the feasibility of measuring in-vivo myocardial stiffness using 3D high frequency cardiac MR elastography (MRE) in normal volunteers using octahedral signal-to-noise ratio (OSS-SNR) as a shear wave quality metric. The purpose of this work is to determine whether scanning subjects in prone position can improve the OSS-SNR compared to supine position. 47 healthy volunteers were enrolled and OSS-SNR in prone position (mean: 1.98) was significantly higher ($p < 0.01$) than the OSS-SNR in supine position (mean: 1.52) with comparable mean stiffness.

Feasibility of Cardiac bSSFP Cine MRI at 0.35T: A Comparison with 1.5T

Shams Rashid¹, Fei Han², Yu Gao², Yingli Yang³, and Peng Hu^{2,4}

¹Radiological Sciences, UCLA, Los Angeles, CA, United States, ²Radiological Sciences, University of California, Los Angeles, Los Angeles, CA, United States, ³Radiation Oncology, University of California, Los Angeles, Los Angeles, CA, United States, ⁴Biomedical Physics Graduate Program, University of California, Los Angeles, Los Angeles, CA, United States

In this study, we demonstrate the feasibility of cardiac cine MRI at 0.35T using bSSFP and compared the results with bSSFP at 1.5T.

3276

Computer 42

Cardiac Cine MRI with bSSFP-EPI at 0.35T

Shams Rashid¹, Fei Han¹, Yu Gao¹, Yingli Yang², and Peng Hu^{1,3}

¹Radiological Sciences, University of California, Los Angeles, Los Angeles, CA, United States, ²Radiation Oncology, University of California, Los Angeles, Los Angeles, CA, United States, ³Biomedical Physics Graduate Program, University of California, Los Angeles, Los Angeles, CA, United States

We have developed a bSSFP-EPI cine sequence and implemented it on a 0.35T MR system. The bSSFP-EPI cine sequence has reduced acquisition duration compared to conventional bSSFP cine.

3277

Computer 43

Optimized 2D-PACE for aorta blood flow gating and its application in T1W morphological cMRI

Fang Dong¹, Kun Zhou¹, and Shi Cheng¹

¹Siemens Shenzhen Magnetic Resonance Ltd., ShenZhen, People's Republic of China

Electrocardiogram gating is commonly used in clinical cardiac MRI. However, it takes time to attach ECG electrodes and gating signals can be easily affected. In this abstract, the 2D-PACE technique is optimized for blood flow monitoring to explore its potential as an alternative to ECG gating. A new protocol triggered by 2D-PACE for T1W cardiac morphology was also proposed. Our results showed that the optimized 2D-PACE was robust for blood flow peak detection. And combining with our new protocol, it provided comparable image quality to those from ECG gated conventional protocol, which showed a great potential for cardiac triggering.

3278

Post-Contrast Black-blood HASTE: Initial Results with Ferumoxytol

Takegawa Yoshida^{1,2}, Eun-ah Park^{1,2}, Peng Hu^{1,2}, Kim-Lien Nguyen^{1,3}, and J. Paul Finn^{1,2}

¹Diagnostic Cardiovascular Imaging Laboratory, David Geffen School of Medicine at UCLA, Los Angeles, CA, United States, ²Department of Radiological Sciences, David Geffen School of Medicine at UCLA, ³Division of Cardiology, David Geffen School of Medicine at UCLA and VA Greater Los Angeles Healthcare System

Black blood imaging is helpful in cardiovascular evaluation, but is challenging due to its dependence on through-plane blood flow. We explored ferumoxytol-enhanced black-blood Half-Fourier Acquisition Single-shot Turbo Spin-echo (HASTE) imaging for cardiovascular morphologic evaluation and compared its effectiveness with pre-contrast double inversion (DIR) HASTE. Post-ferumoxytol HASTE showed complete and homogeneous blood suppression and better qualitative image scores (all, $p < 0.001$) for all cardiovascular regions. The technique holds promise for confident definition of thrombus or plaque, independently of blood flow.

3279

Computer 46

Ferumoxytol Enhanced Cardiac Cine MRI in Patients with Implanted Cardiac Devices

Kim-Lien Nguyen^{1,2}, Takegawa Yoshida^{1,3}, Peng Hu^{1,3}, and J. Paul Finn^{1,3}

¹Diagnostic Cardiovascular Imaging Laboratory, David Geffen School of Medicine at UCLA, Los Angeles, CA, United States, ²Division of Cardiology, David Geffen School of Medicine at UCLA and VA Greater Los Angeles Healthcare System, ³Department of Radiological Sciences, David Geffen School of Medicine at UCLA, Los Angeles, CA, United States

With an aging population, more patients are receiving implantable cardiac devices (ICDs) annually. Many will need one or more cardiac MRI exams over the course of their lifetime. ICDs can cause artifacts and obscure evaluation of intra-cardiac morphology. While researchers have dealt with artifacts during late gadolinium enhancement imaging by using wideband inversion recovery, off resonance artifacts preclude reliable SSFP cine and SGE cine is degraded by blood saturation. We explored the use of ferumoxytol to mitigate device-related artifacts and flow limiting artifacts during cine MRI in patients with ICDs.

Vascular Access Mapping with Ferumoxytol MRA for TAVR Planning in Patients with Renal Impairment: A Step Closer Towards Patient-Specific Care

Kim-Lien Nguyen^{1,2}, Takegawa Yoshida^{1,3}, Adam N Plotnick^{1,3}, John M Moriarty^{1,3}, Peng Hu^{1,3}, and J. Paul Finn^{1,3}

¹Diagnostic Cardiovascular Imaging Laboratory, David Geffen School of Medicine at UCLA, Los Angeles, CA, United States, ²Division of Cardiology, David Geffen School of Medicine at UCLA and VA Greater Los Angeles Healthcare System, ³Department of Radiological Sciences, David Geffen School of Medicine at UCLA

Transcatheter aortic valve replacement (TAVR) has transformed the treatment of critical aortic stenosis, particularly for those patients whose surgical operative risks are high. However, pre-TAVR vascular mapping with CT requires 40-120 mls of iodinated contrast, which in older patients with renal impairment increases the risk of acute renal injury that portends poor prognosis. We demonstrated that ferumoxytol MRA can provide reliable vascular mapping in patients with renal impairment undergoing TAVR evaluation, without exposure to iodinated or gadolinium contrast agents.

Transpedal MR-lymphangiography - A new imaging tool for pre-interventional planning of lymphatic interventions in patients with chylous effusions

Claus Christian Pieper¹ and Hans Heinz Schild¹

¹Radiology, University Hospital Bonn, Bonn, Germany

Lymphatic interventions are increasingly performed for the treatment of chylous leakages. Pre-interventional evaluation of the central lymphatic system is important for adequate patient selection and planning of the interventional technique. We describe a new transpedal approach for MR-lymphangiography (tMRL) to evaluate the anatomy of central lymphatics including anatomical variations, as well as for detection of leakages and analysis of a potential interventional access site. Our results demonstrate that central lymphatic anatomy can be readily evaluated using tMRL in the majority of patients scheduled for lymphatic interventions. It is a well-tolerated, valuable diagnostic tool in the pre-interventional work-up of lymphatic interventions.

Impact of temporal resolution on quantitative renal perfusion MRI: Assessment using a single contrast injection and a continuous golden-angle radial sampling technique with iterative reconstruction.

Johannes Budjan¹, Philipp Riffel², Melissa M Ong², Robert Grimm³, Kai Tobias Block⁴, Frank G Zöllner⁵, Stefan O Schoenberg², Ulrike I Attenberger², and Daniel Hausmann²

¹Department of Clinical Radiology and Nuclear Medicine, University Medical Center Mannheim, Medical Faculty Mannheim, Mannheim, Germany, ²Department of Clinical Radiology and Nuclear Medicine, University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, ³Siemens Healthcare GmbH, Erlangen, Germany, ⁴Center for Advanced Imaging Innovation and Research (CAI2R), Department of Radiology, New York University School of Medicine, New York, NY, United States, ⁵Computer Assisted Clinical Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany

To evaluate the impact of temporal resolution on quantitative renal perfusion MRI, an intra-individual comparison of retrospectively reconstructed datasets with 4 different temporal resolutions (1.5s to 10.1s) was performed in 22 patients. This was achieved using a continuously acquired sequence that uses a combination of radial sampling, sparse imaging, iterative reconstruction, parallel imaging, and a single contrast injection. No statistically significant differences in renal plasma flow were found between the groups. This suggests that the effect of temporal resolution plays a subordinated role in quantitative renal perfusion MRI.

Optimization of inversion-time sampling for precise estimation of renal perfusion with ASL

Christopher C. Conlin¹ and Jeff L. Zhang¹

¹Department of Radiology and Imaging Sciences, University of Utah, Salt Lake City, UT, United States

This study outlines an approach for selecting optimal TIs at which to sample renal ASL data. We present an error-propagation factor for a model of the ASL signal and propose to optimize TI sampling through minimization of this factor. Using FAIR ASL data from 7 human subjects, we show that renal perfusion estimates obtained with optimal TI sampling are more accurate and precise than estimates obtained with uniform TI sampling, particularly when ASL data is acquired at only a few TIs.

3285

Computer 75

MR renography shows that serum-clearance methods overestimate GFR in patients with ascites

Christopher C. Conlin¹, Jeff L. Zhang¹, Kristi Carlston¹, Daniel Kim², Kathryn A. Morton¹, and Vivian S. Lee¹

¹Department of Radiology and Imaging Sciences, University of Utah, Salt Lake City, UT, United States, ²Department of Radiology, Northwestern University, Chicago, IL, United States

In this study, the impact of ascites on clearance-based GFR estimation was examined by comparing GFR estimates from ^{99m}Tc-DTPA clearance and MR renography in cirrhosis patients with varying degrees of ascites. ^{99m}Tc-DTPA clearance significantly overestimated GFR relative to MR renography in patients with moderate-to-severe ascites, likely because of extra-renal clearance of tracer into abdominal ascites fluid. Conversely, MR renography was unaffected by the presence of ascites because it tracked uptake and excretion of tracer specifically by the kidneys. This ascites-insensitivity makes MR renography a promising technique for GFR assessment in cirrhosis patients, a population with a high incidence of ascites.

3286

Computer 76

Influence of hip position on oxygenation and perfusion of renal allografts using BOLD, DWI and ASL MRI

Maryam Seif^{1,2}, Laila Mani³, Florence Nikles¹, Chris Boesch¹, Gaëlle Diserens¹, Bruno Vogt³, and Peter Vermathen¹

¹Depts. Radiology and Clinical Research, University Bern, Bern, Switzerland, ²Spinal cord injury Center, Balgrist University Hospital, University of Zurich, Zurich, Switzerland, ³Dept. Nephrology, Hypertension and Clinical Pharmacology, Hospital University of Bern, Bern, Switzerland

Functional kinking due to tethering of iliac arteries by adjacent fibrotic tissue may occur in kidney graft recipients when sitting, and in turn lead to repetitive graft hypoperfusion. The aim was to investigate if perfusion and oxygenation were changed in transplanted kidneys during leg flexion (>90°) compared to the straight-leg position by employing fMRI (DWI, BOLD, ASL). Contradicting our hypothesis, perfusion increased in flexed leg compared to straight-leg position. Furthermore, furosemide had a significantly lower impact on R2*-values in flexed than in straight leg position. In conclusion, results demonstrated an acute impact of strong leg flexion on functional renal parameters.

Reproducibility of Multiparametric Assessment of Chronic Kidney Disease

Charlotte Elizabeth Buchanan¹, Huda Mahmoud², Eleanor F Cox¹, Benjamin Prestwich¹, Nicholas M Selby², Maarten W Taal², and Susan T Francis¹

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom, ²Centre for Kidney Research and Innovation, University of Nottingham, Nottingham, United Kingdom

Chronic kidney disease (CKD) is a heterogeneous disease, with previous studies showing conflicting changes in MR parameters. Here, we use multi-parametric MRI of DWI, T₁ and T₂* mapping and ASL to assess haemodynamic and structural changes in Stage 3 and 4 CKD patients and examine the reproducibility of these measures. A significant reduction in renal cortex ADC and perfusion was found between CKD patients and healthy volunteers. In contrast, renal cortex and medulla T₁ values increased in CKD, with a reduction in corticomedullary differentiation. MR measures in CKD patients were found to be highly reproducible between scan sessions.

Multiparametric Assessment of Acute Kidney Injury

Charlotte Elizabeth Buchanan¹, Huda Mahmoud², Eleanor F Cox¹, Benjamin Prestwich¹, Maarten W Taal², Nicholas M Selby², and Susan T Francis¹

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom, ²Centre for Kidney Research and Innovation, University of Nottingham, Nottingham, United Kingdom

Acute Kidney Injury (AKI) is a sudden reduction in kidney function, with causes and degree of renal recovery varying widely between individuals. MRI provides a method to assess changes associated with AKI. Here, we use multi-parametric MRI to monitor renal changes in AKI at time of injury and recovery. At peak AKI an increase was seen in renal volumes and T₂* values while cortical ADC and perfusion was lower during the AKI phase. T₁ maps showed an increase at time of AKI with a reduction in corticomedullary differentiation. At 3 months post AKI, T₁ remained higher than HVs.

Reliable estimation of kidney filtration rate with DCE-MRI using motion-robust high spatiotemporal resolution Radial VIBE

Sila Kurugol¹, Onur Afacan², Deborah R Stein³, Michael A Ferguson³, Richard S Lee⁴, Reid Nichols², Ravi T Seethamraju⁵, Jeanne S Chow², and Simon K Warfield⁶

¹Radiology, Boston Children's Hospital and Harvard Medical School, Boston, MA, United States, ²Radiology, Boston Children's Hospital and Harvard Medical School, Boston, MA, United States, ³Pediatrics, Boston Children's Hospital and Harvard Medical School, Boston, MA, United States, ⁴Surgery, Boston Children's Hospital and Harvard Medical School, Boston, MA, United States, ⁵Siemens Healthcare, ⁶Boston Children's Hospital and Harvard Medical School, Boston, MA, United States

Chronic kidney disease poses a significant health burden, and patients benefit from early detection of kidney function. Serum-creatinine based estimation is insensitive to early changes and nuclear medicine studies expose patients to radiation. In this work, we evaluated a novel technique, motion-robust high spatiotemporal resolution Dynamic Radial VIBE (DRV) with compressed sensing, to reconstruct high-quality dynamic image series, and to precisely estimate filtration rate per kidney and per voxel. Our results suggest that, compared to conventional Cartesian VIBE, DRV reconstructs higher quality motion-robust images and results in improved the goodness-of-fit to the tracer kinetic model, reducing RMSE and increasing the precision of filtration rate parameter.

Intrinsic conditions leading to renal graft dysfunction have so far been difficult to diagnose non-invasively because of the overlap in symptoms and laboratory metrics. MRI provides an accurate assessment of the morphology of the transplanted kidney, as well as of vascular or obstructive renal disorders. The long-term goal of our study is to validate functional MRI as a "virtual biopsy" by developing a multiparametric MRI protocol using advanced quantitative MRI sequences in renal transplant patients. We report initial results and test-retest repeatability of quantitative mpMRI parameters of diffusion, perfusion and hypoxia in renal allografts.

Treating male infertility: Can spectroscopy supplant biopsy in the search for sperm?

Pippa Storey¹, Oded Gonen¹, Andrew B. Rosenkrantz¹, Kiranpreet K. Khurana^{2,3}, Tiejun Zhao⁴, Rajesh Bhatta¹, and Joseph P. Alukal²

¹Radiology Department, New York University School of Medicine, New York, NY, United States, ²Urology Department, New York University School of Medicine, New York, NY, United States, ³Urology Department, Case Western Reserve University, Cleveland, OH, United States, ⁴Siemens Healthcare, New York, NY, United States

Many men who wish to start a family but lack sperm in their semen undergo surgical exploration of the testes in the hope of extracting sperm at source. However, there are currently no tests that can accurately predict whether sperm will be found. We performed proton spectroscopy at 3T in the testes of eight infertile patients and nine controls. Choline concentrations were significantly lower in patients (mean 1.4mM, range 0.8 – 1.9mM) than controls (mean 4.1mM, range 3.0 – 5.1mM), p<0.0001. This suggests that choline, which is a marker of membrane synthesis and cell proliferation, may be useful for detecting spermatogenesis noninvasively.

Machine Learning to Identify Sarcomatoid De-Differentiation in Renal Cell Carcinoma by Multiparametric MRI

Nicolas Rognin¹, Daniel Jeong², Jasreman Dhillon³, Michael Poch⁴, and Natarajan Raghunand¹

¹Department of Cancer Imaging & Metabolism, Moffitt Cancer Center, Tampa, FL, United States, ²Department of Diagnostic & Interventional Radiology, Moffitt Cancer Center, Tampa, FL, United States, ³Department of Anatomic Pathology, Moffitt Cancer Center, Tampa, FL, United States, ⁴Department of Genitourinary Oncology, Moffitt Cancer Center, Tampa, FL, United States

We developed a machine learning application to detect renal cell carcinoma (RCC) tumors with sarcomatoid de-differentiation, a rare form of aggressive cancer with poor prognosis. Proof-of-concept was demonstrated by analyzing multiparametric MRI volumetric data of 24 tumors, of which 11 were sarcomatoid RCC and 13 were non-sarcomatoid clear cell RCC. Our machine correctly classified 10 out of 11 sarcomatoid RCC cases (91% sensitivity) and 10 out of 13 clear cell RCC cases (77% specificity), with an overall classification accuracy of 20 out of 24 tumors (83%).

Apparent diffusion coefficient histogram shape analysis for monitoring early response in patients with advanced cervical cancers undergoing concurrent chemoradiotherapy

Zhengyang Zhou¹, Jian He², Weibo Chen³, and Lijing Zhu⁴

¹Department of Radiology, Drum Tower Hospital, School of Medicine, Nanjing University, Nanjing, People's Republic of China, ²Department of Radiology, Drum Tower Hospital, School of Medicine, Nanjing University, ³Philips Healthcare, Shanghai, People's Republic of China, ⁴Department of Oncology, Drum Tower Hospital, School of Medicine, Nanjing University

Thirty-two patients with advanced cervical cancer underwent DWI before CCRT, at the end of 2nd and 4th week during CCRT and immediately after CCRT completion to explore whether ADC histogram shape could assess the treatment response. Whole lesion ADC histogram analysis generated several histogram shape including skewness, kurtosis, s-sDav, width, standard deviation, as well as first-order entropy and second-order entropies. Skewness and kurtosis both showed high early decline rate at the end of 2nd week of CCRT. All entropies kept decreasing since 2 weeks after CCRT. ADC histogram shape analysis held the potential in monitoring early tumor response during CCRT.

Computer 84

Evaluation of renal allograft function after transplantation using diffusion kurtosis imaging

Wangxing Fu¹, Dandan Zheng², Jingliang Cheng¹, Yingyu Che¹, and Chunxiao Bu¹

¹MRI, The First Affiliated Hospital of ZhengZhou University, ZhengZhou, People's Republic of China, ²MR Research China, GE Healthcare, Beijing, People's Republic of China

To evaluate the feasibility of DKI in assessment of renal allograft function after transplantation, 13 patients with renal allograft underwent DKI of kidneys, which were divided into two groups according to eGFR. Maps of fractional anisotropy FA, MK, Ka, Kr and MD were generated. There was significant differences in FA, MK, Ka, Kr values of both the cortex and medulla of kidney between two groups. There was significant correlation between eGFR and cortical FA, MK, Ka, Kr, medullary FA, Ka. DKI could be a useful tool in the evaluation of renal function in allograft after transplantation.

Whole-Tumor Quantitative Apparent Diffusion Coefficient Histogram and Texture Analysis to Differentiation of Minimal Fat Angiomyolipoma from Clear Cell Renal Cell Carcinoma

Anqin Li¹, Zhen Li¹, Haojie Li¹, and Daoyu Hu¹

¹Department of Radiology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, People's Republic of China

The purpose of this study was to determine whether whole-tumor ADC histogram and texture analysis is helpful for distinguishing MFAML from ccRCC. The differences of ADC histogram and texture parameters between MFAML and ccRCC were compared using the independent-sample t test. There were significant differences on ADCmean, ADCmedian, ADC25%, ADC75%, ADC90% and skewness between MFAML and ccRCC. The ADC90% derived from the whole-tumor ADC histogram analysis showed the best diagnostic value in discriminating MFAML and ccRCC. Therefore, whole-tumor ADC histogram and texture parameters can be used as a quantitative tool to distinguish MFAML from ccRCC.

The Cortico-Medullary ADC Difference reduces inter-system variability in Renal Diffusion-Weighted Imaging

Iris Friedli¹, Lindsey A Crowe¹, Bénédicte MA Delattre², Thomas De Perrot², Pierre-Yves Martin², Sophie De Seigneux², and Jean-Paul Vallée²¹Radiology, University of Geneva, Geneva, Switzerland, ²Geneva University Hospitals

Our goal was to determine if the cortico-medullary Apparent Diffusion Coefficient difference (Δ ADC), that previously exhibited a strong correlation with renal fibrosis, is independent of MR system. Comparison of ADC (cortex, medulla and Δ) over Siemens (1.5T AERA, 3T PRISMA, 3T SKYRA) and Philips (1.5T INGENIA, 3T PET-MR) systems was carried out in eight volunteers. Significant ADC differences were measured for the cortex and medulla independently using PRISMA and AERA and, for cortex of AERA and INGENIA ($p < 0.05$). Δ ADC corrected inter-scanner variability with no significant differences across all MR systems ($p > 0.05$).

Kidney tumor characterization with diffusion-MRI: diffusion-tensor and tri-exponential modeling

Sophie van Baalen¹, Marino Asselman², Caroline Klazen³, Martijn Froeling⁴, Frank F.J. Simonis¹, Bart Vroeling¹, and Bennie ten Haken¹¹Faculty of Science and Technology, University of Twente, Enschede, Netherlands, ²Urology, Medisch Spectrum Twente, Enschede, Netherlands, ³Radiology, Medisch Spectrum Twente, Enschede, Netherlands, ⁴Radiology, University Medical Center Utrecht, Utrecht, Netherlands

We present preliminary results of our study into the characterization of kidney tumors using diffusion derived parameters. We have acquired DTI and IVIM sequences and fitted the diffusion tensor and tri-exponential model to obtain parameters FA, MD, f_{fast} , $f_{\text{intermediate}}$ and D. Among the first four patients planned for nephrectomy for suspected kidney tumor we found three RCCs, one cyst and one hemangioma. f_{fast} , the fraction of the diffusion signal that reflects fast fluid motion, is lower in non-malignant lesions, whereas D is lower in the two cc-RCCs. The differences in parameter values between lesion types are reflected in parameter maps.

3300

Computer 90

Diffusion Tensor Imaging (DTI) in the Differential Diagnosis of Clear Cell Renal Cell Carcinoma (ccRCC) and infiltrative Transitional Cell Carcinoma (TCC)

mingzhe Xu¹, ailian Liu, meiyu Sun, lihua Chen, and bing Wu²¹First Affiliated Hospital of Dalian Medical University, Dalian, People's Republic of China, ²GE healthcare China, Beijing, People's Republic of China

It's difficult to differentiate intrarenal transitional cell carcinoma from centrally located renal cell carcinoma by contrast enhanced CT when the tumor composition is complex. In this study, DTI were performed to investigate the utility of the apparent diffusion coefficient (ADC) and fractional anisotropy (FA) values for differential diagnosis of ccRCC and infiltrative TCC, thus assessing the sensitivity and specificity of ADC and FA values. The FA value from DTI, which reveals the different structure of tumors, provides an effectively non-invasive means to distinguish ccRCC from TCC because of its good sensitivity.

Computer 91

Does PROPELLER acquisition improve bladder imaging by substantially reducing motion artifacts?

Huyen Thanh Nguyen¹, Zarine K Shah¹, Lai Wei², and Michael V Knopp¹¹Wright Center of Innovation in Biomedical Imaging, Department of Radiology, The Ohio State University, Columbus, OH, United States, ²Center for Biostatistics, The Ohio State University, Columbus, OH, United States

This study is to evaluate the clinical application of PROPELLER reconstruction technique to reduce breathing-induced motion artifacts in bladder imaging. High resolution T2W images were acquired with and without multivane (PROPELLER technique) in fourteen patient scans. Image quality was assessed by a radiologist in terms of motion artifacts and the visualization of tumor margins. Scores were given in the range of 1 to 4. The results showed that the application of multivane significantly improved both motion artifacts and tumor visualization (both $P < 0.001$). In conclusion, PROPELLER reconstruction is a robust technique to substantially reduce the artifacts caused by unavoidable breathing motion to provide the delineation of bladder tumors against surrounding tissues.

Phosphorescence Lifetime Imaging to validate BOLD MRI Derived blood PO₂Jon Thacker¹, Anthony E. Felder², Pottumarthi V Prasad^{1,3,4}, and Mahnaz Shahidi²¹Northwestern University, Evanston, IL, United States, ²University of Illinois at Chicago, ³NorthShore University HealthSystem, ⁴University of Chicago

BOLD MRI measurements are the only non-invasive method sensitive to renal oxygenation. In a previous study we showed that BOLD MRI measurements can be combined with a statistical model to estimate renal oxygenation in rat kidneys. In this study, we examine the use of phosphorescence lifetime imaging (PLI) as a potential method for refining the model. It is important to differentiate between blood and tissue PO₂, which is a key benefit of PLI. We found that the PLI is sensitive to changes following LNAME. However, the absolute PO₂ values were lower than those estimated by BOLD MRI and possible reasons are discussed.

3303

Computer 93

Detectability of oxygen saturation in renal blood using intravoxel incoherent motion (IVIM) imaging

Tatsuo Nagasaka¹, Hideki Ota², Hitoshi Nemoto¹, and Hajime Tamura³¹Radiology, Tohoku University Hospital, Sendai, Japan, ²Diagnostic Radiology, Tohoku University Hospital, Sendai, Japan, ³Graduate School of Medicine, Tohoku University, Sendai, Japan

IVIM imaging acquired with two echo times may provide transverse relaxation time of blood fraction, which can be converted to blood oxygen saturation. We confirmed consistent increases in the renal blood oxygen saturation estimated by this method after an oral water load. IVIM imaging may become a non-invasive method to estimate blood oxygen saturation in kidneys.

Metabolomic Analysis by HRMAS-MRS: Preliminary Study for Tumor Diagnosis

Francesco L Palmas^{1,2}, Sarah L Prophet³, Lindsey L Vandergriff³, Taylor L. Fuss³, Shulin Wu³, Chin-Lee Wu³, Adam Feldman³, and Leo L. Cheng³

¹Pathology, Massachusetts General Hospital, Charlestown, MA, United States, ²Chemical and Geological Sciences, University of Cagliari, Cagliari, Italy, ³Massachusetts General Hospital, Charlestown, MA, United States

Kidney cancer is the third most common genitourinary malignancy in the US and leads to over 14,000 deaths and over 61,000 new cancer diagnoses per year. Since metabolic pathways affect the development of several malignancies, MRS was applied to highlight the existing alteration between adjacent benign and cancer tissues. Furthermore, comparison of fresh-frozen paired samples was performed to assess whether such strategy may interfere and deliver different results. This approach was able to discriminate according to pathological condition (benign-tumor) and showed no significant differences in fresh-frozen pairs.

Optimized 3D ultrashort echo-time lung imaging of young children without sedation

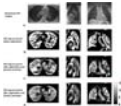

Wingchi Edmund Kwok¹, Jacqueline Wameling¹, Mitchell Chess¹, Clement Ren², Gloria Pryhuber¹, and Jason C. Woods³

¹University of Rochester, Rochester, NY, United States, ²Indiana University, Indianapolis, IN, United States, ³Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States

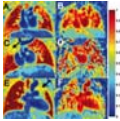

Our purpose was to develop an optimized study design for 3D ultrashort TE lung imaging of young children without sedation. Eight preterm born subjects all at age 4 were recruited. Siemens work-in-progress PETRA_D sequence was used with respiratory triggering. Repeated short scans were acquired to reduce motion artifacts. Various techniques, including video watching, practicing lying still at home and gift incentive, were employed to help achieve subject compliance. Five subjects were scanned successfully. The images revealed abnormalities including peribronchial thickening, pneumatocele and atelectasis. Our study design allows the monitoring of lung development and evaluation of lung diseases in young children.

- Dual-echo ultrashort echo-time CODE pulmonary MRI preliminarily succeeded in generating a positive contrast of iron oxide in rabbits with granulomatous lung disease, by using clinically-usable superparamagnetic iron-oxide nanoparticles, ferumoxytol, which was hardly achievable via conventional T2* MR sequence. This new pulmonary MR imaging biomarker possibly gives a chance to differentiate a benign inflammatory lesion from malignancy.

-
- 3310 **Computer 100**  **Repeatability of global percent enhancement and regional defect quantification in oxygen-enhanced 3D radial ultrashort echo time MRI**
Wei Zha¹, Stanley J Kruger¹, Kevin M Johnson^{1,2}, Robert V Cadman¹, Andrew D Hahn¹, Scott K Nagle^{1,2,3}, and Sean B Fain^{1,2,4}
- ¹Medical Physics, University of Wisconsin-Madison, Madison, WI, United States, ²Radiology, University of Wisconsin-Madison, Madison, WI, United States, ³Pediatrics, University of Wisconsin-Madison, Madison, WI, United States, ⁴Biomedical Engineering, University of Wisconsin-Madison, Madison, WI, United States
- Oxygen-enhanced 3D radial UTE MRI (OE-MRI) shows promise as an alternative to hyperpolarized gas MRI for evaluation of ventilation abnormalities. Ten subjects (2 normal, 2 asthmatics and 6 cystic fibrosis) underwent OE-MRI for multiple scans (test/re-test) during visits separated ≤ 15 days apart. The intra-subject percent signal enhancement (PSE) maps from OE-MRI were compared for median whole-lung PSE, ventilation defect percent (VDP) and spatial agreement between defects. The results suggest good agreement on two global measures, Median PSE and VDP, with low-to-moderate spatial alignment on the inter-visit segmented defects. Improvement of spatial defect repeatability will be a goal of future work.

-
- 3311 **Computer 101**  **Repeatability of regional lung ventilation quantification using ¹⁹F fluorinated gas washout magnetic resonance imaging in free breathing**
Marcel Gutberlet^{1,2}, Andreas Voskrebenzev^{1,2}, Agilo Kern^{1,2}, Till Kaireit^{1,2}, Jens Hohlfeld^{2,3}, Frank Wacker^{1,2}, and Jens Vogel-Claussen^{1,2}
- ¹Institute of Radiology, Hannover Medical School, Hannover, Germany, ²Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Hannover, Germany, ³Clinical Airway Research, Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany
- Since quantification of regional lung ventilation using ¹⁹F fluorinated gas washout imaging in free breathing is feasible even in obstructed lungs, it may improve diagnosis, monitoring and therapy of obstructive lung diseases like asthma and COPD. However, for application in clinical studies the knowledge of the accuracy of this technique is important. Repeatability of the ¹⁹F gas washout parameters washout time, number of breaths and fractional ventilation between to scans was assessed in eight healthy volunteers. Due to the excellent repeatability of the number of breaths and fractional ventilation, regional lung ventilation can be accurately quantified using ¹⁹F gas washout MRI in free breathing.

-
- 3312 **Computer 102**  **MR Elastography vs. Diffusion-weighted MRI in Characterization of Anterior Mediastinal Solid Tumours**
Wei Tang¹, Ning Wu¹, and Yao Huang¹
- ¹Diagnostic Radiology, Cancer Hospital, Chinese Academy of Medical Sciences, Peking Union Medical College, Beijing, People's Republic of China
- Anterior mediastinal solid tumours were routinely interpreted on CT and MR imaging. However, imaging features of these tumours could be non-specific; evidence suggestive of definitive diagnosis was needed and obtained with invasive procedure of biopsy for some cases. In the present study, we attempted to extend the application of MR elastography to the mediastinum in characterization of anterior mediastinal solid tumours, with the comparison to diffusion-weighted MRI. Thirty-four patients histologically-confirmed with thymic carcinoma in 10, thymoma in 10 and lymphoma in 14 were evaluated. It was found that stiffness value measured on elastogram was significantly higher in thymic carcinoma than that of thymoma and lymphoma. However, measurements of apparent diffusion coefficient (ADC) were not significantly different among three groups. It was demonstrated that MR elastography reflecting the mechanical properties of tumours can be used to characterize anterior mediastinal solid tumours, particularly in distinguishing thymic carcinoma from lymphoma.

Computer 104

Diagnosing Lung Nodules on various MRI Imaging: comparison of T1-Weighted-3D VIBE-dixon sequence and T1-weighted 3D star vibe sequence

Chuangbo Yang¹, Nan Yu, Qi Yang, Shaoyu Yu, Youmin Guo, and Liya Ma

¹The first affiliated hospital of Shaanxi traditional chinese medical university, Xian Yang, People's Republic of China

T1-weighted 3D Star VIBE sequence obtaining scan under free breathing can provide high-resolution imaging. Therefore, our study was to assess the accuracy of various MRI sequences for the diagnosis of pulmonary nodules and to estimate the ability of MRI for display the morphology of pulmonary nodules. We concluded that T1-weighted 3D Star VIBE sequence allow for identification of patients with pulmonary nodules with high detection rate. It can also provide more information of nodules than routine T1-weighted 3D VIBE sequence dose.

3315

Computer 105

Exploring Lung Inflation Mechanisms with 3D 3He and 129Xe Whole Lung Morphometry Mapping

Ho-Fung Chan¹, Juan Parra-Robles^{1,2}, Guilhem J Collier¹, and Jim M Wild¹

¹Academic Unit of Radiology, University of Sheffield, Sheffield, United Kingdom, ²Department of Bioengineering, Universidad Carlos III de Madrid, Madrid, Spain

Alveolar dimensions change with lung inflation, however, there is currently no consensus on whether this change is primarily due to expansion and if alveolar recruitment plays a role. Here, multiple b-value DW-MRI was used to investigate lung inflation mechanisms in-vivo, and 3D ³He and ¹²⁹Xe whole lung morphometry (L_m) maps were acquired in five healthy volunteers at lung inflation states of FRC+1L and TLC. Decreases in the anterior to posterior gravitational gradient were observed between FRC+1L and TLC with both nuclei. Smaller than predicted L_m values at TLC suggests that both alveolar expansion and recruitment may occur during lung inflation.

Self-gated ultra-short echo time lung MRI for quantitative ventilation assessment

Lenon Mendes Pereira¹, Tobias Wech¹, Andreas M. Weng¹, Andreas S. Kunz¹, Simon Veldhoen¹, Thorsten A. Bley¹, and Herbert Köstler¹

¹Department of Diagnostic and Interventional Radiology, University Hospital Würzburg, Würzburg, Germany

Self-gated Non-Contrast-enhanced Functional Lung MRI (SENCEFUL) is a technique based on a FLASH sequence that can assess ventilation and perfusion in free-breathing without the use of contrast agents. However, SENCEFUL suffers from the fast T₂-induced signal decay in the lung parenchyma and offers no real 3D coverage. Thus, this work presents the use of a 3D ultra-short echo time (UTE) sequence in SENCEFUL MRI for the generation of ventilation-weighted maps.

To examine the association of ventilation defects on 3He MRI with emphysema subtypes, participants (n=41) between 60 and 85 years of age with 10 or more packyears of smoking were studied. Ventilation defect percentage (VDP) was associated with percent emphysema ($r=0.43$; $p=0.008$) and, with borderline statistical significance, extent of visual emphysema ($r=0.31$; $p=0.07$). There was no relationship between VDP and extent of centrilobular ($p=0.61$) or panlobular ($P=0.98$) emphysema. VDP was associated with extent of paraseptal emphysema (PSE) ($r=0.42$; $p=0.01$). These findings suggest that small airways disease may be a component of PSE but not other subtypes of emphysema.

¹Robarts Research Institute, London, ON, Canada, ²Division of Respiriology, The University of Western Ontario, London, ON, Canada

UTE MRI signal-intensity has not yet been evaluated in young patients with AATD and BPD, where there may be different mechanisms of parenchyma and airway destruction. There is the potential to demonstrate UTE MRI as a quantitative-measurement-tool for longitudinal and treatment-response evaluations in these vulnerable patients. We evaluated UTE MRI and CT using -950HU and -856HU radiodensity-thresholds, and a 'sliding-threshold' for the UTE image, identifying regions with low-signal-intensity for multiple threshold values. Regions of normalized UTE signal-intensity <29 suggest airspace enlargement, and demonstrate the potential utility of UTE MRI in quantifying this without ionizing-radiation in AATD and BPD subjects.

3322

Computer 112 T2* Quantification of the Lung Using 3D Ultrashort Echo Time Cones Sequences

Imaging of the lungs without a contrast agent is a challenging task due to the low SNR. The main challenge stems from the air in the lungs, which causes low proton density and high magnetic susceptibility at interfaces with tissue. Ultra short echo time (UTE) techniques have the potential to acquire high signal-to-noise ratio (SNR) images due to their short achievable TEs, much less than 1ms. The lung imaging based on 3D radial UTE sequences were previously reported. In this work, we applied three-dimensional UTE with Cones trajectories (3D UTE-Cones) to quantify lungs' tissue.

3323

Computer 113 Self-gated Non-Contrast-Enhanced Functional Lung (SENCEFUL) MRI for Evaluation of Endoscopic Lung Volume Reduction in Patients with Lung Emphysema

Simon Veldhoen¹, Andreas Max Weng¹, Tobias Wech¹, Andreas Steven Kunz¹, Stephanie Sauer¹, Thorsten Alexander Bley¹, and Herbert Köstler¹

¹Department of Diagnostic and Interventional Radiology, University Hospital Würzburg, Würzburg, Germany

Purpose of the study was to assess the feasibility of SENCEFUL ventilation imaging for evaluation of therapy success after endoscopic lung volume reduction. Two patients with lung emphysema who underwent bronchial valve implantation were scanned before and after the procedure using SENCEFUL-MRI. Color-coded lung ventilation maps and quantitative ventilation values were pre- and postinterventionally compared. The first patient showed a ventilation defect corresponding to the location of the implanted valves with reduction of the quantitative ventilation. The second patient did not present such alterations and was later classified as non-responder to therapy. SENCEFUL-MRI detected clinically successful and non-successful outcomes correctly.

3324

Computer 114 Single Breath CSSR-DWI: A New Method to Simultaneously and Quantitatively Assess the Changes of Respiratory Membrane and Pulmonary Microstructure in Human

Junshuai Xie¹, Huiting Zhang¹, Xiuchao Zhao¹, Haidong Li¹, Sa Xiao¹, Ke Wang², Hao Yang², Xianping Sun¹, Guangyao Wu², Chaohui Ye¹, and Xin Zhou¹

¹Key Laboratory of Magnetic Resonance in Biological Systems, State Key Laboratory of Magnetic Resonance and Atomic and Molecular Physics, National Center for Magnetic Resonance in Wuhan, Wuhan Institute of Physics and Mathematics, Chinese Academy of Sciences, Wuhan, People's Republic of China, ²Department of Radiology, Zhongnan Hospital of Wuhan University, Wuhan, People's Republic of China

The blood-gas exchange function and the pulmonary microstructure are generally affected by the lung inflation levels. Here We developed a new method Single Breath CSSR-DWI to simultaneously quantify the respiratory membrane and the pulmonary microstructure via hyperpolarized ^{129}Xe in a single breath. A new parameter SVRd/g was defined from ADC and SVRd to characterize the “%-predicted dissolved SVR”. Human pulmonary functional and structure information were successfully obtained in a single breath via hyperpolarized ^{129}Xe . Compared to the healthy young subjects, SVRd/g of the asymptomatic aged subjects decreases while the size of the pulmonary microstructure increases.

3325

Computer 115

Quantify Pulmonary Gas-Exchange Function with Hyperpolarized ^{129}Xe CEST MRI

Haidong Li¹, Zhiying Zhang¹, Xiuchao Zhao¹, Yeqing Han¹, Xianping Sun¹, Chaohui Ye¹, and Xin Zhou¹

¹Key Laboratory of Magnetic Resonance in Biological Systems, State Key Laboratory of Magnetic Resonance and Atomic and Molecular Physics, National Center for Magnetic Resonance in Wuhan, Wuhan Institute of Physics and Mathematics, Chinese Academy of Sciences, Wuhan, People's Republic of China

In this study, the pulmonary gas-exchange function was quantitatively evaluated globally and regionally by hyperpolarized ^{129}Xe MRI using the method of chemical exchange saturation transfer (CEST). A new parameter, named as pulmonary gas consumption time constant (Toc), was proposed to characterize the gas exchange function. The parameter showed significant difference between the COPD and healthy rats, and we believe it will be a useful parameter in evaluating the pulmonary function.

Synopsis: Image registration of lung CT images acquired at different inflation levels has been proposed as a surrogate method to map lung ‘ventilation’. However, this technique requires validation against established ventilation modalities such as hyperpolarised gas MRI. Here, we develop an image acquisition and analysis strategy to facilitate direct spatial correlation of ventilation CT with both hyperpolarised ^3He & ^{129}Xe MRI and apply our method to a cohort of lung cancer patients.

Computer 117

Evaluation of ^{129}Xe -RBC signal dynamics and chemical shift in the cardiopulmonary circuit using hyperpolarized ^{129}Xe NMR

Graham Norquay¹, Neil J Stewart¹, and Jim M Wild¹

¹Academic Unit of Radiology, University of Sheffield, Sheffield, United Kingdom

The signal dynamics of hyperpolarized ^{129}Xe in the pulmonary capillaries and veins was evaluated by employing multi-TR pulse sequences, with TR values ranging from 100-6000ms. The ratio of signal from ^{129}Xe dissolved in red blood cells (RBC) and tissue/plasma (TP) was found to increase for longer TRs whilst the ^{129}Xe -RBC chemical shift was observed to decrease with increasing TR. This observed chemical shift difference is unprecedented, and understanding the nature of the underlying mechanisms causing this shift is crucial for future in vivo experiments using ^{129}Xe -RBC chemical shift as a measure of blood oxygenation.

¹Academic Unit of Radiology, University of Sheffield, Sheffield, United Kingdom, ²Academic Directorate of Respiratory Medicine, Sheffield Teaching Hospitals, Sheffield, United Kingdom, ³Infection, Immunity and Cardiovascular Disease, University of Sheffield, Sheffield, United Kingdom

Outcome metrics from diffusion-weighted MRI (DW-MRI) were evaluated for reproducibility and clinical correlation in a cohort of patients with idiopathic pulmonary fibrosis (IPF). It was hypothesized that fibrotic lung tissue in IPF undergoes changes that increase the rate of intra-acinar Brownian diffusion.

Apparent diffusion coefficient (ADC) mean, median and histogram metrics are highly reproducible and correlate both quantitatively with regional fibrosis on CT and qualitatively with carbon monoxide transfer coefficient (KCO) from pulmonary function tests. DW-MRI imaging metrics may provide novel insights into microstructural disease severity in IPF and may prove to be a useful non-ionising imaging biomarker of disease.

Hyperpolarized xenon by d-DNP using the clinical GE SpinLab polarizer system

Christian Østergaard Mariager¹, Steffen Ringgaard¹, Jan Henrik Ardenkjær-Larsen^{2,3}, and Christoffer Laustsen¹

¹Department of Clinical Medicine, The MR Research Centre, Aarhus University Hospital, Aarhus N, Denmark, ²Department of Electrical Engineering, Center for Hyperpolarization in Magnetic Resonance, Technical University of Denmark, Kgs. Lyngby, Denmark, ³GE Healthcare, Denmark

Hyperpolarized (HP) ^{129}Xe have been demonstrated as a useful probe for magnetic resonance (MR) lung imaging and show promise for in vivo perfusion imaging and brown adipose tissue characterization. Reports of large polarization enhancements for ^{129}Xe using dynamic nuclear polarization (DNP) have raised expectations that DNP can be an alternative to the standard spin exchange optical pumping (SEOP) method. We show that it is possible to produce HP ^{129}Xe gas using the clinical GE SpinLab polarizer, thus extending the practical use of the system beyond the primary purpose of hyperpolarizing liquid biomolecules.

Combination of Variable and Constant Flip Angles for Hyperpolarized ^{129}Xe Multi-b Diffusion MRI in a Single Breath-hold
Weiwei Ruan^{1,2}, Jianping Zhong¹, Ming Zhang¹, He Deng¹, Yeqing Han¹, Chaohui Ye¹, and Xin Zhou¹

¹Key Laboratory of Magnetic Resonance in Biological Systems, State Key Laboratory of Magnetic Resonance and Atomic and Molecular Physics, National Center for Magnetic Resonance in Wuhan, Wuhan Institute of Physics and Mathematics, Chinese Academy of Sciences, Wuhan, People's Republic of China, ²University of Chinese Academy of Sciences, Beijing, People's Republic of China

To propose a novel flip angle scheme for hyperpolarized gas multi-b diffusion MRI. It combined the variable and constant flip angles and was named as the combination of variable and constant flip angle (CVCFA). Computer simulation was used to systematically compare the proposed flip angle scheme with the common-used flip angle schemes, including the interleaved constant flip angle (ICFA) and the variable flip angle (VFA) schemes. The CVCFA scheme was used for hyperpolarized xenon diffusion MRI to measure the pulmonary morphology in rats, noninvasively. The results showed the CVCFA was suited for the hyperpolarized gas multi-b diffusion MRI.

Multi-shot Diffusion Imaging using 1D Navigator Acquisition with Parallel Imaging and Iterative Reconstruction
Zhe Zhang¹, Xiaodong Ma¹, Erpeng Dai¹, and Hua Guo¹

¹Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China

Multi-shot EPI can achieve high resolution diffusion imaging but shot-to-shot phase variation correction is indispensable. Previous multi-shot EPI diffusion imaging methods can be categorized into two groups based on different phase navigation strategies: navigator acquired from a second echo and navigator calculated from image-echo itself using parallel imaging technique. These methods may suffer prolonged scan time or limitation from high reduction factor penalty. In this work, we proposed a new strategy for efficient navigating in multi-shot DWI using 1D navigator acquisition with parallel imaging and iterative reconstruction. Results show the proposed methods can effectively correct the motion-induced artifacts in diffusion imaging.

Joint Non-local Means Reconstruction for Correction of Phase-Induced Errors in Diffusion Tensor Imaging
Sevgi Gokce Kafali^{1,2}, Tolga Cukur^{1,2}, and Emine Ulku Saritas^{1,2}

¹Electrical and Electronics Engineering, Bilkent University, Ankara, Turkey, ²National Magnetic Resonance Research Center (UMRAM), Ankara, Turkey

Multiple acquisitions have to be averaged to achieve reasonable signal-to-noise ratio (SNR) in high-resolution diffusion tensor imaging (DTI). However, involuntary global/local motions during diffusion-sensitizing gradients create k-space shifts, and global/local phase differences between different acquisitions, complicating image reconstruction. In this work, we propose a phase-correcting joint non-local means reconstruction that effectively prevents phase cancellations and reduces noise. This technique jointly utilizes the images from different diffusion-encoding directions to preserve the fractional anisotropy (FA) map. Results are demonstrated for in vivo spinal cord DTI and on a simulated DTI dataset.

Accelerating Diffusion Kurtosis Imaging Using Model Based Denoising

Jonathan I Sperl¹, Tim Sprenger^{1,2}, Ek T Tan³, Marion I Menzel¹, Christopher J Hardy³, and Luca Marinelli³

¹GE Global Research, Garching, Germany, ²Technische Universität München, Munich, Germany, ³GE Global Research, Niskayuna, NY, United States

Diffusion Kurtosis Imaging (DKI) suffers from high sensitivity to noise and therefore requires long scanning times (up to 150 diffusion weighted images, DWIs). This work proposes a model-based denoising technique to overcome this limitation: A generalized multi-shell spherical deconvolution model is formulated and DWIs are denoised by a projection into the space spanned by the model. We demonstrate noise reduction for DKI metrics yielding improved image quality of kurtosis maps from as few as 30 DWIs. This corresponds to greater than four-fold reduction in scan time as compared to the widely used 140-DWI acquisitions.

Improved Reconstruction for Simultaneous Multi-Slice (SMS) Accelerated Interleaved EPI DWI
Erpeng Dai¹, Xiaodong Ma¹, Zhe Zhang¹, Chun Yuan^{1,2}, and Hua Guo¹

¹Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China, ²Vascular Imaging Laboratory, Department of Radiology, University of Washington, Seattle, WA, United States

Recently, simultaneous multi-slice (SMS) has been proved to be effective for accelerating single-shot EPI (ssh-EPI) based diffusion weighted imaging (DWI). More importantly, SMS can be combined with multi-shot interleaved EPI (iEPI) DWI to achieve high resolution and high throughput simultaneously. However, signal dropout problems may exist in the final DW images, especially at high SMS acceleration factors. The main reason is the prominent cerebrospinal fluid (CSF) pulsation, which may degrade the reconstruction performance. In this study, the reconstruction algorithm is augmented by using iteration and data rejection. In-vivo experiments have demonstrated that the augmented algorithm can effectively alleviate the signal dropout problems.

The Effects of 2D Navigator Distortion and Noise Level on Interleaved EPI DWI Reconstruction: A Simulation Study
Erpeng Dai¹, Xiaodong Ma¹, Zhe Zhang¹, Chun Yuan^{1,2}, and Hua Guo¹

¹Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China, ²Vascular Imaging Laboratory, Department of Radiology, University of Washington, Seattle, WA, United States

Interleaved EPI (iEPI) with a 2D navigator is an effective way to acquire high-resolution and less-distorted DWI. The inter-shot phase variations can be corrected with acquired 2D navigator. However, the performance is limited by the geometric distortion mismatch between the navigator-echo and image-echo. Parallel imaging can be used to reduce the navigator distortion, but can cause noise amplification. Previously, the effects of the navigator were studied with in vivo experiments, but the effects of distortion and noise were mixed together. In this study, the effects of navigator distortion and noise are studied individually with both DWI and DTI simulations.

3336

Computer 6

Improved Navigator-free Multi-shot DTI Reconstruction with Inter-image Correlation Constraint
Xiaodong Ma¹, Zhe Zhang¹, Erpeng Dai¹, Chun Yuan^{1,2}, and Hua Guo¹

¹Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, China, Beijing, People's Republic of China, ²Vascular Imaging Laboratory, Department of Radiology, University of Washington, Seattle, WA, United States

To improve the image quality for navigator-free multi-shot DTI reconstruction, the inter-image correlation constraint is introduced. Group sparsity and anisotropic sparsity are proposed as two specific implementations, using the POCS-ICE algorithm. Results show that both constraints can improve the image quality with increased SNR. In addition, anisotropy sparsity has less blurring and can better maintain the detailed structures.

3337

Computer 7

Rotating Single-shot Acquisition (RoSA) combined with parallel imaging for fast high-resolution diffusion imaging

Qiuting Wen¹, Brian Dale², Shivraman Giri³, and Yu-Chien Wu¹

¹Radiology and Imaging Science, Indiana University, Indianapolis, IN, United States, ²Siemens Medical Solutions, Inc., Hanover, NH, United States, ³Siemens Medical Solutions, Inc., Morrisville, NC, United States

High-resolution diffusion-weighted MRI often relies on multi-shot acquisitions, which suffer from long acquisition time. Rotating single-shot acquisition (RoSA) was proposed to accelerate high-resolution diffusion MRI by taking advantage of the similarity between diffusion-weighted images. In RoSA only a strip of k-space (i.e., blade) per diffusion direction is acquired, and high-resolution image was achieved via composite reconstruction. In this work, we implemented RoSA with parallel imaging. We demonstrated that improved data quality and imaging speed was achieved in both simulation and in human data.

3338

Computer 8

Diffusion imaging with intra volume interleaving of b values

Jana Hutter¹, Paddy J Slator², Anthony N Price³, Ana Dos Santos Gomes⁴, Laura McCabe⁴, Maria Murgasova Kuklisova⁵, Paul Aljabar¹, Mary Rutherford⁴, and Joseph V Hajnal³

¹Biomedical Engineering, King's College London, London, United Kingdom, ²Centre for Medical Image Computing, University College London, London, United Kingdom, ³Biomedical Engineering Department, King's College London, London, United Kingdom, ⁴Centre for the Developing Brain, King's College London, London, United Kingdom, ⁵Perinatal Imaging, King's College London, London, United Kingdom

Conventional diffusion MRI acquisitions acquire all slices per volume with the same diffusion weighting. This can have two drawbacks: Excessive heating of gradient hardware caused by multiple repeats of the same combination of large drive currents, and low signal at high b-values, which impairs motion correction based on image registration. For placental diffusion MRI, where large slice stack are needed for spatial coverage and anatomical structure can be lost after diffusion, both of these factors can be extreme. We propose intra-volume interleaving of different diffusion weightings, ordered to facilitate image registration for motion correction and minimise gradient heating.

3339

Computer 9

Randomizing simultaneously excited slice groups in SMS to reduce slice leakage artifacts in diffusion MRI

Daniel Olson¹, Andrew Nencka², Volkan Arpinar², and L. Tugan Muftuler³

¹Biophysics, Medical College of Wisconsin, Milwaukee, WI, United States, ²Radiology, Medical College of Wisconsin, Milwaukee, WI, United States, ³Neurosurgery, Medical College of Wisconsin, Milwaukee, WI, United States

Simultaneous Multi-slice (SMS) techniques excite multiple slices simultaneously to accelerate MRI data acquisition. However, slice separation during image reconstruction is not exact and results in coupling between separated voxels. While this may not be critical for most anatomic imaging methods, small but consistent leakage of information from another slice in a DTI dataset will cause bias in diffusion parameter estimates. Here, we propose a randomized-slice pairing technique to alleviate this problem in diffusion MRI acquisitions.

3340

Computer 10

Optimal design of motion-compensated diffusion gradient waveforms

Óscar Peña-Nogales¹, Rodrigo de Luis-García¹, Santiago Aja-Fernández¹, Yuxin Zhang^{2,3}, James H. Holmes², and Diego Hernando^{2,3}

¹Laboratorio de Procesado de Imagen, Universidad de Valladolid, Valladolid, Spain, ²Radiology, University of Wisconsin-Madison, Madison, WI, United States, ³Medical Physics, University of Wisconsin-Madison, Madison, WI, United States

Diffusion-Weighted MRI (DW-MRI) often suffers from motion-related artifacts in organs that experience physiological motion. Importantly, organ motion during the application of diffusion gradients results in signal losses, which complicate image interpretation and bias quantitative measures. Motion-compensated gradient designs have been proposed, however they typically result in substantially lower b-values or severe concomitant gradient effects. In this work, we develop an approach for design of first- and second-order motion-compensated gradient waveforms based on a b-value maximization formulation including concomitant gradient nulling, and we compare it to existing techniques. The proposed design provides optimized b-values with motion compensation and concomitant gradient nulling.

3341

Computer 11

Determination of the optimal set of b-values for ADC mapping under a Rician noise assumption

Óscar Peña-Nogales¹, Diego Hernando^{2,3}, Santiago Aja-Fernández¹, and Rodrigo de Luis-García¹

¹Laboratorio de Procesado de Imagen, Universidad de Valladolid, Valladolid, Spain, ²Radiology, University of Wisconsin-Madison, Madison, WI, United States, ³Medical Physics, University of Wisconsin-Madison, Madison, WI, United States

Mapping of the apparent diffusion coefficient (ADC), estimated from a set of diffusion-weighted (DW) images acquired with different b-values, often suffers from low SNR, which can introduce large variance in ADC maps. Unfortunately, there is no consensus on the optimal b-values to maximize the noise performance of ADC map. In this work, we determine the optimal b-values to maximize the noise performance of ADC mapping by using a Cramér-Rao Lower Bound (CRLB) approach under realistic noise assumptions. The strong agreement between the CRLB-based analysis, Monte-Carlo simulations, and ADC phantom experiment, suggests the utility of this approach to optimize DW-MRI acquisitions.

3342

Computer 12

Towards Achieving the Optimal SNR Efficiency for 3D Multi-shot Diffusion-Weighted Echo-Planar Imaging

Xiaoxi Liu¹, Edward S. Hui^{1,2}, Cui Di¹, Nan-Kuei Chen^{3,4}, and Hing-Chiu Chang¹

¹Department of Diagnostic Radiology, The University of Hong Kong, Hong Kong, Hong Kong, ²The State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, Hong Kong, ³Department of Biomedical Engineering, University of Arizona, Tucson, AZ, United States, ⁴Brain Imaging and Analysis Center, Duke University Medical Center, Durham, NC, United States

Due to the assumption of 2D phase variations, the feasible maximum slab thickness is relatively thin (e.g. < 25 mm) for 3D multi-shot diffusion-weighted echo-planar imaging. We have thus proposed a new method in another study to correct for 3D inter-shot phase variations, thereby significantly increasing the feasible maximum slab thickness. In this study, we have demonstrated by simulations and experiments that slab thickness can be significantly increased to allow whole brain coverage with a TR that achieves optimal SNR efficiency.

3343

Computer 13

Field-map correction in read-out segmented echo planar imaging for reduced spatial distortion in prostate DWI – a phantom study

Robert Bergen^{1,2} and Lawrence Ryner^{1,2}

¹Physics & Astronomy, University of Manitoba, Winnipeg, MB, Canada, ²Medical Physics, CancerCare Manitoba, Winnipeg, MB, Canada

Diffusion-weighted magnetic resonance imaging (DWI) is routinely used in prostate cancer assessment, but suffers from image distortions primarily due to the tissue-air interface at the rectal cavity. Readout-segmented echo planar imaging (RESOLVE) improves image quality through segmented acquisition of k-space, increasing bandwidth in the phase direction. However, distortions of several millimeters may still exist in RESOLVE images. This study quantified distortions in a prostate phantom by varying the number of RESOLVE segments and using field mapping correction techniques. Field mapping correction decreased image distortion by 28% compared to the 7-segment RESOLVE scan.

3344

Computer 14

Simultaneous Multi-Slice Double Diffusion Encoding Imaging

Grant Kaijui Yang^{1,2}, Hua Wu³, Qiyuan Tian^{1,2}, Adam Kerr³, Robert Dougherty³, and Jennifer McNab²

¹Electrical Engineering, Stanford University, Stanford, CA, United States, ²Radiology, Stanford University, Stanford, CA, United States, ³Center for Cognitive and Neurobiological Imaging, Stanford University, CA, United States

Double diffusion encoding (DDE) sequences can measure microscopic diffusion anisotropy even in complex structures such as cortex or crossing fiber regions in white matter. However, DDE sequences require long TEs to accommodate the additional diffusion gradients, resulting in lower signal-to-noise ratio (SNR) and reduced slice coverage limiting its clinical feasibility. In this work, we implement a DDE sequence with simultaneous multi-slice (SMS) to improve the SNR efficiency and allow for full-brain DDE scans in a clinically feasible time.

3345

Computer 15

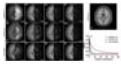

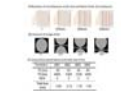

A measurement weighting scheme for optimal powder average estimation

Filip Szczepankiewicz¹, Carl-Fredrik Westin^{2,3}, and Hans Knutsson^{3,4}

¹Medical Radiation Physics, Lund University, Lund, Sweden, ²Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ³Department of Biomedical Engineering, Linköping University, Linköping, Sweden, ⁴Center for Medical Image Science and Visualization, Linköping University, Linköping, Sweden

The powder-averaged signal is used in several analysis techniques in diffusion MRI. Assuming uniformly distributed diffusion encoding directions, it is calculated simply as the arithmetic signal average. However, perfectly uniform sampling is generally unattainable.

We demonstrate how non-uniformity can be accounted for by using weighted signal averaging, and we describe how optimal weights can be calculated for existing diffusion encoding schemes to yield improved accuracy of the powder average estimate.

-
- 3346 **Computer 16** Can eddy currents and concomitant fields be compensated at the same time in flow-compensated diffusion MRI?
 Lars Mueller¹, Tristan Anselm Kuder¹, and Frederik Bernd Laun^{1,2}

¹Medical Physics in Radiology, German Cancer Research Center, Heidelberg, Germany, ²Institute of Radiology, University Hospital Erlangen
- The possibility to simultaneously compensate for flow, concomitant fields and eddy currents in diffusion weighted MRI were examined by means of numerical simulations. For this purpose, sequences with three to five gradient pulses and one or two refocusing pulses were examined. It is shown that it is possible to effectively minimize all three effects with different sequences. For short to intermediate echo times, it is beneficial to use only one refocusing pulse, while for long echo times two refocusing pulses can yield higher b-values. There is a trade-off between compensation of more effects and the achievable b-value.
-
- 3347 **Computer 17** A new method for the image reconstruction of multi-shot navigator-free DWI
 Zhangxuan Hu¹, Chun Yuan^{1,2}, and Hua Guo¹

¹Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China, ²Department of Radiology, University of Washington, 1959 NE Pacific Street, SS-202, Seattle, WA 98195-7117, USA, WA, United States
- Multi-shot techniques can help to achieve high spatial resolution in diffusion imaging. Due to the application of diffusion gradients, phase errors are induced by shot-to-shot motions, which need to be corrected during image reconstruction. Some phase correction approaches have been proposed, such as SENSE+CG, POCS-ICE, and PR-SENSE. Compressed sensing (CS) method has been used in image reconstruction and shows great insensitivity to noise, and can be effectively solved by the Alternating Direction Method of Multipliers (ADMM) algorithm. In this work, the ADMM method of CS reconstruction is used in multi-shot diffusion imaging and proved that it can provide higher reconstruction quality.
-
- 3348 **Computer 18** Simultaneous multi-slice (SMS) echo planar imaging (EPI); which combination of parameters is clinically most efficient?
 Koji Sakai¹, Hiroshi Imai², Hiroyasu Ikeno³, Jun Tazoe¹, Masashi Yasuike¹, Hitomi Nagano¹, Himanshu Bhat⁴, and Kei Yamada¹

¹Kyoto Prefectural University of Medicine, Kyoto, Japan, ²Siemens Japan K. K., ³Kyoto Prefectural University of Medicine Hospital, ⁴Siemens Medical Solutions USA
- To find clinically feasible combinations of parameter for simultaneous multi-slice echo planar imaging (SMS-EPI) acquisition diffusion tensor imaging (DTI), we investigated the combinations of SMS factors and the amounts of inter-slice image shift to find which one can provide better signal-to-noise ratio (SNR) by two different head coils (20ch and 32ch), respectively. The SMS factors 2 and 3 with imaging shifts (>1/2) on 32ch judged clinically feasible and can be substituted on conventional DTI. The SMS factor 2 with imaging shifts 0, 1/2, 1/4 on 20ch head coil judged clinically feasible.

 Chia-Ling Chang¹, Jr-Yuan George Chiou², Ming-Long Wu^{1,3,4}, Shang-Yueh Tsai⁵, Stephan Ernst Maier^{2,6}, Bruno Madore², and Tzu-Cheng Chao^{1,4}

¹Department of Computer Science and Information Engineering, National Cheng Kung University, Tainan, Taiwan, ²Department of Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ³Institute of Applied Computer Science, Harvard University, Cambridge, MA, United States, ⁴Institute of Medical Informatics, National Cheng Kung University, Tainan, Taiwan, ⁵Graduate Institute of Applied Physics, National Cheng Chi University, Taipei, Taiwan, ⁶Department of Radiology, Sahlgrenska Academy, Gothenburg University
- A novel technique, Fast Diffusion Imaging with High Angular Resolution, is proposed to achieve whole-brain HARDI scans for clinical applications with better geometrical fidelity and shorter scan time. The present study compares tractography results and diffusion properties of each analyzed fiber tract among four-fold segmented (multi-shot) HARDI scans with different acceleration rates and a clinically used sequence with two-fold SENSE. A fully sampled four-shot HARDI scan was used as the reference. The results suggest that the novel acceleration strategy permits a four-minute scan with fairly compatible results while the clinically used method takes ten minutes.

- 3350 **Computer 20** Applied Gradient Nonlinearity Correction for Quantitative Diffusion MRI
 Baxter P Rogers¹, Allen T Newton¹, E Brian Welch¹, Jeffrey J Luci², Heidi A Edmonson³, and Bennett A Landman⁴

¹Vanderbilt University Medical Center, Nashville, TN, United States, ²University of Texas at Austin, ³Mayo Clinic, ⁴Vanderbilt University
- Accurate and reliable quantitative diffusion MRI depends on correcting for spatially varying errors in applied diffusion gradients due to nonlinearity of the gradient coil fields. We measured the temporal and inter-scanner variability of a phantom-based correction protocol on four different scanners. Estimated errors in diffusion gradient b-value and direction were significant, and differed between scanners. Scanner differences in temporal stability indicated the need for site-specific calibrations.
-
- 3351 **Computer 21** Correcting a slice distortion artifact in the multiband diffusion images
 Jiancheng Zhuang¹

¹University of Southern California, Los Angeles, CA, United States

The diffusion weighted images acquired with the multiband sequence or the Lifespan protocols shows a type of slice distortion artifact. We find that this artifact is caused by the eddy currents, which can be induced by the diffusion gradient associated with either current DW image or the previous DW images. The artifact can be corrected by further tuning the compensation circuit in the MR hardware, or by a correction algorithm which includes the diffusion gradients from the current and previous DW images.

Evaluation of diffusion directions vs averages for accurate and reproducible cardiac DTI
Darryl McClymont¹, Irvin Teh¹, Hannah Whittington¹, and Jürgen Schneider¹

¹Cardiovascular Medicine, University of Oxford, Oxford, United Kingdom

Cardiac DTI is subject to long scan times and low SNR, which invariably leads to a trade-off between the number of averages and diffusion-encoding directions to acquire. However, the exact relationship between the diffusion tensor and these parameters is unclear. In this work we utilise DTI data from five high quality ex-vivo rat hearts, and vary the SNR between 2 and 97 and the number of directions between 7 and 61. Results show that the apparent diffusion coefficient is optimised for scan time when SNR is maximised and directions are minimised, whereas parametric angle measurements are time-optimised with more directions. At typical in-vivo settings, we estimate that fractional anisotropy is being overestimated by up to 20%, while the precision of sheetlet angles may be as poor as ± 36 degrees.

Computer 23

Eddy current artifact reduction in diffusion-weighted single-refocused spin-echo EPI
Manoj Shrestha¹, Pavel Hok², Ulrike Nöth¹, and Ralf Deichmann¹

¹Brain Imaging Center (BIC), Goethe University Frankfurt, Frankfurt am Main, Germany, ²Palacky University Olomouc, University Hospital Olomouc, Czech Republic

Diffusion-weighted (DW) MRI with single-refocused spin-echo preparation suffers from eddy-current induced image distortions. In this study, a method for substantial reduction of eddy-current artifacts is proposed. Dummy scans comprising DW gradients prior to the acquisition of each multi-slice data volume yield a steady state of eddy-currents and thus comparable distortions across the volume which subsequently can be corrected via an advanced setting of the eddy-current correction FMRIB software library tool. In comparison to the commonly used twice-refocused spin-echo sequence for eddy-current compensation, the proposed method is less sensitive to radiofrequency inhomogeneities and offers higher signal-to-noise ratio due to shorter echo-time.

3354

Computer 24

Reducing Distortion in DWI Acquisitions of Prostate Scans

Roger C Grimm¹, Adam T Froemming¹, and Stephen J Riederer¹

¹Mayo Clinic, Rochester, MN, United States

Diffusion images obtained with spin echo – echo planar imaging (SE-EPI) can be acquired quickly and efficiently. In prostate applications areas of susceptibility can cause image distortion. The purpose of this work is to address these distortions with the use of multi-shot EPI techniques. A previously defined term, pseudo-gradient, is shown to be a useful analytical tool to explain and guide in the choice of acquisition parameters. Phantom and in-vivo results show the benefits of multi-shot scans to reduce distortions.

Evidence for Cross-Term Effects in Double Diffusion Encoding Experiments of Human Cortical Gray Matter
Marco Lawrenz^{1,2} and Jürgen Finsterbusch^{1,2}

¹Department of Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ²Neuroimage Nord, University Medical Centers Hamburg-Kiel-Lübeck, Hamburg-Kiel-Lübeck, Germany

Double diffusion encoding (DDE) experiments with two weighting periods applied successively in the same acquisition are a promising tool to investigate microscopic tissue properties, e.g. the cell eccentricity and the related diffusion anisotropy on a microscopic scale. Recent experiments detected the signal pattern typical for microscopic diffusion anisotropy in human cortical gray matter in vivo but were hampered by an additional signal modulation that could be related to field inhomogeneities near the skull. In this study, cross-term-compensated DDE experiments are performed to investigate the effect of field inhomogeneities on the detection of the microscopic diffusion anisotropy.

3356

On the Potential of DWI with Extrapolated High and Negative b-Values for Contrast Enhancement and Image Segmentation
Marcel Gratz^{1,2} and Harald H. Quick^{1,2}

¹Erwin L. Hahn Institute, University Duisburg-Essen, Essen, Germany, ²High Field and Hybrid MR Imaging, University Hospital Essen, Essen, Germany

A method is presented that extends the concept of calculated DWI for the generation of high tissue contrast from trace-weighted data. Using the whole range of b-values including the physically inaccessible negative b-values, image segmentation, visual hinting and ROI generation can be provided for assistance of the clinical readers. 24 patient data sets involving different pathologies were used to test the feasibility and clinical potentials of the new approach. It was found that the extrapolation to negative b-values helps to extract fluid regions, whereas internal structures of lesions and noise masking may be obtained with high b-values.

Assessing local brain morphology changes with diffusion tensor-driven tensor based morphometry (D-TBM): Application to a genetic model of dysgenesis

Elizabeth B Hutchinson^{1,2,3}, Neda Sadeghi^{1,2}, Okan Irfanoglu^{1,2,3}, Mary Whitman^{4,5}, Michelle Delisle⁶, Elizabeth Engle^{4,5,6,7,8}, and Carlo Pierpaoli^{1,2}

¹Quantitative Medical Imaging Section, NIBIB, NIH, Bethesda, MD, United States, ²SQITS/NICHD, NIH, Bethesda, MD, United States, ³Henry M. Jackson Foundation, Bethesda, MD, United States, ⁴Ophthalmology, Harvard Medical School, Boston, MA, United States, ⁵Ophthalmology, Boston Children's Hospital, Boston, MA, United States, ⁶Neurology, Boston Children's Hospital, Boston, MA, United States, ⁷Neurology, Harvard Medical School, Boston, MA, United States, ⁸Howard Hughes Medical Institute, Chevy Chase, MD, United States

Brain volume registration using diffusion tensor information faithfully matches anatomic features that are not accessible to structural registration algorithms such as white matter tracts. Thus, inspection of the deformation fields from DT-based registration using TBM (D-TBM) is advantageous for revealing local morphometric differences when compared with conventional TBM. In this study, D-TBM was used to evaluate morphometric differences and heterogeneity of abnormalities in a mouse model of dysgenesis.

Stretched-exponential model DWI as a non-invasive biomarker in grading gliomas and predicting of EGFR status

Jingjing Jiang¹ and Wenzhen Zhu¹

¹Tongji hospital, Tongji medical college, Huazhong university of science and technology, Wuhan, People's Republic of China

Stretched-exponential diffusion weighted imaging (SEM-DWI) provided a more accurate estimate than conventional DWI in grading gliomas. Moreover, SEM-DWI derived α value could effectively differentiate EGFR negative and positive group and had a significantly negative correlation with EGFR expression. Therefore, it was concluded that SEM-DWI might be applied as an effective imaging biomarker in grading gliomas and predicting of EGFR status and thus in guiding individual treatment and targeted therapy.

3359

Computer 29

Comparing the value of MRI ultra-high-b-value DWI and standard DWI in grading cerebral astrocytomas and their association with aquaporin-4

Yan Tan¹, Hui Zhang¹, Xiaochun Wang¹, and Dandan Zheng²

¹The First Hospital of Shanxi Medical University, TaiYuan, People's Republic of China, ²GE Healthcare MR Research China, People's Republic of China

Ultra-High-b-value DWI (UHBV-DWI) was shown to improve the diagnostic performance of DWI in grading gliomas. We compare the value of MRI UHBV-DWI and conventional DWI for grading astrocytomas, and to analyze the correlation of respective parameters with aquaporin (AQP) expression. We found UHBV-ADC (0.810) showed a larger area under the curve (AUC) than that of ADC (0.713) ($P < 0.05$). The ADC value showed a negative correlation with AQP4 mRNA expression ($r = -0.357$; $P = 0.024$). UHBV-ADC value positively correlated with the AQP4 mRNA expression ($r = 0.646$; $P < 0.01$). So UHBV-DWI allowed for a more accurate grading of cerebral astrocytoma as compared to DWI. UHBV-ADC may be related with the AQP4 mRNA levels.

Characterization of B0 Shim-Induced Bias in Diffusion Weighting Gradients

Yuxi Pang¹, Dariya I Malyarenko¹, Michael Schar², Lisa J Wilmes³, David Newitt³, Michael A Jacobs², and Thomas L Chenevert¹

¹Department of Radiology, University of Michigan, Ann Arbor, MI, United States, ²Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ³Department of Radiology and Biomedical Imaging, University of California San Francisco, San Francisco, CA, United States

To eliminate technical variability in quantitative diffusion imaging applications, the systematic bias in diffusion weighting gradients should be corrected. The major source of this bias is the system-specific spatial gradient non-linearity (GNL) that can be rectified using gradient design information independent of the scanned object. This study characterizes the residual sources of nonuniform diffusion weighting introduced by imperfect object-dependent B0 shimming. Using controlled de-shim gradients, we show that an imperfect shim leads to systematic offsets of the otherwise symmetric GNL profile relative to the isocenter. The empiric strategies are proposed to mitigate the shim-induced errors in ADC measurements.

Computer 31

Does artifact correction in spinal cord DTI improve sensitivity at the group level?

Gergely David^{1,2}, Patrick Freund^{1,3,4}, and Siawoosh Mohammadi^{2,4}

¹Spinal Cord Injury Center, Balgrist University Hospital, Zurich, Zurich, Switzerland, ²Department of Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ³Department of Neurophysics, Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ⁴Wellcome Trust Centre for Neuroimaging, UCL Institute of Neurology, London, United Kingdom

In this manuscript, we investigate how application of established post-processing methods (spatial registration and robust tensor fitting) and of a newly introduced outlier rejection technique referred to as reliability masking influence the statistical power of a clinical spinal cord DTI study. The assessment was performed using a previously published clinical dataset investigating microstructural correlates of spinal degeneration in cervical spondylotic myelopathy (CSM). We found that the established post-processing methods had almost no influence on the statistical power by which the microstructural differences is observed, whereas reliability masking increased the statistical power by more than 13%.

Computer 32

Investigating microstructural signatures for low-grade gliomas using Linear Multi-scale Modeling of diffusion MRI data

Barbara D. Wichtmann^{1,2}, Aapo Nummenmaa¹, Qiuyun Fan¹, Thomas Witzel¹, Elizabeth R. Gerstner³, Alexandra J. Golby^{4,5}, Sandro Santagata⁶, Bruce R. Rosen¹, Lothar Schad², Lawrence L. Wald^{1,7}, and Susie Y. Huang^{1,7}

¹A. A. Martinos Center for Biomedical Imaging, Department of Radiology, Massachusetts General Hospital, Harvard Medical School, Charlestown, MA, United States, ²Computer Assisted Clinical Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, ³Department of Neurology, Center for Neuro-Oncology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, ⁴Department of Neurosurgery, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ⁵Department of Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ⁶Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ⁷Harvard-MIT Division of Health Sciences and Technology, Massachusetts Institute of Technology, Cambridge, MA, United States

Linear Multi-scale Modeling (LMM) of diffusion MRI data is a recently developed DWI analysis technique for separating orientation distributions of restricted and hindered diffusion water compartments over a range of length scales, thereby allowing more detailed characterization of tissue microstructure. Here, we apply the LMM framework to characterize a low-grade oligodendroglioma prior to resection. We use the distinct microstructural signature of the tumor to delineate tumor extent and use results from pathology and numerical simulations to refine our understanding of the tumor microstructure.

Computer 33

Revealing the nature of microstructural correlations along axons in human brain white matter with time-dependent diffusion

Hong-Hsi Lee¹, Els Fieremans¹, and Dmitry S. Novikov¹

¹Center for Biomedical Imaging, New York University, New York, NY, United States

We explore axial diffusivity dependence on both diffusion time and gradient pulse width in major white matter tracts. This allows us to differentiate between two possible arrangements of restrictions (e.g. beads) along fibers: (1) short-range disorder, or (2) "hyperuniform" disorder (arrangement qualitatively closer to periodic). Unexpectedly, model prediction for hyperuniform disorder is more consistent with our data than for short-range disorder. If conformed histologically in human or animal studies, this would mean that restrictions along axons are not "purely" randomly distributed but rather spatially correlated – perhaps, for optimizing physiological constraints.

Longitudinal MR Imaging Study of Standard Diffusion-Weighted Imaging and NODDI in ischemic Stroke: Evolution of NODDI metrics and Correlation with Clinical Outcome

Min Tang¹, Wei Di, Xin Zhang, Jie Gao, Kaining Shi², Xiaohong Wu, and Xiaoling Zhang

¹Shaanxi Provincial People's Hospital, Xi'an, People's Republic of China, ²Clinical science, Philips Healthcare China

To observe the microstructural longitudinal alterations in neural tissues after ischemic stroke and assess the correlation with clinical outcome and NODDI metrics. 18 subjects were enrolled. Intra-cellular volume fraction(Vic) and orientation dispersion index(OD) exhibited positive correlations with NIHSS scores of patients at day 30. The correlation of the susceptibility with the NODDI metrics and prognosis is higher than the ADC values with it. NODDI may provide a more promising and reliable methods for microstructural reorganization follow-up stroke than other measures previously used in studies of stroke recovery.

Computer 35

Comprehensive analysis of the predictors of microvessel invasion in hepatocellular carcinoma: Diffusion kurtosis imaging (DKI) combined with radiological and clinical factors.

wentao wang¹, Li Yang¹, Xixing HU¹, Robert Grimm², caixia Fu³, XU Yan⁴, mengsu zeng¹, and shengxiang rao¹

¹Radiology department, zhongshan Hospital, Shanghai, People's Republic of China, ²MR Application Developmen, Siemens Healthcare, Erlangen, Germany, ³Siemens Shenzhen Magnetic Resonance Ltd, shenzhen, People's Republic of China, ⁴MR Collaboration NE Asia, Siemens Healthcare, shanghai, People's Republic of China

Diffusion Kurtosis Imaging (DKI) maps, preoperative radiological features and clinical-pathologic findings were calculated to assess their diagnostic accuracy for microvascular invasion (MVI) of hepatocellular carcinoma (HCC) in patients who were undergoing curative liver resection. Multivariate regression analysis was performed to identify independent predictive factors for MVI. The study shows that Mean Kurtosis (MK), non-smooth margin, peritumoral enhancement and incomplete radiological capsule suggest a high probability of microvessel invasion of HCC. Multivariate analysis confirmed that MK and capsule integrity show statistical significance correlation with MVI. In conclusion, MK and capsule appearance might be the predictors for MVI of primary hepatocellular carcinoma.

Computer 36

Influence of post-processing method on the repeatability of diffusion-weighted imaging parameters in healthy brain

Ashley M Stokes¹, Jack T Skinner², Laura C Bell¹, Adrienne N Dula³, Thomas E Yankeelov³, and C. Chad Quarles¹

¹Translational Bioimaging Group, Barrow Neurological Institute, Phoenix, AZ, United States, ²Imaging Programs, National Comprehensive Cancer Network (NCCN), Philadelphia, PA, United States, ³University of Texas - Austin

The purpose of this study is to investigate the influence of post-processing method on the reproducibility of brain diffusion metrics, including apparent diffusion coefficients (ADCs) and intra-voxel incoherent motion (IVIM) parameters, in healthy controls and to apply these results in a cohort of brain tumor patients undergoing treatment. ADC was highly reproducible for all methods. The IVIM diffusion and perfusion fraction showed the highest reproducibility using constrained fitting, while IVIM pseudo-diffusion showed limited reproducibility. By establishing limits of repeatability for ADC and IVIM metrics, these methods can be applied in neuropathology to determine significant changes related to treatment effects.

Computer 38

A New Fiber Orientation Distribution Function

Tom Dela Haije¹, Andrea Fuster¹, and Luc Florack¹¹Department of Mathematics and Computer Science, Eindhoven University of Technology, Eindhoven, Netherlands

In this work we introduce the barrier orientation distribution function (ODF) as an alternative to the fiber ODF that can be computed with constrained spherical deconvolution. The barrier ODF is computed directly from the data, without the need to e.g. specify a single fiber response function.

3369

Computer 39

Exploring Local White Matter Geometric Structure in diffusion MRI Using Director Field Analysis

Jian Cheng¹ and Peter J. Basser¹¹National Institutes of Health, Bethesda, MD, United States

In this abstract, inspired by microscopic theoretical treatment of phases in liquid crystals¹, we introduce a novel mathematical framework, called Director Field Analysis (DFA), to study local geometric structural information of white matter. DFA extracts some meaningful scalar indices related with the degree of orientational alignment, dispersion, and orientational distortion, from the Orientation Distribution Function (ODF) field reconstructed by Diffusion Tensor Imaging (DTI) or High Angular Resolution Diffusion Imaging (HARDI).

3370

Computer 40

Shall we use denoising in the preprocessing of diffusion weighted imaging?

Maryam Afzali¹, Hu Cheng¹, and Sharlene Newman¹¹Department of psychological and brain sciences, Indiana University, Bloomington, IN, United States

Many denoising techniques have been proposed in an attempt to remedy the low signal-to-noise ratio (SNR) of diffusion weighted images (DWI) [1-3], especially with high b values. It was shown that denoising might benefit DWI data processing such as fiber tracking [4]. However, denoising is not widely accepted as a mandatory step in the preprocessing of DWI data due to little well documented study about the effect of denoising. In this work, we tested if denoising can overcome the low SNR in tensor based diffusion analysis and fiber tracking.

3371

Diffusion - Tensor Based Morphometry (DTBM) of Normal Human Brain Development from Infancy to Adulthood

Amritha Nayak^{1,2,3}, Neda Sadeghi², M Okan Irfanoglu^{1,2,3}, and Carlo Pierpaoli^{1,2}¹Quantitative Medical Imaging Section, National Institute of Biomedical imaging and Bioengineering, Bethesda, MD, United States, ²Section for Quantitative Imaging and Tissue Sciences, Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, United States, ³Henry . M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States

During postnatal brain development brain structures undergo large changes in size, shape, composition and microstructural appearance. Diffusion tensor imaging (DTI) is an MRI modality particularly informative on white matter. We perform tensor based morphometry (TBM) using deformation fields constructed using all scalar and directional information provided by diffusion tensor data (DTBM) to measure volumetric changes of brain structures from neonate to adulthood. Our results indicate that DTBM reveals interesting patterns in the developmental trajectories for different structures in the human brain. This information would be important to characterize deviation from normal developmental patterns due to developmental delay or other disorders.

3372

Computer 42

Impact of denoising in diffusion-weighted data on spherical deconvolution modelling

Marina Racic¹, Luis Miguel Lacerda¹, Ahmad Beyh², Pedro Luque-Laguna¹, Rachel Barrett², Francisco De Santiago Requejo¹, Steven Williams¹, Gareth Barker¹, Fernando Zelaya¹, and Flavio Dell'Acqua^{1,2}¹Dept. of Neuroimaging, King's College London, London, United Kingdom, ²Dept. of Forensic and Neurodevelopmental Science, King's College London, London, United Kingdom

A well-known dilemma in DW-MRI acquisitions is to determine the extent to which signal-to-noise ratio (SNR) can be sacrificed in favour of higher spatial resolution on one hand, and in favour of shorter acquisition time on the other. In this study we quantify the reproducibility of spherical deconvolution results at 3 spatial resolutions with and without denoising, as it is still unclear how denoising methods affect the uncertainty in subsequent diffusion model fitting and whether it introduces or improves bias in modelled fibre direction.

3373

Computer 43

Density-Based Non-Rigid Registration of Diffusion-Weighted Images

Henrik Grønholdt Jensen¹, Francois Lauze¹, Mads Nielsen¹, and Sune Darkner¹

¹Computer Science, University of Copenhagen, Copenhagen, Denmark

We present a non-rigid registration method for Diffusion-Weighted MRI which uses a density and scale space approach to estimate image similarity. It allows us to employ smooth intensity-invariant similarity measures, such as Mutual Information (MI), in contrast to the model-driven registrations. Using the inherent microstructure of High Angular Resolution Diffusion Imaging (HARDI) scans, we obtain a less regularized and more flexible registration that can be used on either raw diffusion signals or reconstructions of the fiber orientations. We show some promising results on Human Connectome Project (HCP) subjects and an artificial example.

3374

Evaluating NODDI's a priori fixed parameters by combining NODDI and mcDESPT

Samira Bouyagoub¹, Charlotte L. Clarke¹, Nicholas G. Dowell¹, Tobias C. Wood^{2,3}, Hui Zhang⁴, and Mara Cercignani¹

¹Clinical Imaging Sciences Centre, Brighton and Sussex Medical School, Brighton, United Kingdom, ²Neuroimaging, IoPPN, King's College London, London, United Kingdom, ³Wellcome Trust Consortium for Neuroimmunology of Mood Disorders and Alzheimer's Disease, London, United Kingdom, ⁴Centre for Medical Image Computing, University College London, London

NODDI is a popular diffusion MRI technique that estimates indices about tissue microstructure. However it makes a priori assumptions, particularly fixing intrinsic diffusivity (DI) to be the same throughout the brain. We aim to validate this assumption by combining NODDI with mcDESPT, which enables an independent estimation of the CSF volume fraction. By doing this, we enable NODDI to estimate voxel-wise maps of DI as well as of the perpendicular diffusivity by removing the tortuosity constraint. Our estimated DI maps show that the assumed value is more suitable for white matter than gray matter and resulted in sharper contrast in neurite density maps but noisier orientation dispersion (ODI) maps. Removing the tortuosity assumption restored the ODI but degraded the quality of the neurite density map.

White matter microstructural properties are related to inter-individual differences in cognitive instability after sleep deprivation

Yuanqiang Zhu^{1,2}, Lin Liu¹, Tian Dai¹, Ziliang Xu¹, Yibin Xi², Hong Yin², and Wei Qin¹

¹Xidian, Xi'an, People's Republic of China, ²Xijing Hospital, Xi'an, People's Republic of China

tract-based spatial statistical analyses was used to investigate whether the individual differences in cognitive instability after SD was related to differences in WM structure. Resistant group exhibited significantly higher FA than vulnerable group, significant negative correlations were found between numbers of psychomotor vigilance task (PVT) lapses and FA in multiple regions. Our results also showed that 63% of individual variability in PVT lapse may be explained by variations in FA within superior longitudinal fasciculus and splenium of the corpus callosum. These findings suggested that cognitive instability after SD is closely associated with individual differences in WM integrity.

Biomarkers for fiber density: comparing Stejskal-Tanner diffusion encoding metrics with microscopic diffusion anisotropy from double-diffusion encoding imaging

Siawoosh Mohammadi^{1,2,3}, Isabel Ellerbrock¹, and Luke Edwards²

¹Department of Systems Neuroscience, Medical Center Hamburg-Eppendorf, Hamburg, Germany, ²Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ³UCL Institute of Cognitive Neurology, University College London

Different MRI biomarkers for fiber and myelin density have been proposed for MR g-ratio mapping, leaving open the question which biomarker is optimal. Here, we compare four different MRI biomarkers for fiber density using standard Stejskal-Tanner diffusion encoding to the microscopic diffusion anisotropy (MA) measured by double-diffusion encoding. Thereby, we hypothesize that a better measure of the microscopic environment shows higher (and more significant) correlations to the MA metric. Our preliminary results showed that the marker by Kaden et al. (2016) shows higher correlation to MA than NODDI, suggesting it to be a better biomarker for fiber density.

3383

Computer 53

Double Diffusion Encoding vs Single Diffusion Encoding in Parameter Estimation of Biophysical Models in Diffusion-Weighted MRI

Santiago Coelho¹, Leandro Beltrachini^{1,2,3}, Jose M. Pozo¹, and Alejandro F. Frangi¹

¹Centre for Computational Imaging & Simulation Technologies in Biomedicine (CISTIB), Department of Electronic and Electrical Engineering, The University of Sheffield, Sheffield, United Kingdom, ²School of Physics and Astronomy, Cardiff University, Cardiff, United Kingdom, ³Cardiff University Brain Research Imaging Centre (CUBRIC), Cardiff University, Cardiff, United Kingdom

Biophysical tissue models are a solid tool for obtaining specific biomarkers with diffusion MRI. However, the assumptions they rely on are sometimes inaccurate and may lead to erroneous results. Some limitations of the Neurite Orientation Dispersion and Density Imaging (NODDI) model are tackled by NODDIDA (NODDI with Diffusivities Added), at the cost of an extended acquisition protocol. Here we adapt NODDIDA to a Double Diffusion Encoding scheme to improve the parameter estimation for reduced acquisition protocols. We demonstrate through *in silico* experiments that under similar experimental conditions, this novel approach increases both the accuracy and precision of the parameter estimates.

Oscillating gradient improves the sensitivity of diffusion functional MRI

Dan Wu¹, Hanbing Lu², Yihong Yang², and Jiangyang Zhang³

¹Radiology, Johns Hopkins University School of Medicine, BALTIMORE, MD, United States, ²Neuroimaging Research Branch, National Institute on Drug Abuse, Intramural Research Program, National Institutes of Health, Baltimore, MD, United States, ³Radiology, New York University School of Medicine, NY, United States

Synopsis: Diffusion functional MRI (DfMRI) has been proposed to detect neuronal activations more directly than BOLD-fMRI, but its sensitivity to cell swelling associated with neuronal activities remains less known. Numerical simulations suggest that oscillating gradient spin echo (OGSE) diffusion MRI is more sensitive to changes in cell size than conventional pulsed gradient spin echo (PGSE) diffusion MRI. In adult rat brain DfMRI experiments with forepaw stimulation, ADC measured by OGSE showed significant reductions during stimulation, and the reductions were significantly larger than those measured by PGSE, suggesting OGSE may be more sensitive to cell swelling associated with neuronal activation than PGSE.

Effect of Realistic Timing Parameters on a Microscopic Diffusion Anisotropy Measure

Marco Lawrenz^{1,2} and Jürgen Finsterbusch^{1,2}

¹Department of Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ²Neuroimage Nord, University Medical Centers Hamburg-Kiel-Lübeck, Hamburg-Kiel-Lübeck, Germany

Double diffusion encoding experiments with two weighting periods applied successively offer access to microscopic tissue properties and can provide information complementary to diffusion tensor imaging. The MA index derived from such measurements with long mixing times, depends on the cell eccentricities, i.e. the microscopic diffusion anisotropy, and can be determined in the human brain. However, its derivation is based on ideal timing parameters, infinitely short gradient pulses and long diffusion and mixing times that cannot be gained in practice. In this study, the effect of realistic timing parameters on the MA of restricted diffusion is investigated with Monte Carlo simulations.

Quantification of pore size distributions using double diffusion encoding: assessment of the feasibility on a clinical system

Gaetan Duchene¹, Frank Peeters¹, Jorge Abarca-Quinones¹, and Thierry Duprez¹

¹Medical imaging dept, St-Luc University hospital, Université Catholique de Louvain, Brussels, Belgium

Recently, Double Diffusion Encoding (DDE) has been proposed for quantification of pore size distributions in a voxel or a Region Of Interest. Although the technique has been validated on animals with experimental MR systems, its translation to human scanners is challenging, mainly because of the limited gradient strength available on clinical systems. In this work, we present a validation of DDE on a clinical scanner on a biological phantom (asparagus). Furthermore, we restricted the acquisition time to 16 minutes which remains acceptable in clinical conditions.

In-vivo Bundle-Specific Axon Diameter Distributions Estimation across the Corpus Callosum

Muhamed Barakovic¹, David Romascano¹, Gabriel Girard¹, Maxime Descoteaux^{1,2}, Jean-Philippe Thiran^{1,3}, and Alessandro Daducci^{1,3,4}

¹Signal Processing Lab (LTS5), École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ²Sheerbrooke Connectivity Imaging Laboratory (SCIL), University of Sheerbrooke, Canada, ³University Hospital Center (CHUV) and University of Lausanne (UNIL), Switzerland, ⁴Department of Computer Science, University of Verona, Italy

Over the last decade microstructure imaging has become commonly endorsed to estimate quantitative features of neuronal tissue. However, those techniques estimate the microstructure only locally. Microstructure informed tractography was recently proposed to bolster microstructure estimates by accounting for the structure of the white matter bundles. The purpose of this study was to extend this novel technique for evaluating bundle-specific axon diameter distributions and investigate bundle-specific properties in the human brain. The experiment was performed on the MGH adult HCP dataset. The findings suggest potential application in the estimation of the axon diameter distribution along white matter bundles in whole-brain tractograms.

Phase retrieval from q-space imaging for diffusion pore imaging

Kerstin Demberg¹, Frederik Bernd Laun^{1,2}, Peter Bachert¹, Dieter Höpfel³, and Tristan Anselm Kuder¹

¹Medical Physics in Radiology, Deutsches Krebsforschungszentrum (DKFZ, German Cancer Research Center), Heidelberg, Germany, ²Institute of Radiology, University Hospital Erlangen, Erlangen, Germany, ³Electrical Engineering & Information Technology, Karlsruhe University of Applied Science, Karlsruhe, Germany

Diffusion pore imaging enables the detection of the average shape of arbitrary closed pores in an imaging volume element. Until now, an experimentally challenging phase measurement, either by measuring with a long-narrow gradient profile or by employing double diffusion encodings, was a prerequisite to obtain the full information on the Fourier transform of the pore image. In this study, we present a first experiment, where the phase information is recovered alone from the magnitude information acquired by q-space imaging. To solve this phase problem, we adopted a phase retrieval algorithm that is widely applied to X-ray diffraction data.

Comparison of diffusion propagator imaging metrics for accurate microstructure characterization in clinically acceptable scan times Luis Miguel Lacerda^{1,2}, Gareth John Barker², and Flavio Dell'Acqua²

¹Institute of Child Health, University College London, London, United Kingdom, ²Neuroimaging, King's College London, London, United Kingdom

Despite the abundance of models to describe the diffusion propagator, its usefulness has not yet been explored in a clinical/clinical research setting. In this study, we have compared global diffusion propagator imaging metrics to recently described measures of anisotropy and probability profiles at different displacement scales to characterise microstructure. Moreover, we have shown that these metrics offer complementary information to the ones currently established. Finally we have also acquired a "Reference Dataset" with several different diffusion weightings and demonstrated that by choosing the right combination, accurate reconstruction of both types of metrics is possible for clinically acceptable scan times.

3391

Validation of Sensitivity of Fast Kurtosis Measurements to Tissue Microstructural Changes Ting Gong¹, Mu Lin¹, Hongjian He¹, Qiuping Ding¹, and Jianhui Zhong¹

¹Center for Brain Imaging Science and Technology, Department of Biomedical Engineering, Zhejiang University, Hangzhou, People's Republic of China

Diffusional kurtosis imaging (DKI) is a significant extension of diffusion tensor imaging, providing sensitive biomarkers to diseases at the cost of lengthy acquisition and post-processing time. Fast DKI method operating with kurtosis tensor and based on axially symmetric approximation was then proposed to overcome the disadvantage. To explore the clinical utility of fast DKI, a Monte Carlo simulation was conducted on a tissue model to validate the sensitivity of fast kurtosis measurements to four microstructural changes. The results suggest that fast DKI method is reliable with reduced scan time but considerable sensitivity to microstructural changes frequently occurred in neurological diseases.

Computer 62

The spatial vs. angular resolution trade-off in diffusion MRI explored ex vivo at 9.4T Georgia Grisot^{1,2}, Joseph M. Mandeville², and Anastasia Yendiki²

¹Harvard-MIT Health Sciences and Technology, Massachusetts Institute of Technology, Cambridge, MA, United States, ²Athinoula A. Martinos Center for Biomedical Imaging, MGH, Charlestown, MA, United States

The time constraints of in vivo diffusion MRI require a compromise to be made between spatial and angular resolution. Given the lack of ground truth on the configuration of human brain connections, determining the optimal operating point along this trade-off is still an open problem. We use high-SNR ex vivo human data at microscopic resolution to study the effect of spatial and angular resolution on dMRI tractography accuracy. Our findings show that voxel size has a much more dramatic effect on tractography reconstruction of challenging white matter configurations than the number of gradient directions.

Rat brain development assessed by high-field neurite orientation dispersion and density imaging

Nicolas Kunz¹, Stéphane V Sizonenko², Rolf Gruetter^{1,3}, Petra S Hüppi², and Yohan van de Looy^{1,2}

¹Laboratoire d'imagerie fonctionnelle et métabolique, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ²Département développement et croissance, Université de Genève, Geneva, Switzerland, ³Département de radiologie, Geneva and Lausanne, Switzerland

Diffusion tensor imaging (DTI) has been widely used to study rodent brain development. Nevertheless, the parameters derived from DTI are sensitive to, but non-specific to, the tissue's microstructure. Recently, NODDI (neurite orientation dispersion and density imaging) has been proposed. We aimed to estimate the real input of NODDI derived parameters in rodent brain development. ODI appears more accurate and specific to reflect GM (increase with dendritic arborization) and WM (decrease with myelination) development than FA and could be a very important parameter in the assessment of perinatal brain injuries. Conclusion about the other NODDI estimates requires further experiments.

3396

Computer 66

Disentangling myelination and axonal density using NODDI and mcDESPOT – a multimodal microstructure imaging approach

Samira Bouyagoub¹, Nicholas G. Dowell¹, Charlotte L. Clarke¹, Tobias C. Wood^{2,3}, Hui Zhang⁴, and Mara Cercignani¹

¹Clinical Imaging Sciences Centre, Brighton and Sussex Medical School, Brighton, United Kingdom, ²Neuroimaging, IoPPN, King's College London, London, United Kingdom, ³Wellcome Trust Consortium for Neuroimmunology of Mood Disorders and Alzheimer's Disease, London, United Kingdom, ⁴Centre for Medical Image Computing, University College London, London, United Kingdom

There is an increasing demand for specific tissue microstructure markers that can be related to demyelination and axonal loss. Quantitative MRI techniques are sensitive to microscopic changes but tend to be non-specific. We propose to combine NODDI, a popular MRI diffusion technique, with mcDESPOT, a multi-component relaxation analysis technique, to obtain separate estimates of the volumes of myelin, extra-cellular and intra-cellular spaces. This multimodal MR approach opens the possibility to disentangle changes to myelination and axonal density with the exciting prospect of achieving *in vivo* histology.

Computer 67

Negentropy: non-Gaussian characterization for Diffusion Spectrum Imaging

Gabriel Varela-Mattatall¹, Alexandra Tobisch^{2,3}, Rüdiger Stirnberg², Steren Chabert⁴, Tony Stöcker^{2,3}, Cristian Tejos^{1,5}, and Pablo Irarrazaval^{1,5}

¹Biomedical Imaging Center, Santiago, Chile, ²German Center of Neurodegenerative Diseases (DZNE), Bonn, Germany, ³University of Bonn, Bonn, Germany, ⁴Department of Biomedical Engineering, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile, ⁵Department of Electrical Engineering, Pontificia Universidad Católica de Chile, Santiago, Chile

Measuring non-Gaussianity in the diffusion signal has revealed new possibilities for discovering new biomarkers for clinical applications. Therefore, it results desirable to incorporate and quantify the non-Gaussian trait of the diffusion propagator in Diffusion Spectrum Imaging. Unfortunately, the established index known as Kurtosis is sensitive to noise, making it unfeasible to obtain from the noisier, but higher resolution propagator. In this work, we propose an alternative index known as Negentropy. We demonstrate from noisy simulations and *in-vivo* DSI data the robustness of the Negentropy index against Kurtosis.

3398

Computer 68

Detection of distinct tract-specific axon diameter and density estimates in the *in vivo* human brain using TractCaliber MRI

Susie Y Huang¹, Thomas Witzel¹, Qiuyun Fan¹, Barbara Wichtmann², Aapo Nummenmaa¹, Lawrence L Wald¹, and Eric Klawiter³

¹Athinoula A. Martinos Center for Biomedical Imaging, Department of Radiology, Massachusetts General Hospital, Harvard Medical School, Charlestown, MA, United States, ²Computer Assisted Clinical Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany, ³Department of Neurology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States

In this work, we apply the TractCaliber approach to a group of healthy subjects and show that distinct tract-specific estimates of axon diameter may be obtained in different white matter tracts in the normal human brain. Larger diameter axons are consistently estimated in the corticospinal tracts and are shown to be distinct from those in the cingulum, an adjacent and orthogonal white matter tract. The development of robust tract-specific axon diameter-weighted maps may be useful for refining existing tractography algorithms.

A unified signal readout for reproducible multimodal characterisation of brain microstructure

Francesco Grussu¹, Marco Battiston¹, Ferran Prados^{1,2}, Torben Schneider^{1,3}, Enrico Kaden⁴, Sébastien Ourselin², Rebecca S. Samson¹, Daniel C. Alexander⁴, and Claudia A. M. Gandini Wheeler-Kingshott^{1,5,6}

¹UCL Institute of Neurology, Queen Square MS Centre, University College London, London, United Kingdom, ²Translational Imaging Group, Centre for Medical Image Computing, Department of Medical Physics and Biomedical Engineering, University College London, London, United Kingdom, ³Philips UK, Guildford, Surrey, United Kingdom, ⁴Centre for Medical Image Computing, Department of Computer Science, University College London, London, United Kingdom, ⁵Department of Brain and Behavioural Sciences, University of Pavia, Pavia, Italy, ⁶Brain MRI 3T Mondino Research Center, C. Mondino National Neurological Institute, Pavia, Italy

Multimodal imaging is very promising for characterising brain microstructure *in vivo*, but it is usually performed employing a variety of signal readouts, which disrupts the spatial correspondence of the multimodal features. Here we demonstrate a multimodal imaging protocol for detailed characterisation of brain microstructure with unified single-shot EPI readout. Our aim is to provide macromolecular volume via inversion recovery spin echo, neurite morphology via diffusion imaging in close spatial alignment and thus to combine those for estimating myelin g-ratio. We show that our protocol enables the evaluation of parametric maps with high reproducibility that capture biological differences among healthy subjects.

¹Department of Anatomy, Donders Institute for Brain, Cognition & Behaviour, Radboud University Medical Center, Nijmegen, Netherlands, ²Department of Neurosurgery, Radboud University Medical Center, Nijmegen, Netherlands, ³Oxford Centre for Functional MRI of the Brain, University of Oxford, United Kingdom, ⁴Faculty of Medical Sciences, Radboud University, Nijmegen, Netherlands, ⁵Department of Anesthesiology, Pain and Palliative Care, Radboud University Medical Center, Nijmegen, Netherlands

To optimize neuromodulation therapy of orofacial pain, a more profound insight in the trigeminal pathways in the human brainstem is of crucial importance. Using ex-vivo, 11.7T magnetic resonance imaging, polarized light microscopy and myelin staining methods, both the ventral and dorsal trigeminothalamic tracts can be visualized in humans. The combination of these visualization techniques strengthens the validity of these findings although the number of specimens forms a limitation. Future research must show whether these results are reproducible in more human brains and whether the described tracts could lead to new neuromodulation targets for the treatment of orofacial pain.

Orientation-invariant and non-parametric Axon Diameter Distribution mapping using PGSE and regularized discrete linear modeling

David Romascano¹, Muhamed Barakovic¹, Anna Auria¹, Tim Bjørn Dyrby^{2,3}, Jean-Philippe Thiran^{1,4}, and Alessandro Daducci^{1,4,5}

¹Signal Processing Laboratory 5 (LTS5), EPFL, Lausanne, Switzerland, ²Danish Research Centre for Magnetic Resonance, Center for Functional and Diagnostic Imaging and Research, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark, ³Department of Applied Mathematics and Computer Science, Technical University of Denmark, Lyngby, Denmark, ⁴University Hospital Center (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland, ⁵Computer Science department, University of Verona, Italy

Axon diameter distributions (ADDs) change during brain development and are altered in several brain pathologies. Mapping ADDs non-invasively using dMRI could provide a useful biomarker, but existing methods are either parametric, orientation-dependent, summarize the whole ADD as a single measure or use non-standard protocols. We propose to estimate the ADD from an orientation-invariant PGSE protocol optimized for axon diameter sensitivity, using a discrete linear model with smoothness and sparsity regularization. To our knowledge, we are the first to show that PGSE sequences can be used to extract orientationally invariant and non-parametric ADD estimates.

Diffusion-Weighted Split-Echo RARE Imaging Free Of Geometric Distortion for Renal MRI at Ultrahigh Fields

Joao Periquito¹, Katharina Paul¹, Till Huelnhagen¹, Yiyi Ji¹, Min-Chi Ku¹, Kathleen Cantow², Erdmann Seeliger², Bert Flemming², Dirk Grosenick³, Andreas Pohlmann¹, and Thoralf Niendorf^{1,4}

¹Berlin Ultrahigh Field Facility (B.U.F.F.), Max Delbrueck Center for Molecular Medicine, Berlin, Germany, ²Institut für Vegetative Physiologie, Charité - Universitätsmedizin Berlin, Berlin, Germany, ³Physikalisch-Technische Bundesanstalt (PTB), Berlin, Germany, ⁴Experimental and Clinical Research Center (ECRC), a joint cooperation between the Charité Medical Faculty and the Max Delbrueck Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany

T_2^* mapping does not fully represent renal tissue oxygenation. Diffusion-weighted imaging (DWI) can provide information about confounding factors, which can be used to correct T_2^* . The most widely used DWI technique SE-EPI is sensitive to magnetic field inhomogeneities and hence prone to geometric distortions. In this work we propose a diffusion-weighted Rapid Acquisition Refocusing Enhancement (RARE) variant for DWI of the rat kidney free of geometric distortions. Phantom experiments validated the diffusion weighting implementation in the common RARE sequence. Ex-vivo and in-vivo experiments using diffusion-weighted RARE showed no geometric distortions at 9.4 Tesla.

Improved algorithm for navigator-based free breathing cardiac diffusion tensor imaging
Fang Dong¹ and Shi Cheng¹

¹Siemens Shenzhen Magnetic Resonance Ltd., ShenZhen, People's Republic of China

Cardiac diffusion tensor imaging is an effective way to depict the fiber structure of the myocardium. A navigator(NAV)-based stimulated-echo (STEAM) method was proposed by Nielles-Vallespin to obtain cDTI in vivo. However, its use of a biofeedback process where the subjects had to adapt their breathing pattern in real-time can hinder its clinical implementation. In this abstract, we optimized the NAV accept/reject algorithm, using which the scanning efficiency and the image SNR were both largely improved. Therefore, our work laid a great foundation for the clinical use of free breathing cDTI in the future.

Application of diffusion kurtosis MR imaging in characterization of renal cell carcinomas with different pathological types and grades
Jie Zhu¹, Ying Sa Li¹, Jie Xiao Luo¹, Dan Dan Zheng², and Min Chen¹

¹Beijing Hospital, Beijing, People's Republic of China, ²GE healthcare, MR research China, People's Republic of China

Identification of subtypes and pathological grades of renal cell carcinoma (RCC) prior to treatment has clinical significance in determining a treatment strategy and evaluating prognosis. In our research, we detected microstructural differences of RCC by using diffusion kurtosis imaging (DKI). The results showed that DKI had good inter- and intra-observer reproducibility of RCC as a new reliable noninvasive biomarker. Kurtosis metrics showed statistical differences between RCC and contralateral renal parenchyma, among the subtypes of RCC, and between low- and high-grade clear cell RCCs. Thus, DKI has the potential application in depicting the microstructural characteristics of RCC.

Origin of diffusion anisotropy in human kidney: a combined DTI and IVM study
Sophie van Baalen¹, Bart Vroiling¹, Martijn Froeling², and Bennie ten Haken¹

¹Faculty of Science and Technology, University of Twente, Enschede, Netherlands, ²Radiology, University Medical Centre Utrecht, Utrecht, Netherlands

To visualize the anisotropy of diffusion and pseudodiffusion, we have performed a two-tensor fit (\mathbf{D} and \mathbf{D}^*) on IVIM data in healthy volunteers. We have performed tractography on both tensors and compared the results with tractography performed using a conventional DTI tensor fit. Tracking was possible using both \mathbf{D} and the \mathbf{D}^* derived tensors and resulted in patterns similar to conventional tractography. We conclude that diffusion and pseudodiffusion both have an anisotropic component that can be visualized using tractography, which indicates that they both likely contribute to the coherent diffusion anisotropy that is detected in conventional monoexponential DTI.

3407

Computer 77

ICA based filtering of IVIM-DWI data to improve fidelity of parametric diffusion maps in breast cancer patients

Dattesh D Shanbhag¹, Tetsuya Wakayama², Reem Bedair³, Andrew J Patterson⁴, Fiona J Gilbert³, Rakesh Mullick¹, and Martin J Graves^{3,4}

¹GE Global Research, Bangalore, India, ²GE Healthcare, Hino, Japan, ³Department of Radiology, University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom, ⁴Department of Radiology, Addenbrookes Hospital, Cambridge, United Kingdom

IVIM-DWI data can be potentially corrupted by eddy currents, susceptibility artifacts, motion and image reconstruction methods. We hypothesized that artifacts in IVIM imaging could be separated from true diffusion decay using an independent component analysis (ICA) methodology. In this work, we demonstrate that with ICA based filtering of raw IVIM data, transients in IVIM data are removed, with consequent improvement in IVIM model fit quality and reduction in saturated values in pseudo-diffusion \mathbf{D}^* maps. This should therefore improve confidence in interpreting IVIM parametric maps in clinical practice.

A multi-directional methodology for discriminating benign from malignant lesions on DWI for women with dense breasts

Alan Penn¹, Barry Reich¹, Etta Pisano², Vandana Djalani³, Elodia Cole², David Brousseau⁴, Milica Medved⁵, Gregory S. Karczmar⁶, Guimin Gao⁵, and Hiroyuki Abe⁶

¹Alan Penn & Assoc., Inc., Rockville, MD, United States, ²Beth Israel Deaconess Medical Center, ³Radiology, Beth Israel Deaconess Medical Center, ⁴California Hospital Medical Center, ⁵University of Chicago, ⁶Radiology, University of Chicago

We describe a new methodology for discriminating benign from malignant breast lesions on DWI for women with dense breasts and show that the new methodology results in statistically significant improvement over standard ADC methods. The methodology uses computer models that can be constructed independently from the three directional DWI signals or from the trace signal. Preliminary results show improved discrimination is obtained using the multi-directional models when compared to using the trace. The methodology can be adapted for computer-aided-detection by tiling the image, independently marking each tile with areas of suspicion, and constructing a mosaic from the marked tiles.

Optimization of Intra-voxel Incoherent Motion Measurement in Diffusion-Weighted Imaging of Breast Cancer

Wengjing Chen¹, Juan Zhang², Dan Long², Zhenchang Wang³, and Jianming Zhu¹

¹Biomedical Engineering, China Jiliang University, Hangzhou, People's Republic of China, ²Radiology, Zhejiang Cancer Hospital, Hangzhou, People's Republic of China, ³Radiology, Beijing Friendship Hospital, Beijing, People's Republic of China

The purpose was to use intra-voxel incoherent motion (IVIM) measurement in DWI to distinguish benign from malignant breast tissues. IVIM-derived parameter maps \mathbf{D} , \mathbf{f} , and \mathbf{D}^* were computed using segmented fitting method with proper threshold b -value. The region of interests were avoided the area of calcification. With pathological diagnosis as the gold standard, receiver operating characteristic (ROC) curves for three parameters and $\mathbf{f} \times \mathbf{D}^*$ reflect that the area under the curve (AUC) of \mathbf{D} and $\mathbf{f} \times \mathbf{D}^*$ are 0.862 and 0.726, respectively. It suggested that these two parameters have high significance for the diagnosis of breast cancer lesions.

- Diffusion-weighted (DW) MRI of the prostate has increased the diagnostic accuracy for the detection of prostate cancer. However, acquisition time of DWI is still relatively long. Therefore, we evaluated the feasibility of simultaneous multi-slice (SMS) DWI for accelerated MRI of the prostate. Qualitative and quantitative image analyses in phantom, volunteer and patient measurements revealed similar image quality for DWI_{SMS} as compared to standard DWI sequences. Thus, DWI_{SMS} seems feasible for clinical routine in order to optimize patient throughput and economic efficiency, which is desirable, due to the recent implementation of prostate MRI into clinical guidelines and the expected increase in patient numbers.

Region	TE (ms)	ADC (mm ² /s)	D (mm ² /s)	f (%)	Dstar (mm ² /s)
Peripheral Zone	100	1.2	1.1	10	0.1
	200	1.1	1.0	10	0.1
	300	1.0	0.9	10	0.1
Central Zone	100	1.5	1.4	10	0.1
	200	1.4	1.3	10	0.1
	300	1.3	1.2	10	0.1

¹Department of Radiology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, People's Republic of China, ²MR Collaboration NE Asia, Siemens Healthcare, Shanghai, People's Republic of China

We performed multi-b value and multi-TE diffusion imaging with two repetition on healthy human prostate to evaluate the influence of TE on reproducibility and quantification of IVIM diffusion model. The result showed that the Dstar and f parameters of IVIM model had high CVs and particularly high variability, while conventional ADC and D showed high reproducibility and a moderate TE-dependency in the peripheral zone and mild TE-dependency in the central zone. This work suggests that using diffusion parameters as quantitative biomarkers should consider the reproducibility and TE-dependency in clinical studies.

Relationship between diffusion kurtosis imaging and RSI: application to prostate cancer

Roshan Karunamuni¹, Joshua Kuperman¹, Tyler Seibert¹, Natalie Schenker¹, Rebecca Rakow-Penner¹, Jose Teruel Antolin¹, Pal Erik Goa², David Karow¹, Anders Dale¹, and Nathan White¹

¹University of California San Diego, San Diego, CA, United States, ²NTNU, Trondheim, Norway

This study explored the relationship between restriction spectrum imaging (RSI) and diffusion kurtosis imaging. Regions of interest for suspicious lesions and background tissue were identified in four patients with PIRADS 5 lesions. Kurtosis was estimated using either the signal fractions obtained from the RSI fit or the cumulant expansion for the NMR diffusion signal. A strong relationship was observed between RSI-derived restricted signal fraction and RSI-derived kurtosis. The performance of these two metrics was comparable in discriminating between suspicious lesions and background prostate tissue, and both outperformed the cumulant expansion approximation to kurtosis.

Computer 87

Detection of peripheral zone prostate cancer using diffusion-weighted intravoxel incoherent motion imaging

Jin Shang¹, Hui Zhang¹, Miaoling Li¹, Jian Yang¹, and Rong Wang^{1*}

¹Department of radiology, the first affiliated hospital of medical college, Xi'an Jiaotong University, Xi'an, People's Republic of China

DWI has been proven to improve prostate cancer detection, and it reflects and measures the diffusion of water molecules within biological tissues due to thermal Brownian motion. However, to improve the significance of DWI, it is necessary to evaluate separately the two components of diffusion: the puremolecular diffusion and the perfusion-related diffusion originating from capillary microcirculation. IVIM-DWI, applying a bi-exponential fitting function, allows the extraction of pure molecular diffusion parameters (D) and perfusion-related diffusion parameters (D* and f). Therefore, the aim of this study is to further characterize and compare the biexponential nature of the diffusion related signal decay with multiple b-factors for PZ PCa and healthy PZ areas.

Computer 88

Application of Fast SE-EPI-based T2 Mapping in Prostate, with Comparison to Conventional CPMG-Based T2 Mapping

Xu Yan¹, Zan Ke², Minxiong Zhou³, Caixia Fu⁴, Xiangde Min², and Liang Wang²

¹MR Collaboration NE Asia, Siemens Healthcare, Shanghai, People's Republic of China, ²Department of Radiology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, People's Republic of China, ³Shanghai University of Medicine & Health Sciences, Shanghai, People's Republic of China, ⁴Siemens Shenzhen Magnetic Resonance Ltd., Shenzhen, People's Republic of China

This study compared a fast SE-EPI-based T2 mapping method with a conventional CPMG-based method. The SE-EPI method is based on multi-TE data and can be integrated into a diffusion sequence with very fast acquisition speed (around 30 s). The voxel-by-voxel and region of interest (ROI)-based comparisons were performed using two methods, which showed that their T2 maps have a strong correlation. In addition, the clinical validation showed that the T2 maps of the two methods have similar statistical significance and can be used to differentiate between prostate cancer (PCa) and benign prostatic hyperplasia (BPH). This work suggests that the SE-EPI-based method is a quick quantification method, and could be used or combined with diffusion and other quantification methods for multi-parametric analysis. In addition, it may also have potential applications in body regions which are susceptible to motion artifacts.

The ADC characteristics of the bone marrow within different anatomical parts: a DWI MR based study

mi Yang¹, xiaodong Ji², Zhizheng Zhuo, and shuang Xia

¹Department of Radiology, Tianjin first center hospital, Tianjin, People's Republic of China, ²Department of Radiology

The diffusion weighted imaging has been widely used in clinical disease diagnosis, and the ADC value plays a key role in this progress. At present, the ADC values of normal organs and tissues have been reported, but few studies have been done on ADC values of normal bone marrow within different anatomical parts. In this study, the ADC values within different anatomical parts of bone marrow were measured and analyzed by using WB-DWI (whole body diffusion weighted imaging). And we furtherly evaluated the relationship of these ADC values with age and gender.

Computer 91

Simultaneous multislice diffusion weighted imaging in whole-body PET/MRI for accelerated multiparametric staging of oncologic patients. Ferdinand Seith¹, Jana Taron¹, Christina Pfannenbergl¹, Konstantin Nikolaou¹, Christina Schraml¹, and Petros Martirosian²

¹Department of Diagnostic and Interventional Radiology, Eberhard-Karls-University Tuebingen, Germany, Tuebingen, Germany, ²Section on Experimental Radiology, Eberhard-Karls-University Tuebingen, Germany, Tuebingen, Germany

Simultaneous multislice diffusion weighted imaging (SMS-DWI) is a promising technique to shorten scan time in MRI. Aim of our study was to compare the diagnostic performance of SMS-DWI to conventional DWI for multiparametric whole-body examinations of oncologic patients in PET/MRI. We performed an evaluation in three steps: First in a phantom study, second in a volunteer study and third in a patient study with 20 oncologic patients. We found that SMS-DWI led to a significant reduction of scan time and, although suffering from slightly impaired image quality, provided reliable ADC values and lesion conspicuity of PET positive lesions.

Computer 92

Use of texture analysis of intravoxel incoherent motion (IVIM) in evaluating the expression of Ki67 of hepatitis B virus-related hepatocellular carcinoma (HCC)

Qungang Shan¹, Jingbiao Chen¹, Ronghua Yan¹, Yao Zhang¹, Hao Yang¹, Xin Li², Zhongping Zhang³, Yunhong Shu⁴, Churong Lin, Tianhui Zhang¹, Bingjun He¹, Zhuang Kang¹, Xi Long¹, and Jin Wang¹

¹Department of Radiology, the Third Affiliated Hospital, Sun Yat-sen University (SYSU), Guangzhou, People's Republic of China, ²GE Healthcare MR Research China, Guangzhou, People's Republic of China, ³MR Research China, GE Healthcare, Beijing, ⁴Mayo Clinic

HCC is the second cause of cancer-related deaths and most HCC patients are accompanied with hepatitis B virus-related cirrhosis in China. Ki67 is a protein reflecting the proliferative activity of HCC and could be used as a predictor of prognosis. We assessed the value of the texture parameters in evaluating the expression of Ki67 of HBV-related HCCs by whole tumor analysis. Our results showed that Dclusterprominence showed best diagnostic performance among all texture parameters. ADC and IVIM derived texture parameters might be used as useful and noninvasive biomarkers for evaluating the expression of Ki67 of HBV-related HCCs.

Feasibility of diffusion kurtosis imaging as a tool for differentiation between benign and malignant uterine lesions

Yoshihiko Fukukura¹, Yuichi Kumagae¹, Masanoari Nakajo¹, Kiyohisa Kamimura¹, Aya Umanodan¹, Takashi Iwanaga², Tomoyuki Okuaki³, and Takashi Yoshiura¹

¹Radiology, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan, ²Radiological Technology, Kagoshima University Hospital, Kagoshima, Japan, ³Philips Electronics Japan, TN, Japan

This study focused on the feasibility of DKI for differentiating benign from malignant uterine lesions. The ADC and D of malignant tumor (MT) were significantly lower than those of endometrial hyperplasia (EH) ($p=0.005$ and 0.004), uterine fibroid (UF) (both, $p<0.001$), normal endometrium (NE) (both, $p<0.001$), and normal myometrium (NM) (both, $p<0.001$), which indicative of the increased cellularity within uterine malignant tumor that resulted in restricted water diffusion. K was significantly higher in MT than in EH ($p=0.003$), UF ($p<0.001$), NE ($p<0.001$), and NM ($p<0.001$), possibly representing complexity of tissue microstructure in MT compared to benign lesions. DKI enables differentiate benign from malignant uterine lesions.

Computer 94

Zero-TE computed Diffusion Weighted Imaging Technique for the abdomen

Hiroshi Kusahara¹, Yuki Takai¹, and Yoshimori Kassai¹

¹MRI Systems Development Department, Toshiba Medical Systems Corporation, Tochigi, Japan

In this study is to adapt the short-TE cDWI (sTE-cDWI) technique, including the "Zero-TE", validated previously in the brain⁴ to the abdominal region. The algorithm under evaluation allows computing diffusion images for arbitrary combinations of TE and b-value based on three acquisitions (3-points method). With this method we demonstrate it is possible to suppress T2 shine-through effects and as well as improve the signal-to-noise and contrast-to-noise ratios of tissues with short T2 and low ADC. The clinical benefits of the method and the preliminary results on volunteers are discussed.

3425

Computer 95

Comparison between IVIM combined with fuzzy clustering algorithm and IVIM combined with Bayesian method in the thyroid cancer

Kaining Shi¹, Fengmao Chiu², Yunlong Yue³, Lee Jiang⁴, Lili Zuo³, and Yanfang Jin³

¹Philips Healthcare (China), Beijing, People's Republic of China, ²Philips Healthcare, Taipei, Taiwan, ³Department of MR, Beijing Shijitan hospital of capital medical university, Beijing, People's Republic of China, ⁴Philips Healthcare (China), Suzhou, People's Republic of China

To improve the stability of the nonlinear curve fitting of IVIM, the Fussy clustering technique (FCM) and data driven Bayesian approach are combined with IVIM in the imaging of thyroid tumors. Both FCM and Bayesian approach can improve the homogeneity of IVIM parameters. With limited sample size, FCM has similar diagnosis efficiency with conventional method using less calculation time, while Bayesian approach doesn't increase the diagnosis efficiency.

Computer 96

Evaluation of the reduced field-of-view Diffusion Weighted Imaging for staging of endometrial adenocarcinoma

Hiroki Hori^{1,2}, Toshio Yamaguchi³, Hisashi Yoshihara¹, Youko Murakami¹, Yoshiyuki Konishi², Yoshihiro Muragaki^{2,4}, Jinichi Sasanuma⁵, and Kazuo Watanabe⁵

¹Radiology, Shin-Yurigaoka General Hospital, Kanagawa, Japan, ²Faculty of Advanced Techno-Surgery (FATS), Institute of Advanced Biomedical Engineering and Science, Tokyo Women's Medical University, Tokyo, Japan, ³Research Institute for Medical Imaging, Shin-Yurigaoka General Hospital, Kanagawa, Japan, ⁴Neurosurgery, Tokyo Women's Medical University, Tokyo, Japan, ⁵Neurosurgery, Shin-Yurigaoka General Hospital, Kanagawa, Japan

The objective of this retrospective study is to evaluate the differences of the accuracy in endometrial adenocarcinoma using FOCUS DWI compared to that using conventional SS-EPI DWI. We calculated the accuracy by the interpretation of magnetic resonance (MR) imaging and the pathology. The accuracy in the FOCUS DWI was significantly better than that in the SS-EPI DWI. This may be due to the decrease of distortion in DWI, which induced the artifacts. There was improvement of the accuracy using the FOCUS DWI in the patient who had suspected endometrial adenocarcinoma.

In this study, we used MR-based estimation of abdominal fat distribution and the degree of adipocyte hypertrophy to study sex and ethnic differences in 4.5-year-old Asian children. Our results show sexual dimorphism in abdominal fat distribution in preschool children. Girls had higher subcutaneous fat depot volumes and lower adipose tissue hydration than boys. We also found that at 4.5 years, both deep and superficial subcutaneous fat volumes in Indian children were higher, while the ethnic difference in internal fat was non-significant. These differences may help explain why Indians are more susceptible to metabolic and cardiovascular diseases.

A large intramyocellular lipid (IMCL) pool is associated with early pathogenesis of insulin resistance and type 2 diabetes. Studies from mother-offspring cohorts indicate that, like obesity and metabolic traits, IMCL is also highly heritable. However, there have been not many studies on the effect of genetic variation on IMCL. Although a number of genome-wide association studies (GWAS) have established associations between several genetic loci and metabolic disorders, it is not yet known if these loci also contribute to IMCL levels, and help explain ethnic difference in IMCL levels. In this study, we examined the ethnic differences (Indian, Malay and Chinese) in IMCL in Singaporean children and the genetic risk variant(s) associated with these differences.

Determination of Droplet Size Distribution in Brown Adipose Tissues by Diffusion NMR Spectroscopy

Sanjay Kumar Verma¹, Jadegoud Yaligar¹, Navin Michael², Tian Xianfeng¹, Venkatesh Gopalan¹, Suresh Anand Sadananthan², Rengaraj Ananthraj¹, and S. Sendhil Velan^{1,2}

¹Laboratory of Molecular Imaging, Singapore Biomed Imaging Consortium, Singapore, Singapore, ²Singapore Institute for Clinical Sciences, Singapore

Non-Invasive Imaging of Brown Adipose Tissue is of significant interest due to its potential to combat obesity and diabetes. In this study, we have utilized diffusion spectroscopy to estimate the droplet size distribution in chow and high-fat diet fed brown adipose tissues obtained from rodents. The high-fat diet BAT exhibited reduction in the restriction due to the increase in droplet size. The histology results confirm the droplet size distribution in both control and high-fat diet tissues.

¹Department of Diagnostic and Interventional Radiology, Technical University of Munich, Munich, Germany, ²Else Kröner Fresenius Center for Nutritional Medicine, Technical University of Munich, Munich, Germany, ³Philips Research Laboratory, Hamburg, Germany

Proton density fat fraction (PDFF) mapping has been emerging as important metabolic phenotyping parameter in obesity enabling spatially-resolved fat quantification in multiple organs. PDFF of adipose tissue has also recently gained significant attention due to the interest in developing biomarkers of brown fat which is assumed to be present in the adult supraclavicular fossa. However, it remains unknown how adipose tissue PDFF relates to other fat depots and anthropometric parameters. The present study aims to investigate the relationship of the supraclavicular and gluteal fat PDFF with SAT and VAT volumes and anthropometric obesity markers.

¹The 4th center hospital of TianJin, Tianjin, People's Republic of China, ²Inner Mongolia people's hospital, Inner Mongolia, People's Republic of China, ³Philips Healthcare, Beijing, People's Republic of China

Till now the type 2 diabetes (T2DM) is more and more prevalent, and diabetic nephropathy (DN) has become the main leading cause of end-stage renal disease (ESRD). However the onset of DN is always ambiguous. In recent years, many studies focused on the change of renal oxygenation in diabetes and showed renal hypoxia especially in medulla. Blood oxygen level dependent magnetic resonance imaging (BOLD-MRI) is a non-invasive method that can assess hypoxia in prostate gland by utilizing the endogenous contrast generated by paramagnetic deoxyhemoglobin.

¹Department of Radiology, Institution of Surgical Sciences, Uppsala University, Uppsala, Sweden, ²Department of Pediatrics, the Institution of Clinical Sciences, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, ³Department of Pediatrics, Halmstad Hospital, Halmstad, Sweden, ⁴Applied Science Laboratory, GE Healthcare, Uppsala, Sweden, ⁵Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, ⁶Department of Pediatric Radiology, The Sahlgrenska University Hospital, Gothenburg, Sweden, ⁷Antaros Medical, Mölndal, Sweden

The purpose of this study was to characterize and compare brown and white adipose tissue in 7 year-old overweight/obese and normal weight children using whole-body water-fat MRI. Correlations were also performed between the brown adipose tissue measurements and other measurements, such as VAT and SAT volumes. Results overall showed expected differences and associations to several measures relevant for obesity. We conclude that whole-body water-fat MRI of 7 year-old children is feasible and allows characterization of brown and white adipose tissue.

Receiver operating characteristic analysis of fat fraction reveals no universal cut-off to reliably identify in vivo brown adipose tissue in adult humans

Terence Jones^{1,2}, Sarah Wayte³, Narendra Reddy⁴, Oludolapo Adesanya¹, Thomas Barber^{2,4}, and Charles Edward Hutchinson^{1,2}

¹Department of Radiology, University Hospitals Coventry & Warwickshire NHS Trust, Birmingham, United Kingdom, ²Warwick Medical School, University of Warwick, Coventry, United Kingdom, ³Medical Physics, University Hospitals Coventry & Warwickshire NHS Trust, Coventry, United Kingdom, ⁴Department of Endocrinology, University Hospitals Coventry & Warwickshire NHS Trust, Birmingham, United Kingdom

Lower fat content within brown adipose tissue (BAT) compared to white adipose tissue (WAT) has been exploited using Dixon-based MRI imaging methods to visualize BAT but is subject to inter-rater variability. To determine the optimal fat fraction threshold for identifying BAT, receiver operating characteristic (ROC) analyses of fat fraction maps derived from 3 point IDEAL MRI scans were performed for sixteen subjects.

This method had good-to-excellent accuracy in four cases, and fair accuracy in two, but failed in ten. A single universal cut-off point to differentiate BAT and WAT could not be identified, instead the optimal thresholds varied between individuals.

3438

Computer 108

Adipose tissue and ectopic fat responses to an extended fast in healthy male adults

Alison Sleigh^{1,2}, Ajay Thankamony³, Albert Kouzman⁴, Vlada Bokii¹, Graham J Kemp⁵, Leanne Hodson⁶, and David B Dunger³

¹Wolfson Brain Imaging Centre, University of Cambridge, Cambridge, United Kingdom, ²NIHR/WT Clinical Research Facility, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, ³Department of Paediatrics, University of Cambridge, Cambridge, United Kingdom, ⁴MRC Human Nutrition Research, Cambridge, United Kingdom, ⁵Department of Musculoskeletal Biology, University of Liverpool, Liverpool, United Kingdom, ⁶Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, United Kingdom

We have investigated the response of different fat deposits to a 28 h fast in healthy nonobese males and shown significant increases in CH₂ IMCL in both the soleus and tibialis anterior muscles, and significant decreases in subcutaneous fat. Increases in TA and SOL IMCL correlated with oleic and palmitic acid FFA concentrations respectively. The compositional change of IMCL during the fast related inversely to the baseline composition, suggesting a selective efflux of unsaturated shorter chain IMCLs for preferential oxidation, which is in agreement with rat biopsy data, and supportive of the idea of IMCL as a flexible lipid store.

3439

Identification and in vivo quantification of fatty acid metabolism in liver of a lipogenic methionine-choline-deficient diet-fed animal model by using magnetic resonance spectroscopy at 9.4 T

Kyu-Ho Song¹, Song-I Lim¹, Min Young Lee¹, Chi-Hyeon Yoo¹, and Bo-Young Choe¹

¹Department of Biomedical Engineering, and Research Institute of Biomedical Engineering, The Catholic University of Korea College of Medicine, Seoul, Korea, Republic of

Non-alcoholic steatohepatitis (NASH) is associated with metabolic syndrome as a result of insulin resistance and the accumulation of lipid droplets within hepatocytes. There is a need to diagnose and to accurately assess the progressive severity of hepatic steatosis with non-invasive biomarkers that are distinguishable from those in non-alcoholic fatty liver disease (NAFLD). Our findings demonstrate that fatty acid metabolism (saturated- and unsaturated-fatty acids) of hepatic steatosis induced by a methionine-choline diet can be distinguished from progressive NAFLD by using high-resolution magnetic resonance spectroscopy (MRS).

Metabolic Imaging of Brown Adipose Tissue Activation by Exercise in Control and High Fat Diet Fed Rats

Venkatesh Gopalan¹, Jagdeoud Yaligar¹, Sanjay Kumar Verma¹, Suresh Anand Sadananthan², Anna Ulyanova¹, Navin Michael², Anantharaj Rengaraj¹, Tian Xianfeng¹, and S. Sendhil Velan^{1,2}

¹Laboratory of Molecular Imaging, Singapore Biomedicine Consortium, Singapore, Singapore, ²Singapore Institute for Clinical Sciences, Singapore, Singapore

Exercise is an important intervention for correction of irregular fat-partitioning and treatment of metabolic dysfunction. There is a large interest in development of non-invasive methods for activation of brown adipose tissue (BAT) due to its potential to combat obesity. In this study we have investigated exercise induced BAT activation and IMCL from skeletal muscle of rodents fed with control and high fat diet. Our results show that exercise modulates the brown fat with reduction in fat fraction, increased UCP1 expression and reduction in "white" like adipocytes in control and high fat diet fed rats.

3441

Computer 111 Metabolic Imaging of Aging Adipose Tissues

Venkatesh Gopalan¹, Sanjay Kumar Verma¹, Jadegoud Yaligar¹, Anantharaj Rengaraj¹, Tian Xianfeng¹, Bhanu Prakash K N¹, Suresh Anand Sadananthan², Navin Michael², and S. Sendhil Velan^{1,2}

¹Laboratory of Molecular Imaging, Singapore Bioimaging Consortium, Singapore, Singapore, ²Singapore Institute for Clinical Sciences, Singapore, Singapore

There is a global interest in healthy aging and also to avoid metabolic dysfunction. BAT and WAT play an important role in modulating the energy expenditure. In this study we have investigated the interscapular BAT and abdominal adipose tissues in young and old rats. During aging the iBAT activity is reduced due to the increase in "white" like adipocytes. The abdominal adipose tissues including VAT and SAT show increase in adipocyte size resulting in hypertrophy. Modulating these fat depots with nutritional interventions is of significant clinical interest.

3442

Computer 112 Automated MRI fat quantification in obese patients – impact of reader experience and degree of obesity on time exposure

The last decades have seen an increasing socioeconomic impact of obesity and obesity-related diseases. Noninvasive measures like subcutaneous and visceral adipose tissue (SAT, VAT) amounts and are also increasingly correlated with other, often clinical or metabolic findings as well as independent patient characteristics, even interventional complication rates. MRI fat quantification is common but manual processing is often laborious and time consuming while fully automatic segmentation is prone to errors. This work takes a custom-made semiautomatic MRI tool and prospectively analyzes the processing and interaction times for readers with different experience as well as patients from different BMI groups.

3443

Computer 113 Preliminary study for the quantification of fatty composition and relation to metabolic syndrome using modified Dixon method.

We successfully quantified fatty acid composition in the liver, subcutaneous, and visceral fat tissue using modified Dixon technique with flexible six echo times and seven-peak spectral model with lipid components. Our results suggested that fatty acid composition of depot fat was varied among the patients with different metabolic status. We also demonstrated the possible relationship of unsaturated fatty acid in depot fat to cholesterol level and insulin tolerance.

Computer 114 Liver and muscle energy metabolism in patients with organic acidemias using 31P and 1H MR spectroscopy

Alessandra Bierwagen^{1,2}, Daria Caspari³, Maik Rothe^{1,2}, Klaus Straßburger^{2,4}, Jong-Hee Hwang^{1,2}, Michael Roden^{1,2,5}, and Regina Ensenauer³

¹Institute for Clinical Diabetology, German Diabetes Center, Leibniz Institute for Diabetes Research, Heinrich Heine University, Duesseldorf, Germany, ²German Center for Diabetes Research (DZD e.V.), Partner Düsseldorf, Duesseldorf, Germany, ³Experimental Pediatrics and Metabolism, University Children's Hospital, Heinrich Heine University, Duesseldorf, Germany, ⁴Institute for Biometrics and Epidemiology, German Diabetes Center, Leibniz Institute for Diabetes Research, Heinrich Heine University, Duesseldorf, Germany, ⁵Department of Endocrinology and Diabetology, Medical Faculty, Heinrich Heine University, Duesseldorf, Germany

This study assessed energy and fat metabolism in a well phenotyped cohort of patients with organic acidemias using non-invasive MR spectroscopy. ³¹P and ¹H spectra of the liver as well as ¹H spectra of the muscle were acquired in 27 patients and 30 healthy controls (age-, sex-, BMI-matched). We found higher liver fat content in patients with propionic acidemia. The level of creatine in the soleus muscle was higher in patients with methylmalonic acidemia and propionic acidemia. In conclusion, the results provide evidence for previously unknown abnormalities of liver fat and muscle energy metabolism in patients with organic acidemias.

Computer 115 Validity of estimating subcutaneous and visceral fat volume from single MRI slice in older adults with sarcopenia and sarcopenic obesity

Yu Xin Yang¹, Wee Shiong Lim^{1,2}, Mei Sian Chong¹, Laura Tay^{1,2}, Suzanne Yew¹, Audrey Yeo¹, and Cher Heng Tan³

¹Institute of Geriatrics and Active Ageing, Tan Tock Seng Hospital, Singapore, Singapore, ²Geriatric Medicine, Tan Tock Seng Hospital, Singapore, Singapore, ³Diagnostic Radiology, Tan Tock Seng Hospital, Singapore, Singapore

The demand for measurements of fat quantities is driven by the rising prevalence of sarcopenia and sarcopenic obesity (SO). In order to reduce the time and the cost of image processing, several studies have estimated the subcutaneous fat (SF) and visceral fat (VF) volume from a single slice. However, the population of studies may not have necessarily included patients with either sarcopenia or SO. This study aims to determine the correlation between the cross-sectional areas in a single slice at different vertebra levels and the volumes of SF and VF in the abdomen for sarcopenic and SO populations using MRI.

Computer 116 Water-fat MRI demonstrates seasonal proliferation of brown adipose tissue near the eyes of juvenile hibernators: An additive effect of cold exposure

Amanda DV MacCannell¹, Kevin Sinclair², Lannete Friesen-Waldner², Charles A McKenzie², and James Staples¹

¹Biology, University of Western Ontario, London, ON, Canada, ²Medical Biophysics, University of Western Ontario, London, ON, Canada

Hibernating mammals use brown adipose tissue (BAT) as a primary source of heat production. Volumes of both white adipose tissue (WAT) and BAT increase in the autumn even when temperatures are warm. Between Aug 19th and Oct 13th we used water-fat MRI to measure the dynamics of BAT and white adipose tissue as ground squirrels prepared for hibernation under either cold or thermoneutral temperatures. We found that the volume of a tissue that resembles BAT around the eye, increased significantly in cold exposed animals to warm exposed in October, as the animals are preparing for winter.

This work monitored longitudinal changes in visceral (VAT) and subcutaneous (SCAT) adipose tissue in response to weight loss. Twenty-one patients undergoing clinical weight loss surgery (WLS) were recruited for 5 MRI studies: 2-3 weeks prior, 1 day prior to WLS and 1, 3, and 6 months post-WLS. Single breath-hold, chemical shift encoded acquisitions were analyzed using an Osirix semi-automated segmentation software to monitor changes in VAT and SCAT volumes. Continual reductions in VAT and SCAT were measured over the five visits. At every visit, each patient's relative body fat distribution remained relatively constant despite overall reductions in both VAT and SCAT.

- 3451 **Computer 1** [Quantitation of DTI changes associated with muscle injury using a 3D printed phantom](#)

 David B Berry¹, Shangting You², John Warner², Lawrence Frank³, Shaochen Chen², and Samuel R Ward^{1,3,4}
¹Bioengineering, University of California, San Diego, San Diego, CA, United States, ²Nanoengineering, University of California, San Diego, San Diego, CA, United States, ³Radiology, University of California, San Diego, San Diego, CA, United States, ⁴Orthopaedic Surgery, University of California, San Diego, San Diego, CA, United States
- Diffusion tensor imaging has been proposed as a tool to non-invasively assess skeletal muscle microstructure, which would be of significant clinical value. However, its application to the assessment of changes in muscle microstructure associated with injury, pathology, or age remain poorly defined because it is difficult to precisely control muscle microstructural features in vivo. Recent advances in bottom up fabrication technologies allow precision-engineered diffusion phantoms with histology informed skeletal muscle geometry to be manufactured. Therefore, the goal of this study was to develop skeletal muscle phantoms at relevant size scales in order to relate microstructural features to MRI-based diffusion measurements.

¹Radiology and Nuclear Medicine, Erasmus Medical Center, Rotterdam, Netherlands, ²Medical Informatics and Radiology, Erasmus Medical Center, Rotterdam, Netherlands, ³Imaging Science and Technology, Delft University of Technology, Delft, Netherlands
- Diffusion weighted STEAM with UTE readout is a promising acquisition method to measure diffusion in tissues with short T2 and T2*, such as tendons, ligaments and menisci. However, the accuracy of the ADC obtained with this method has not been studied before. Using experiments and Bloch simulations we show that the ADC can be biased, especially when a short TR is used, and that this bias depends on T1 and T2. Randomization of the diffusion gradient direction reduces the bias, providing clear suggestions to improve acquisition and/or post processing that reduces the ADC bias.

- This work investigates the stability of a water-based biomimetic tumour tissue phantom, and evaluates its potential as a tool for validating diffusion-weighted (DW) MRI measurements. As with biological tissue, and unlike most previous phantoms for tumour DW-MRI, the phantom's apparent diffusion coefficient depends on diffusion time, with values stable over six months. DW-MRI-based estimates of microstructural parameters exhibited bias, possibly indicating limitations in the analysis model or acquisition scheme. It is envisaged that such phantoms will aid investigation of DW-MRI tumour microstructural models, and more generally will act as realistic test objects for comparing DW-MRI-derived biomarkers obtained from different scanners/sites.

¹Radiology, University of Pittsburgh, Pittsburgh, PA, United States, ²Radiology, Children's Hospital of Pittsburgh UPMC, Pittsburgh, PA, United States, ³Radiology, University of Michigan, Ann Arbor, MI, United States, ⁴Radiology, Boston Children's Hospital, Boston, MA, United States, ⁵Radiology and Imaging Sciences, Emory University School of Medicine, Atlanta, GA, United States, ⁶Radiology, Medical College of Wisconsin, Milwaukee, WI, United States, ⁷Radiology, Children's Hospital of Philadelphia, Philadelphia, PA, United States, ⁸Psychology, Carnegie Mellon University, Pittsburgh, PA, United States, ⁹Neurological Surgery, University of Pittsburgh, Pittsburgh, PA, United States

In this study we explore whether scanner-related-variabilities contribute to an individual's distinct fingerprint – and whether the fingerprint specificity would be robust as a biomarker by scanning the same subject across multiple vendors and multiple scanner in four institutions. Both Diffusion Tensor Imaging and Multi-shell Multi-band diffusion imaging (MSMBDI) was tested, and differences within acquisition type (using fractional anisotropy and normalized quantitative anisotropy) and between acquisition types comparisons (using q-space diffeomorphic reconstruction) analysis were examined. We found that scanner may contribute partly to the fingerprint pattern, but the fingerprint was robust at maintaining pattern, especially in MSMBDI to warrant further studies.

Quantitative evaluation of PROPELLER DWI using QIBA diffusion phantom

Joshua Yung¹, Hua Ai¹, Ho-Ling Liu¹, and R Jason Stafford¹

¹Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston, TX, United States

The purpose of this study was to characterize ADC values when varying imaging parameters in a diffusion-weighted (DW) FSE sequence with Periodically Rotated Overlapping Parallel Lines with Enhanced Reconstruction (PROPELLER) k-space trajectory. The QIBA diffusion phantom was used to quantitatively evaluate the different pulse sequences. The DW PROPELLER sequence showed good agreement with the QIBA SE EPI sequence with the ETL=20 and b-value of 0 and 2000 s/mm² sequence having with a r²=0.9034. The DW PROPELLER sequence is promising for quantitative evaluation of ADC values and this study may help improve clinical protocols using diffusion weighted imaging.

Computer 8

Quantitative evaluation of apparent diffusion coefficient in a large multi-unit institution using QIBA diffusion phantom

Joshua Yung¹, Yao Ding¹, Ken-Pin Hwang¹, Carlos E Cardenas^{2,3}, Hua Ai¹, Michael A Boss⁴, Thomas L Chenevert⁵, Clifton Fuller⁶, and R Jason Stafford¹

¹Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston, TX, United States, ²Radiation Physics, The University of Texas MD Anderson Cancer Center, Houston, TX, United States, ³The University of Texas Graduate School of Biomedical Sciences, Houston, TX, United States, ⁴Physical Measurement Laboratory, National Institute of Standards and Technology, Boulder, CO, United States, ⁵Radiology, University of Michigan, Ann Arbor, MI, United States, ⁶Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX, United States

The purpose of this study was to determine the quantitative variability of apparent diffusion coefficient values across a large fleet of MR systems. Using a NIST traceable magnetic resonance imaging diffusion phantom, imaging was reproducible and the measurements were quantitatively compared to known values. Significant differences in identical phantoms were not observed, but uncertainty in the measurements was seen at low apparent diffusion coefficient values. The same trend was observed when the diffusion phantoms were imaged in 20 different MR systems. The characterization of ADC variability for these systems provides an improved quality control for quantitative diffusion weighted imaging.

Computer 10

A Novel Yeast Cells- and Microcapillaries-Based Phantom for Validation of Diffusion MRI Models

Shir Levy¹, Darya Morozov¹, Inbar Seroussi², Leah Bar², Nir Sochen², and Yoram Cohen^{1,3}

¹School of Chemistry, The Raymond and Beverly Sackler Faculty of Exact Science, Tel Aviv University, Tel Aviv, Israel, ²School of Mathematical Sciences, The Raymond and Beverly Sackler Faculty of Exact Science, Tel Aviv University, Tel Aviv, Israel, ³Sagol School of Neuroscience, Tel Aviv University, Tel Aviv, Israel

Numerous different models provide detailed microstructure information from diffusion MRI data. In order to challenge them, there is a need for complex phantoms with known structural characteristics. For this purpose, we present a novel phantom, consists of spherical fixed yeast cells and cylindrical microcapillaries. Despite of its complexity, arising from the different size, geometry and size distribution of the restricted compartments, there is a good correlation between the known ground truth and the features that were extracted from fitting single diffusion encoding (SDE) MRI experimental data, assuming continued or discrete weight of size distribution.

Computer 11

The use of novel validation methods to investigate optimal ROI location and probabilistic thresholds in tractography for presurgical planning in brain tumour patients.

Gideon Ayokunmi Oluniran^{1,2}, Marcelo Lemos¹, Jeorg Ederle³, Jozef Jarosz⁴, Gareth John Barker¹, and Jonathan Ashmore⁴

¹Neuroimaging, King's College London, London, United Kingdom, ²Physics, Federal University, Ndufu-Alike, Ikwo, Abakaliki, Ebonyi State, Nigeria, ³Neuroradiology, King's College Hospital, London, United Kingdom, ⁴Neuroradiology, King's College Hospital, London, United Kingdom

Although advanced tractography techniques exist and are well documented, many validation methods are not applicable to brain tumour cases and do not examine the possibility of proposing standard probabilistic thresholds. Using a novel approach, we investigate certain thresholds ('safe' thresholds) which can be applied to probabilistic tractography to reduce false representation of tracts, aid maximal tumour resection, and limit neurofunctional deficit from surgical treatments. We also examine optimal region of interest (ROI) location. 'Safe' thresholds can be determined, and with a wider confidence when tractography is defined with inclusion regions.

Theory, validation and application of blind source separation to diffusion MRI for tissue characterisation and partial volume correction
Miguel Molina-Romero^{1,2}, Pedro A Gómez^{1,2}, Jonathan I Sperl², Andrew J Stewart³, Derek K Jones⁴, Marion I Menzel², and Bjoern H Menze¹

¹Technische Universität München, Munich, Germany, ²GE Global Research Europe, Garching, Germany, ³EMRIC, Cardiff University, Cardiff, United Kingdom, ⁴CUBRIC, Cardiff University, Cardiff, United Kingdom

Here we present blind source separation (BSS) as a new tool to analyse multi-echo diffusion data. This technique is designed to separate mixed signals and is widely used in audio and image processing. Interestingly, when it is applied to diffusion MRI, we obtain the diffusion signal from each water compartment, what makes BSS optimal for partial volume effects correction. Besides, tissue characteristic parameters are also estimated. Here, we first state the theoretical framework; second, we optimise the acquisition protocol; third, we validate the method with a two compartments phantom; and finally, show an in-vivo application of partial volume correction.

3463

Computer 13

Histological validation of microstructural measures derived from the PICASO model

Lipeng Ning¹, Tanguy Duval², Julien Cohen-Adad², and Yogesh Rathi¹

¹Harvard Medical School, Boston, MA, United States, ²Polytechnique Montréal

We propose to validate the PICASO (Precise Inference and Characterization of Structural Organization)¹ biophysical model of tissue microstructure using a full-slice histology of cat spinal cord. The PICASO model was fit to high resolution diffusion MRI (dMRI) of a cat spinal cord to estimate microstructural measures of diffusion disturbance, which is directly related to axonal packing and density. We found that the structural disturbance coefficient (SDC) in the direction orthogonal to the fiber orientation from the PICASO model was strongly correlated with the axonal density obtained from histology² with a correlation coefficient of $r=0.67$. Thus, the SDC could provide very precise information about the microscopic arrangement of axons or cells in biological tissue.

¹Radiology, Juntendo University School of Medicine, Tokyo, Japan, ²Research Institute for Diseases of Old Age, Juntendo University Graduate School of Medicine, Tokyo, Japan, ³Research & Development Group, Hitachi Ltd., Tokyo, Japan, ⁴Neuropathology, Tokyo Medical and Dental University, Tokyo, Japan, ⁵Radiological Sciences, Tokyo Metropolitan University Graduate School of Human Health Sciences, Tokyo, Japan, ⁶Psychology, Chukyo University, Nagoya, Japan, ⁷Araya Brain Imaging, Tokyo, Japan

Diffusional kurtosis imaging (DKI) is a sensitive technique to analyze brain microstructure but that has little histological foundation. In this study, we evaluated a relationship between DKI parameters with neurite density measured by a confocal microscopy of the cleared mouse brain. There was a strongly positive correlation between neurite density and DKI parameters in the caudate nucleus and putamen, whereas the correlation between neurite density and fractional anisotropy was moderate. DKI reflect neurite density in an area with crossing fibers, so that can evaluate more complex microstructures than diffusion tensor imaging.

3465

Computer 15

An affordable phantom for ADC/FA; a device for multi-site studies

Koji Sakai¹, Toshiaki Nakagawa², Ryusuke Nakai^{3,4}, Hiroyasu Ikeno², Seiji Yamaguchi³, Hiroaki Takadama³, and Kei Yamada¹

¹Kyoto Prefectural University of Medicine, Kyoto, Japan, ²Kyoto Prefectural University of Medicine Hospital, ³Chubu University, ⁴Kyoto University

Multi-site study gives large statistical power for the results. Some intrinsic differences among scanners are recognizing as an inevitable property. Isotropic diffusion has already been discussing. In contrast, anisotropic diffusion has been evading the endeavor because of the absence of an easily available anisotropic diffusion phantom. We compared DTI measures among five different MR scanners at three different sites using commercially and easily available astriction cotton. The averaged coefficient of variation for longitudinal repeated acquisitions of DTI on five different MR scanners were stable. The scan-rescan properties of five different MR scanners can be comparable by anisotropic diffusion phantom.

3466

Computer 16

Reduction of susceptibility-induced field gradients in multi-fibre diffusion phantoms via susceptibility matching

Ezequiel Farrher¹, Johannes Lindemeyer¹, Farida Grinberg^{1,2}, Ana-Maria Oros-Peusquens¹, and N. Jon Shah^{1,2,3}

¹Institute of Neuroscience and Medicine 4, Forschungszentrum Jülich, Jülich, Germany, ²Department of Neurology, Faculty of Medicine, RWTH Aachen University, Aachen, Germany, ³JARA – BRAIN – Translational Medicine, RWTH Aachen University, Aachen, Germany

Studies performing diffusion-weighted MRI on anisotropic fibre phantoms suffer from microscopic background field gradients induced by differences in the magnetic susceptibility of the employed materials. We present a particularly promising approach that makes use of a matched magnesium chloride solution to eliminate these effects. The method is thoroughly studied and successfully validated on a crossing-fibre phantom containing two perpendicularly crossing fibre populations. The obtained results are no longer subject to any orientation-dependence with respect to B_0 .

¹Applied MRI Research, Molecular Imaging and Theranostics, National Institute of Radiological Sciences, National Institutes for Quantum and Radiological Science and Technology, Chiba, Japan, ²Department of Oral and Maxillofacial Radiology, Tokyo Dental College, Tokyo, Japan, ³Department of Nuclear Medicine, Kawasaki Medical School, ⁴Department of Nuclear Medicine, Cancer Institute Hospital, Japanese Foundation for Cancer Research, ⁵Molecular Imaging and Theranostics, National Institute of Radiological Sciences, ⁶Department of Radiopharmaceuticals Development, National Institute of Radiological Sciences, ⁷National Institute of Radiological Sciences Hospital, ⁸Diagnostic Radiology and Radiation Oncology, Graduate School of Medicine, Chiba University, ⁹Department of Diagnostic Imaging and Nuclear Medicine, Kyoto University

To investigate the usefulness of diffusion-weighted imaging (DWI) for visualizing hypoxia of head and neck carcinoma, the correlation between DWI parameter estimates and ¹⁸F-fluorazomycin arabinoside (FAZA) positron emission tomography (PET) activity was evaluated. The diffusion coefficients and fractions of the fast and slow compartments according to the 2-compartment model (D_{fast} , D_{slow} and F_{fast} , F_{slow}) were estimated. The diffusional kurtosis (K) and the corrected diffusion coefficient (D) were also obtained according to the diffusional kurtosis imaging (DKI) method. Amongst the DWI estimates, D_{slow} and K were significantly correlated with FAZA-PET activity, which suggests they might be useful as indicators of hypoxia.

7.0 T Diffusion Tensor Imaging Evaluation of Rabbit Sciatic Nerve Microstructure with Histologic Correlation

Tina Jeon¹, Emil Stefan Vutescu², Eric Aronowitz³, Henning U Voss³, Jonathan P Dyke³, and Darryl B Sneag¹

¹Radiology and Imaging, Hospital for Special Surgery, New York, NY, United States, ²3Department of Hand and Upper Extremity Service, Hospital for Special Surgery, New York, NY, United States, ³Citigroup Biomedical Imaging Center, Weill Cornell Medical College, New York, NY

High-resolution DTI is a promising tool to evaluate peripheral nerve regeneration following surgical repair of nerve injury. The spatial resolution achieved with 7.0 T allowed us to more confidently interrogate the nerve for measuring fractional anisotropy (FA) and diffusivity and to perform fiber tracking as compared to 3.0 T. Among DTI metrics, FA correlated the greatest with axonal density and diameter. These findings support that DTI has the potential to measure axonal regeneration in the peripheral nerves at preclinical and clinical field strengths.

Diffusion-weighted MRI of node tissue: correlation of mean diffusivities and cellularity.

Mariaulpa Sahalan¹, Aritrick Chatterjee¹, Nyoman Kurniawan², Gary Cowin², Laurence Gluch³, Carl Power⁴, Geoffrey Watson⁵, Kevin Tay⁶, Julie Fletcher⁷, David Taylor⁸, and Roger Bourne¹

¹Faculty of Health Sciences, The University of Sydney, NSW, Australia, ²Centre for Advanced Imaging, University of Queensland, Brisbane, Australia, ³The Strathfield Breast Centre, NSW, Australia, ⁴Biological Resources Imaging Laboratory, University of New South Wales, NSW, Australia, ⁵Tissue Pathology and Diagnostic Oncology, Royal Prince Alfred Hospital, NSW, Australia, ⁶Westmead Breast Cancer Institute, NSW, Australia, ⁷Concord Repatriation General Hospital, NSW, Australia, ⁸Vetnostics, NSW, Australia

Improvement of sensitivity and specificity in DWI-based assessment of nodal diseases is dependent on a better understanding of how nodal microstructures affect the water diffusivity in tissue. In this abstract we report the first diffusion microimaging investigation of formalin fixed node tissue with the aim of assessing any correlation between mean diffusivity and cellularity. Mean diffusivity was calculated in ROI corresponding to distinct node sub-structures. Nuclei were segmented semi-automatically to measure the cellularity metrics: nuclear count and nuclear area. The results showed there is no significant correlation between mean diffusivity with cellularity metrics in the nodal tissues.

3471

Computer 21

Reproducibility of SMT-Based Microscopic Diffusion Anisotropy Imaging on a Clinical MRI System

Cara Louise Foley¹, Enrico Kaden², Kiran Seunarine¹, Matt Hall¹, David Carmichael¹, Jonathan Clayden¹, and Chris Clark¹

¹Developmental Imaging & Biophysics, University College London, London, United Kingdom, ²Centre of Medical Image Computing, University College London, London, United Kingdom

Diffusion Tensor Imaging (DTI) is a widely used neuroimaging technique, but it lacks specificity. Advanced diffusion models aim to yield greater biophysical information than DTI. This information is redundant if the parameters cannot be accurately reproduced across time-points. Multi-shell diffusion images were acquired on a single 3T scanner at two time-points for ten healthy adults. Mean parameter values from SMT-based microscopic diffusion anisotropy imaging and DTI were obtained in white matter, cortex and thalami. The advanced model performed similarly well to DTI in white matter, but was less consistent in the cortex and thalami, potentially due to its increased complexity.

3472

Computer 22

Scan-rescan of AxCaliber, macromolecular tissue volume and g-ratio in the spinal cord
Tanguy Duval¹, Victoria Smith², Eric Klawiter², Nikola Stikov^{1,3}, and Julien Cohen-Adad^{1,4}

¹NeuroPoly Lab, Institute of Biomedical Engineering, Polytechnique Montreal, Montreal, QC, Canada, ²A.A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, ³Montreal Heart Institute, Montreal, QC, Canada, ⁴Functional Neuroimaging Unit, CRIUGM, Montreal, QC, Canada

Translating quantitative MRI to clinical research raises many challenges in term of acquisition strategy, modeling of the MRI signal, artifact corrections (sensitivity to motion and distortion) and metric extraction (template registration and partial volume effects). In this work, we wanted to validate the repeatability of this entire framework, from the acquisition to the extraction of the metrics using a template-based approach. We took advantage of the 300 mT/m gradients from the connectome scanner for estimating robustly AxCaliber metrics, MTV, and g-ratio in the spinal cord of eight healthy subjects, scanned and rescanned in two different sessions. Our results show good scan-rescan repeatability ($r > 0.7$, small deviations $< 5\%$), and demonstrate the capability of these metrics to detect inter-subjects (through ICC) and inter-fiber-pathways differences (through ANOVA analysis).

Reducing complexity of functional imaging: free-breathing imaging based ADC and IVIM measurements are as accurate as breath-hold measurements in renal cell carcinoma

Neil P Jerome^{1,2}, Matthew R Orton², James A d'Arcy², David J Collins², Martin O Leach², and Dow-Mu Koh³

¹Department of Circulation and Medical Imaging, NTNU - Norwegian University of Science and Technology, Trondheim, Norway, ²Radiotherapy & Imaging, The Institute of Cancer Research, London, United Kingdom, ³Department of Radiology, The Royal Marsden Hospital, London, United Kingdom

Respiratory motion represents a serious confounding factor for abdominal imaging; for more complex diffusion models such as IVIM, acquisition of diffusion-weighted images in successive breath-holds offers control of motion for sharper images. In this patient study, DWI was performed in free-breathing and consecutive breath-holds, without registration, on successive days without intervention to determine repeatability. Derived tumour ROI parameters from ADC and IVIM models were not significantly affected between breathing regimes, but observed coefficients of variation for free-breathing were smaller for all pseudo-diffusion related parameters. Breath-holding is time inefficient, and free-breathing allows more data collection for development of robust DWI markers.

When does a volume of a bundle achieve saturation? A microstructure informed tractography study

Muhamed Barakovic¹, David Romascano¹, Gabriel Girard¹, Maxime Descoteaux^{1,2}, Jean-Philippe Thiran^{1,3}, and Alessandro Daducci^{1,3,4}

¹Signal Processing Lab (LTS5), École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ²Sheerbrooke Connectivity Imaging Laboratory (SCIL), University of Sheerbrooke, Canada, ³University Hospital Center (CHUV) and University of Lausanne (UNIL), Switzerland, ⁴Department of Computer Science, University of Verona, Italy

Volumetric analysis of bundles derived from tractography is a popular statistical measure used in neurological disorder studies. Recent research performed by Gauvin shows that different bundles saturate with different tractography parameters, however, to achieve that saturation millions of streamlines need to be computed. In this investigation, the aim was to use microstructure informed tractography, a novel technique that combine tractography and microstructure models, to study the saturation of the bundles. This study has found that generally microstructure informed tractography makes the volume estimation less sensitive to tracking parameters. The findings may have profound implications in volumetric analysis in group studies.

Structure tensor informed fibre tractography at 3T

Kwok-shing Chan¹, David G. Norris¹, and José P. Marques¹

¹Donders Centre for Cognitive Neuroimaging, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands

Structure tensor informed fibre tractography (STIFT) based on diffusion images at 3T and gradient-echo images at 7T has shown improvement in the accuracy of white matter bundles tracking in the presence of kissing and crossing fibres. In this study, we implemented STIFT using both DWI and GRE images at 3T. We further demonstrated white matter contrast presence in T_2^* mapping and quantitative susceptibility mapping derived from GRE data can be used to compute structure tensor. The benefits of STIFT are shown in two tractography applications.

Stability metrics for optic radiation tractography: towards damage prediction after resective surgery

Stephan Meesters^{1,2}, Pauly Ossenblok^{2,3}, Louis Wagner², Olaf Schijns^{2,4}, Paul Boon², Luc Florack¹, Anna Vilanova^{3,5}, and Remco Duits¹

¹Mathematics and Computer Science, Eindhoven University of Technology, Eindhoven, Netherlands, ²Academic Center for Epileptology Kempenhaeghe & Maastricht UMC+, Heeze, Netherlands, ³Biomedical Engineering, Eindhoven University of Technology, Eindhoven, Netherlands, ⁴Neurosurgery, Maastricht UMC+, Maastricht, Netherlands, ⁵Mathematics and Computer Science, Delft University of Technology, Delft, Netherlands

An accurate delineation of the optic radiation (OR) is useful in reducing the risk of a visual field deficit after temporal lobe resective surgery. However, tractography, especially of the probabilistic kind, is prone to generate spurious (false-positive) streamlines that are poorly aligned with the surrounding bundle. Fiber-to-bundle coherence measures are applied to identify and remove spurious fibers, which together with test-retest parameter estimation can provide a reconstruction of the OR that is robust to the stochastic realization of probabilistic tractography. Pre- and post-operative comparison of the OR is performed for epilepsy patients to quantify the accuracy of damage prediction.

Structural Connectivity Within Neural Ganglia: A Default Small-World Network

Abdol Aziz O. Ould Ismail^{1,2}, Ghoncheh Amouzandeh^{1,3}, and Samuel Colles Grant^{1,2}

¹Center for Interdisciplinary Magnetic Resonance, Florida State University, Tallahassee, FL, United States, ²Chemical & Biomedical Engineering, Florida State University, Tallahassee, FL, United States, ³Physics, Florida State University, Tallahassee, FL, United States

Diffusion tensor imaging (DTI) provides a unique contrast based on the restricted directionality of water movement in an anisotropic environment. As such, DTI-based tractography can be used to characterize and quantify the structural connectivity within neural tissue. Here, structural connectivity within isolated abdominal neural ganglia of *Aplysia californica* (ABG) is assessed by integrating DTI and network theoretical analysis. For ABG, findings demonstrate a default structural network with preferential specific small-world properties when compared to simulated lattice and random networks that are equivalent in order and degree.

Atlas Construction in Diffusion MRI via Angular Patch Matching

Zhanlong Yang^{1,2}, Geng Chen², Dinggang Shen², and Pew-Thian Yap²

¹College of Marine, Northwestern Polytechnical University, Xi'an, People's Republic of China, ²Department of Radiology and BRIC, UNC Chapel Hill, Chapel Hill, NC, United States

Construction of brain atlases is generally carried out using a two-step procedure involving registering a population of images to a common space and then fusing the aligned images to form an atlas. In practice, image registration is not perfect and simple averaging of the images will blur structures and cause artifacts. In diffusion MRI, the problem is even more challenging, since the alignment of gross anatomical structures does not necessarily guarantee the alignment of the microstructural information captured in each voxel. In this situation, it is unclear for example how signals characterizing fiber bundles of varying orientations, which can occur naturally across subjects, should be fused to form the atlas. Moreover, the commonly used simple averaging method is sensitive to outliers.

The impact of High-Q and High-K on complex fiber structures in the human brain

Iain Bruce¹, Christopher Petty¹, Hing-Chiu Chang², Nan-Kuei Chen^{1,3}, and Allen W Song¹

¹Brain Imaging and Analysis Center, Duke University Medical Center, Durham, NC, United States, ²Department of Diagnostic Radiology, University of Hong Kong, ³Biomedical Engineering, University of Arizona, Tuscan, AZ, United States

In this diffusion MRI study, we investigated the impact of high angular resolution (high-Q) and high spatial resolution (high-K) on complex fiber structures. It was found that while high-Q was able to resolve crossing fibers within a given region, high-K provided additional spatial details of these crossing fibers in the same location. In addition, diffusion data from high-K improved characterization of high-curvature fibers, which cannot be adequately resolved with high-Q. It is thus concluded that high-K is preferred when both crossing and high-curvature fibers need to be resolved, as in human connectome analysis.

REPRODUCIBILITY OF GRAPH METRICS ESTIMATED FROM ALTERNATIVE STRATEGIES OF NETWORK WEIGHTING:EVIDENCES FROM REPEAT MRI SCANS

STAVROS I DIMITRIADIS^{1,2}, MARK DRAKESMITH², SONYA BELLS³, GREG PARKER³, DAVID LINDEN³, and DEREK K JONES⁴

¹SCHOOL OF MEDICINE, Institute of Psychological Medicine and Clinical Neurosciences, Cardiff University School of Medicine, CARDIFF, United Kingdom, ²SCHOOL OF MEDICINE, Cardiff University Brain Research Imaging Center (CUBRIC), School of Psychology, Cardiff University, Cardiff, United Kingdom, CARDIFF, United Kingdom, ³SCHOOL OF PSYCHOLOGY, Cardiff University Brain Research Imaging Center (CUBRIC), School of Psychology, Cardiff University, Cardiff, United Kingdom, CARDIFF, United Kingdom, ⁴SCHOOL OF PSYCHOLOGY, CARDIFF, United Kingdom

Sinopsis: To evaluate the reliability of well-known network metrics over alternative weighting strategies using diffusion MRI. Methods: Using ten different network weighting strategies to construct structural networks from repeat dMRI scans, we estimated the reliability of network metrics estimated over the networks. Additionally, the recognition accuracy was estimated for each of the ten strategies. Results: We demonstrated excellent ICC for six network metrics for the seven out of network weighting strategies. Recognition accuracy was 100% accurate for the number and percentage of streamlines and tract volume. Conclusions: Our results highlight the importance of reliable network metrics from structural brain networks.

Hemispheric asymmetries and grey matter projections of the arcuate fasciculus: an along-tract study of diffusion and localization properties with deterministic and probabilistic tractography

Lia Talozzi¹, Claudia Testa¹, Stefano Zanigni¹, Stefania Evangelisti¹, Laura Ludovica Gramegna¹, Claudio Bianchini¹, Paola Fantazzini^{2,3}, Caterina Tonon¹, David Neil Manners¹, and Raffaele Lodi¹

¹Department of Biomedical and NeuroMotor Sciences, University of Bologna and Functional MR Unit, Policlinico S. Orsola - Malpighi, Bologna, Italy, ²Department of Physics and Astronomy, University of Bologna, Italy, ³Centro Enrico Fermi, Roma, Italy

We studied the arcuate fasciculus in both cerebral hemispheres in 29 healthy subjects, by evaluating GM projections and along-tract diffusion properties and tract curvature, obtained with three tractography methods: probabilistic ball-and-sticks model, deterministic and probabilistic spherical deconvolution. In all subjects we detected the arcuate in both hemispheres. For all the tractography methods we measured a bigger tract volume on the left, but detected more tracts branching towards GM terminations on the left only with the probabilistic methods, that influenced both the tract curvature and its diffusion parameters. The probabilistic tractography methods better described arcuate connectivity, which is more complex in the left hemisphere.

¹College of Computer Science and Technology, Harbin Engineering University, Harbin, People's Republic of China, ²Psychiatry Neuroimaging Laboratory, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ³Department of Radiology, Children's Hospital of Boston, Boston, MA, United States, ⁴Department of Psychiatry, Children's Hospital of Boston, Boston, MA, United States, ⁵Fetal-Neonatal Neuroimaging and Developmental Science Center, Children's Hospital of Boston, Boston, MA, United States, ⁶Scientific Review and Behavioral Science Core, Children's Hospital of Boston, Boston, MA, United States

Structural abnormalities in frontal lobe connections have been observed in adults/children with ADHD in earlier studies using diffusion tensor imaging (DTI)³. This abstract investigates microstructural differences in frontal-lobe white matter connectivity using advanced diffusion imaging methods. 47 white matter fiber bundles connecting frontal areas as parcellated by Freesurfer were extracted using a novel whole-brain tractography algorithm^{4,1}, which allowed estimation of specific diffusion properties such as cellular volume and cellular density from advanced diffusion MRI (dMRI) data. After correcting for multiple comparisons, 6 significant white matter pathways were found to have lower cellular volume and density in ADHD compared to controls.

Hyper-connectivity of the Seizure Onset Zone: A Potential Epilepsy Biomarker at 7T

Jack Rutland^{1,2}, Rebecca Feldman¹, Lara Marcuse³, Madeline Fields³, Bradley Delman¹, Priti Balchandani¹, and Rafael O'Halloran¹

¹Radiology, Icahn School of Medicine at Mount Sinai, New York, NY, United States, ²Wake Forest University, Winston-Salem, NC, United States, ³Neurology, Icahn School of Medicine at Mount Sinai, New York, NY, United States

The present study aims to identify the connectivity of the seizure onset zone (SOZ) in patients with MRI-negative epilepsy. Motivated by recent findings of aberrant white matter structure in epilepsy we hypothesized differences in structural connectivity. To test this we compared structural connectivity in a group of 8 epilepsy subjects and 8 healthy controls. We also investigated differences in connectivity in SOZ and non-SOZ areas in the epilepsy group. Hyper-connectivity was found in epilepsy subjects compared to controls. Additionally, hyper-connectivity was found in SOZ compared to non-SOZ related regions. These findings may have implications for diagnosis and surgical intervention in MRI-negative epilepsy.

High-Throughput Diffusion Imaging Using Multiple Coils for Mouse Brain Connectomics

John Nouls^{1,2}, Alexandra Badea^{1,2}, Robert J. Anderson^{1,2}, Gary P. Cofer^{1,2}, and G. Allan Johnson^{1,2}

¹Center for In Vivo Microscopy, Duke University Medical Center, Durham, NC, United States, ²Radiology, Duke University Medical Center, Durham, NC, United States

The complex neural architecture and brain connectivity of mouse models of human disease can be studied *ex vivo* by diffusion tensor imaging; however, acquisition times are long and make cohort studies prohibitively time-consuming. Throughput can be increased by the simultaneous use of multiple coils placed in proximity to the magnet isocenter. We quantify the impact of the multiple-coil configuration on throughput, on diffusion metrics used in tractography, and on mouse brain connectivity matrices. We show that fractional anisotropy is underestimated off-isocenter, while the main eigenvector direction is minimally affected. The effect on brain connectivity networks is currently being quantified.

Prediction vision recovery of Neuromyelitis optica spectrum disorders (NMOSDs) with multivariate pattern analysis: a DTI study

Yuan Tian¹, Lin Ma¹, Zhenyu Liu², Zhenchao Tang³, Xin Lou, Jie Tian, and Mingge Li

¹radiology department, Chinese PLA General Hospital, Beijing, People's Republic of China, ²Key Laboratory of Molecular Imaging, Institute of Automation, Chinese Academy of Sciences, ³School of Mechanical, Electrical & Information Engineering, Shandong University

To explore if a DTI protocol could provide a model to predict the degree of vision recovery in NMOSDs patients. 37 patients were employed in the study, including 20 patients of well vision recovery and 17 patients of poor vision recovery. With the diffusion measure of multiple white and grey matters as features, a Lasso-Logistic regression model and a Support Vector Machine (SVM)-based classification model were constructed. The results show area under curve (AUC) of 0.7618 (P=0.008) and accuracy (ACC) of 0.7297 (0.006). The method shows promising prediction performance, and it has the potential to improve the clinical treatment design.

White Matter Fiber Tractography with Fiber Ball Imaging

Hunter Moss¹, George Russell Glenn¹, Emilie T. McKinnon¹, and Jens Jensen¹

¹Medical University of South Carolina, Charleston, SC, United States

An investigation into the minimum b-value necessary to characterize the fiber orientation density function (fODF) with fiber ball imaging (FBI) for white matter fiber tractography (WMFT) is presented. Using high angular resolution diffusion imaging (HARDI) data, we assessed the angular difference between principal directions across b-values using a high b-value benchmark, as well as the number of fiber crossings based on fODF peak detection. WMFT was performed using the reconstructed fODFs and was viewed qualitatively. Overall, the results indicated convergence near $b = 4000 \text{ s/mm}^2$ suggesting this to be the minimum b-value needed for FBI-WMFT.

3488

Computer 39

Impact of white-matter hyperintensities on tractography

Guillaume Theaud¹, Bixente Dilharreguy², Gwénaëlle Catheline², and Maxime Descoteaux¹

¹Sherbrooke Connectivity Imaging Lab (SCIL), Université de Sherbrooke, Sherbrooke, QC, Canada, ²INCLIA, UMR 5287, Université de Bordeaux, EPHE PSL Research University, Talence, France

A common way to seed tractography is thresholding the Fractional Anisotropy (FA). This technique is problematic for aging diffusion MRI studies because the FA decreases dramatically in regions of White Matter Hyperintensities (WMH) and thus, the tractography can erroneously start or stop in these WMH regions. We show the importance for tractography pipelines to correct for WMH in their tracking masks. We show that the non-correction can lead to approximately 15% erroneous streamlines, which are false connections that can pollute the structural connectome and lead to misinterpretations.

3489

Computer 40

Effect of Different Seeding Strategies on Tractometry Reproducibility

Martin Cousineau^{1,2}, Maxime Descoteaux¹, and Hiromasa Takemura^{2,3}

¹Sherbrooke Connectivity Imaging Laboratory (SCIL), Université de Sherbrooke, Sherbrooke, QC, Canada, ²Center for Information and Neural Networks (CiNet), National Institute of Information and Communications Technology (NICT), Suita, Japan, ³Graduate School of Frontier Biosciences, Osaka University, Suita, Japan

Two common approaches to tractography seeding are using the whole-brain white matter mask, or the gray and white matter interface. Using a dataset with two acquisitions per subject and a state of the art processing pipeline, we compared the test-retest reproducibility of the shape and tract profiles of major white matter bundles for both seeding strategies. We found that both seeding strategies have regions in the brain where they are more reproducible. We propose an ensemble method combining both strategies as a possible way to make tractometry from white matter bundles more robust.

Tract covariance networks in expert dancers and pianists

Hsien-Te Su¹, Pin-Yu Chen², Yu-Jen Chen¹, Yung-Chin Hsu¹, Wei-Chi Li³, Tzu-Yi Hong³, Li-Fen Chen^{3,4}, Jen-Chuen Hsieh^{3,4}, and Wen-Yih Isaac Tseng^{1,5}

¹Institute of Medical Device and Imaging, National Taiwan University College of Medicine, Taipei, Taiwan, ²Department of Life Science, National Taiwan University, Taipei, Taiwan, ³Institute of Brain Science, National Yang-Ming University, Taipei, Taiwan, ⁴Integrated Brain Research Unit, Division of Clinical Research, Department of Medical Research, Taipei Veterans General Hospital, Taipei, Taiwan, ⁵Molecular Imaging Center, National Taiwan University, Taipei, Taiwan

To investigate plasticity of white matter tracts in expert dancers and pianists, we used diffusion spectrum imaging to measure generalized fractional anisotropy (GFA) of 76 major white matter tracts. A novel metric called tract covariance was defined as the correlation between each pair of tracts in variations of the mean GFA values across subjects. As compared with control subjects, expert dancers showed overall enhancement of the tract covariance, whereas expert pianists showed enhancement specific to sensory-motor processing. The findings underline the different effects on white matter tract plasticity following different types of long-term training.

On Quantitatively Comparing Tractography Algorithms

Birkan Tunç¹, Drew Parker¹, and Ragini Verma¹

¹University of Pennsylvania, Philadelphia, PA, United States

Systematic comparison of tractography algorithms is rendered challenging by the differences in diffusion models and multiple parameters. In this work, we have defined a statistical framework to compare tractography algorithms, from two different perspectives: (1) the volume of generated tracts and (2) number of unbroken fibers. We applied our framework to compare six algorithms (four using tensor model and two using HARDI model) in reconstructing the contralateral corticospinal tract in ten brain tumor patients. Our results demonstrated significant differences between algorithms. These experiments establish our tractography comparison framework which can be used by researchers and tractography challenges for quantitative comparison.

3495

Computer 46

Inferior Fronto-occipital Fasciculus Tractography — a Comparison of Reconstruction Methods

Ting Gong¹, Qiqi Tong¹, Hongjian He¹, Qiuping Ding¹, and Jianhui Zhong¹

¹Center for Brain Imaging Science and Technology, Department of Biomedical Engineering, Zhejiang University, Hangzhou, People's Republic of China

The anatomical definition and functional role of inferior fronto-occipital fascicle (IFOF) in human brain are important but still controversial. Post-mortem dissection has provided detailed and extended cortical terminations of IFOF while diffusion tractography further facilitates the definition of extended terminations through in vivo studies. A careful comparison of fiber reconstruction methods including diffusion tensor imaging, q-ball imaging, generalized q-sampling imaging and diffusion kurtosis imaging (DKI) was conducted. More integrated IFOF tracts were found with DKI, which could benefit the exploration of precise terminations of IFOF, thus a better understanding of its function.

3496

Computer 48

Important new insights for the reduction of false positives in tractograms emerge from streamline-based registration and pruning.

Tingyi Wanyan¹ and Eleftherios Garyfallidis¹

¹Intelligent Systems Engineering, Indiana University, Bloomington, IN, United States

Tractograms have large number of false positives. One possible solution is to use anatomically relevant atlases of bundles to create priors of known bundles and therefore concentrate on the true positives. However this requires registration with incomplete atlases that contain only a few known bundles. A new asymmetric cost function extensively advances the direct registration of tractograms to atlases with a small number of bundles. Furthermore, although existing ROI filtered atlases can miss important parts of bundles, by using a pruning method using streamline centroids, these parts can be found, and the false positives can be extensively reduced.

Comprehensive Correction of Motion and Nyquist Ghost Artifacts for Multi-shot Diffusion Imaging
Merry Mani¹, Mathews Jacob², Baolian Yang³, and Vincent Magnotta¹

¹Department of Radiology, University of Iowa, Iowa City, IA, United States, ²Department of Electrical and Computer Engineering, University of Iowa, Iowa City, IA, United States, ³GE Healthcare

Echo planar imaging data are often corrupted by Nyquist ghost artifacts resulting from the eddy current induced shifts between the odd & even phase encodes. Current EPI methods often rely on calibration scans that are collected prior to the data acquisition to correct for Nyquist ghosts. Unfortunately, this approach is often insufficient for the recovery of diffusion-weighted (DW) data, since the ghosting artifacts also depend on the segmentation of the EPI read-outs and diffusion weighting. We introduce a comprehensive algorithm to simultaneously correct for the eddy-current errors as well as the motion-induced artifacts in DW images that does not require any calibration scans.

3499

Computer 50

Motion-tolerance Single-scan Diffusion Mapping

Lingceng Ma¹, Congbo Cai², Zhong Chen¹, Shuhui Cai¹, Hongyi Yang³, and Kai Zhong³

¹Department of Electronic Science, Department of Electronic Science, Xiamen University, Xiamen, People's Republic of China, ²Department of Communication Engineering, Department of Communication Engineering, Xiamen University, Xiamen, People's Republic of China, ³High Magnetic Field Laboratory, High Magnetic Field Laboratory, CAS, Hefei, People's Republic of China

A new diffusion imaging method, single-scan diffusion mapping through overlapping-echo detachment planar (DM-OLED) imaging sequence with corresponding separation algorithm, was proposed. The method can get reliable diffusion mapping by a single-scan in about 120ms. The diffusion mapping gained by DM-OLED has immunity to motion and higher time resolution compared with conventional multi-scan diffusion methods. Experimental results of mouse brains verified the accuracy and the motion-tolerance of DM-OLED. As a reliable fast diffusion measurement tool, DM-OLED can be boded well for further uses in clinical real-time measurements.

Improved Detection of Spinal Cord Injury in Rats with Reduced Field of View (rFOV) and Orthogonal Filter-Probe (OFP) Diffusion Weighted Imaging (DWI)

Nathan Skinner^{1,2}, Shekar Kurpad^{3,4}, Brian Schmit⁵, L. Tugan Muftuler³, and Matthew Budde³

¹Biophysics Graduate Program, Medical College of Wisconsin, Milwaukee, WI, United States, ²Medical Scientist Training Program, Medical College of Wisconsin, Milwaukee, WI, United States, ³Neurosurgery, Medical College of Wisconsin, Milwaukee, WI, United States, ⁴Clement J Zablocki Veterans Affairs Medical Center, Milwaukee, WI, United States, ⁵Biomedical Engineering, Marquette University, Milwaukee, WI, United States

To improve image quality for investigation of spinal cord injury, a reduced field of view excitation scheme was implemented on a Bruker 9.4T imaging system. This was combined with an optimized orthogonal filter-probe diffusion weighted imaging sequence to improve specificity for axonal injury with a short acquisition time. Application in a rat spinal cord injury model showed sensitive detection of diffusivity changes 48 hours post-injury with improved image quality compared to a standard full field of view acquisition. These advances provide support for this technique as a potential biomarker of injury severity with the ability for translation into clinical systems.

Whole-brain diffusional variance decomposition (DIVIDE) in 8 minutes: Technical feasibility at 1.5, 3, and 7 T

Filip Szczepankiewicz¹, Jens Sjölund^{2,3,4}, Freddy Ståhlberg^{1,5,6}, Jimmy Lätt⁷, and Markus Nilsson^{5,6}

¹Medical Radiation Physics, Lund University, Lund, Sweden, ²Elekta Instrument AB, Kungstensgatan 18, Box 7593, SE-103 93 Stockholm, Stockholm, Sweden, ³Department of Biomedical Engineering, Linköping University, Linköping, Sweden, ⁴Center for Medical Image Science and Visualization, Linköping University, Linköping, Sweden, ⁵Department of Clinical Sciences Lund, Lund University, Skåne University Hospital, Lund, Sweden, ⁶Lund University Bioimaging Center, Lund University, Lund, Sweden, ⁷Department of Imaging and Function, Skåne University Hospital, Lund, Sweden

Diffusion weighting along more than one direction at a time (tensor-valued encoding) can be used to probe features of the microstructure that are not accessible by conventional encoding. For example, it enables diffusional variance decomposition (DIVIDE) which can separate the effects of microscopic anisotropy, orientation dispersion, and heterogeneous isotropic diffusivity. Tensor-valued encoding is usually demanding with respect to gradient performance, limiting its applicability to high-performance MRI systems. However, a recent method for optimized encoding significantly reduced the demand on gradient performance, which warrants an investigation of the applicability of such encoding on a wider range of MRI hardware configurations. In this study, we demonstrate whole-brain diffusional variance decomposition (DIVIDE) in less than 8 minutes at a wide range of clinical MRI systems with different hardware configurations.

Compressed sensing diffusion spectrum imaging as a forward-looking alternative to multi-shell diffusion MRI in population imaging
Alexandra Tobisch¹, Rüdiger Stirnberg¹, Robbert Leonard Harms², Thomas Schultz³, Alard Roebroek², Monique Breteler¹, and Tony Stöcker¹

¹German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany, ²Faculty of Psychology & Neuroscience, Maastricht University, Maastricht, Netherlands, ³University of Bonn, Institute of Computer Science, Bonn, Germany

This study investigates the applicability of two advanced diffusion MRI protocols in population imaging: 3-shell High Angular Resolution Diffusion Imaging (HARDI) and Diffusion Spectrum Imaging accelerated through Compressed Sensing theory (CS-DSI). Group analysis of 20 subjects indicates that CS-DSI performs comparable to 3-shell HARDI in the estimation of microstructure parameters and adds the advantage of high b-value acquisitions, further complimentary biomarkers from the diffusion propagator and a high potential to deliver data well-suited for future developments.

Quantitative Noise Analysis for Increased Homogeneity in Intra-voxel Incoherent Motion (IVIM) Perfusion Imaging in Brain

Harri Merisaari^{1,2} and Christian Federau³

¹Turku PET Centre, Turku University Central Hospital, Turku, Finland, ²Department of Information Technology, University of Turku, Turku, Finland, ³Department of Radiology, Uniklinik Balgrist, University Zürich, Zürich, Switzerland

Intravoxel incoherent motion (IVIM) perfusion imaging has been shown to be applicable in clinical brain examinations, but those images are known to be noisy. To better quantify the necessary conditions to produce homogenous IVIM perfusion images in the brain, we studied the properties of signal noise as function of b-value and of localization in the brain. We compared the image quality of the perfusion maps as function of number of average to the maximal quality IVIM perfusion maps obtained during a 1 hour acquisition time.

Computer 57

High Resolution Cervical Spine Single-Shot DTI with Distortion Correction Using Modified Field-mapping Method

Yuhui Xiong¹, Xiaodong Ma¹, Zhe Zhang¹, Yishi Wang¹, and Hua Guo¹

¹Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China

Single-shot echo planar imaging (EPI) DTI (SS-DTI) has been commonly used in clinical cervical spine (C-spine) MR scans to get functional and pathologic information as it's fast and straightforward, but high resolution SS-DTI image suffers from severe geometric distortion. Field mapping method is a classical and simple distortion correction technique, but its performance in C-spine SS-DTI is limited. We used echo planar spectroscopic imaging (EPSI) sequence to acquire the field-map, and modified the conventional field-map post-processing method to promote the correction efficacy. The results show that the proposed method is effective and fast in C-spine SS-DTI distortion correction.

Computer 58

High b-value Diffusion-Weighted MRI for Detection of Interscapular Brown Adipose Tissue in Rodent Model

Weiguo Li^{1,2,3}, Jin Gao³, Andrew Gordon², Kejia Cai⁴, Andrew Larson², and Richard Magin³

¹Research Resource Center, University of Illinois at Chicago, Chicago, IL, United States, ²Radiology, Northwestern University, Chicago, IL, United States, ³Bioengineering, University of Illinois at Chicago, Chicago, IL, United States, ⁴Radiology, University of Illinois at Chicago, Chicago, IL, United States

Brown adipose tissue (BAT) is increasingly considered a target organ for the treatment of metabolic disease. Persuasive evidence has shown that enhancement of the function of brown and beige adipocytes in humans could be very effective for treating type 2 diabetes and obesity. However, clinical studies have been limited by the lack of non-invasive tools for characterizing this tissue in humans. In this study, we explored the feasibility of using high b-value diffusion-weighted MRI for detecting the distribution of interscapular brown adipose tissue.

Free-water elimination in diffusion MRI: pushing the limits towards clinical applications

Ezequiel Farrher¹, Farida Grinberg^{1,2}, Zaheer Abbas^{1,2}, and N. Jon Shah^{1,2,3}

¹Institute of Neuroscience and Medicine 4, Forschungszentrum Jülich, Jülich, Germany, ²Department of Neurology, Faculty of Medicine, RWTH Aachen University, Aachen, Germany, ³JARA – BRAIN – Translational Medicine, RWTH Aachen University, Aachen, Germany

Free-water elimination allows one to reduce the bias in DTI metrics induced by partial-volume effects. In this work, we propose a versatile approach for the optimisation of the diffusion weighting settings, given a limited acquisition time, based on a parameterised Cramér-Rao lower-bound. The optimisation shows robust convergence.

3509

[Assessing the Effect of Intravoxel Incoherent Motion on Diffusion Parameters in the Brain](#)

Casey Robert Vieni^{1,2}, Benjamin Ades-Aron¹, Bettina Conti¹, Timothy M Shepherd¹, Yvonne W Lui¹, Dmitry Novikov¹, and Els Fieremans¹

¹*Bernard and Irene Schwartz Center for Biomedical Imaging, Department of Radiology, New York University School of Medicine, New York University, New York, NY, United States*, ²*Medical Scientist Training Program, New York University School of Medicine, New York, NY, United States*

We investigated the effect of intravoxel incoherent motion (IVIM) on the brain diffusion MRI signal in a cohort of 143 control patients. We compared the diffusivities derived from a mono-exponential fit at $b = 0$ and $1 \text{ ms}/\mu\text{m}^2$ versus at $b = 0.25$ and $1 \text{ ms}/\mu\text{m}^2$. This allowed for a quantitative assessment of the IVIM signal fraction f^* in specific brain matter types. Our results show a significant difference in the mean diffusivity of about 3% in white matter and up to 7% in grey matter, with corresponding f^* estimated to be about 2% and 6% in white and grey matter respectively.

Computer 61

[Design of a locally incoherent sampling scheme for improved joint k-q reconstruction of diffusion MRI](#)

Wenchuan Wu¹, Peter J Koopmans¹, and Karla L Miller¹

¹*FMRI, University of Oxford, Oxford, United Kingdom*

For joint k-q reconstruction, it's beneficial to incoherently under-sampling k-space for different q-space points to utilize the complimentary k-space information. As nearby q-space points in general share more similarities than distant points, it is hypothesized that locally-incoherent k-space sampling can further improve the joint k-q reconstruction. In this work, we propose a method to design locally-incoherent k-space sampling patterns based on a graph colouring algorithm. Results show the proposed method achieves better reconstruction than existing sampling schemes.

3511

Computer 62

[Model-Based Reconstruction for Undersampled High Resolution Diffusion Tensor Imaging Combined with Simultaneous Multi-Slice Acquisitions](#)

Zijing Dong¹, Erpeng Dai¹, Fuyixue Wang^{1,2}, Yuantao Gu³, Chun Yuan^{1,4}, and Hua Guo¹

¹*Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China*, ²*Harvard-MIT Health Sciences and Technology, MIT, Cambridge, MA, United States*, ³*Department of Electronic Engineering, Tsinghua University, Beijing, People's Republic of China*, ⁴*Vascular Imaging Laboratory, Department of Radiology, University of Washington, Seattle, WA, United States*

Multi-shot interleaved EPI is an effective method to acquire high-resolution and less distorted diffusion weighted images, but with relatively low acquisition efficiency, especially for diffusion tensor imaging. Here, a novel model-based reconstruction is proposed for accelerated multi-shot diffusion imaging with simultaneous multi-slice (SMS) and partially parallel imaging (PPI). The method can directly estimate diffusion tensors from the undersampled k-space data, by integrating information of all shots and diffusion encoding directions. Simulation and in-vivo experiment demonstrated that the proposed method can achieve higher acceleration efficiency and improved accuracy in tensor estimation compared with conventional 2D GRAPPA.

3512

Computer 63

[Accelerated High Resolution EPI DTI Using Model-Based Reconstruction](#)

Zijing Dong¹, Fuyixue Wang^{1,2}, Zhe Zhang¹, Erpeng Dai¹, Xiaodong Ma¹, Yuantao Gu³, and Hua Guo¹

¹*Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China*, ²*Harvard-MIT Health Sciences and Technology, MIT, Cambridge, MA, United States*, ³*Department of Electronic Engineering, Tsinghua University, Beijing, People's Republic of China*

Single-shot EPI is the most widely used sequence in diffusion tensor imaging. However, severe distortion in single-shot EPI limits its application for higher resolution images. Multi-shot EPI DTI can reduce distortion but results in longer acquisition time especially when a large number of diffusion-encoding directions are used. Here, we propose a model-based reconstruction framework for EPI DTI to estimate diffusion tensors from undersampled EPI sequences, in order to achieve high resolution diffusion imaging in a shorter scan time. The effectiveness of the proposed model-based method to get precise tensor estimation is validated by DTI simulation and in-vivo experiments.

3513

Computer 64

[Quantification of Navigator Requirements for Multi-shot Diffusion Weighted Imaging](#)

Joseph L Holtrop¹ and Bradley P Sutton¹

¹*Bioengineering, University of Illinois at Urbana-Champaign, Urbana, IL, United States*

The ability to use multiple shots in diffusion weighted imaging has enabled acquisitions with higher resolutions and higher SNRs. The methods currently being used to achieve higher resolutions rely on navigator information to correct for mismatches in coherent motion during the diffusion encoding between shots. The resolution of the navigator is a critical factor, too low and the corrections are incomplete, too high and there is a significant time or echo time penalty. This work presents an analysis for determining the resolution requirements for navigation. This work found that using a navigator resolution of 6 mm produces reliable results and allows shorter acquisitions to be used.

3514

Computer 65

[Accelerated Body nCPMG SS-FSE Diffusion Weighted Imaging](#)

Eric Kenneth Gibbons¹, Patrick LeRoux², Shreyas Vasanawala³, John Mark Pauly⁴, and Adam Bruce Kerr⁴

¹Department of Bioengineering, Stanford University, Stanford, CA, United States, ²Praxidemia Libra, Palaiseau, France, ³Department of Radiology, Stanford University, Stanford, CA, United States, ⁴Department of Electrical Engineering, Stanford University, Stanford, CA, United States

This abstract presents a novel reconstruction for the nCPMG SS-FSE sequence. A theoretical justification for this approach is given. This reconstruction and sequence is demonstrated in phantom and *in vivo* and is shown to be quantitatively and qualitatively robust.

3515

Computer 66

Feasibility of very high b-value diffusion imaging using a clinical scanner.

Steen Moeller¹, Essa Yacoub¹, Sudhir Ramanna¹, Emily Kittelson¹, Kamil Ugurbil¹, and Christophe Lenglet¹

¹Center for Magnetic Resonance Research, Minneapolis, MN, United States

The use of locally low-rank matrix approximation methods for noise variance reduction provides a powerful tool for diffusion MRI to increase the quality of very high b-value acquisitions. Using a clinical system, we demonstrate the feasibility of multi-shell high angular resolution diffusion imaging with b-value up to 10,000s/mm².

Computer 67

Multiband IRIS: A framework for diffusion-weighted image reconstruction integrating multiband, multishot, SENSE and 2D navigated motion correction

Ha-Kyu Jeong¹

¹Philips Korea, Seoul, Korea, Republic of

IRIS has been proposed for diffusion-weighted (DW) image reconstruction with 2D-navigated motion correction from highly aliased DW-MRI data using multishot and regularly subsampled SENSE implementations simultaneously. In this work, it is demonstrated that IRIS framework can be extended for multiband DW image reconstruction for reconstructing motion-free multiband multishot DW images.

3517

Computer 68

eIRIS — An Eigen-Analysis Motivated Approach for More Robust Multi-Shot Diffusion-Weighted Imaging

Li Guo¹, Zhongbiao Xu¹, Yingjie Mei^{1,2}, Wenxing Fang³, Chenguang Zhao³, Wufan Chen¹, Yanqiu Feng¹, and Feng Huang⁴

¹Guangdong Provincial Key Laboratory of Medical Image Processing, School of Biomedical Engineering, Southern Medical University, Guangzhou, People's Republic of China, ²Philips Healthcare, Guangzhou, People's Republic of China, ³Philips Healthcare (Suzhou), Suzhou, People's Republic of China, ⁴Neusoft Medical System, Shanghai, People's Republic of China

IRIS corrects the motion-induced inter-shot phase errors for multi-shot diffusion-weighted imaging by extracting the phase information from an additional navigator data, which may cause the distortion mismatch between the image and navigator data. To solve the distortion mismatch issue in IRIS without using B₀ field map, we propose to extract the coil sensitivities and phase information from navigator data by using an eigen-analysis scheme. The performance of the proposed method is demonstrated in both phantom and *in vivo* data sets.

Computer 69

Accelerating Diffusion Tensor Imaging Using a Parametric Manifold Model

Chaoyi Zhang¹, Dan Wu², Jiangyang Zhang³, Dong Liang⁴, Jingyuan Lyu¹, Ukash Nakarmi¹, Rong-Rong Chen⁵, and Leslie Ying^{1,6}

¹Electrical Engineering, University at Buffalo, State University of New York, Buffalo, NY, United States, ²Radiology, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ³Radiology, New York University School of Medicine, New York City, NY, United States, ⁴Biomedical and Health Engineering, Shenzhen Institutes of Advanced Technology, Shenzhen, People's Republic of China, ⁵Electrical & Computer Engineering, University of Utah, Salt Lake City, UT, United States, ⁶Biomedical Engineering, University at Buffalo, State University at New York, Buffalo, NY, United States

This abstract presents a novel method for diffusion tensor image (DTI) directly from highly under-sampled data acquired at multiple diffusion gradients. This method formulates the diffusion tensor estimation as a problem of parametric manifold recovery. We solve the recovery problem by alternatively shrinking the diffusion weighted images, estimating diffusion tensor, and enforcing data consistency constraint. The experimental results demonstrate that the proposed method is able to reconstruct the diffusion tensors accurately at high acceleration factors with low computational complexity.

High Spatial Resolution White Matter Fibrography (WMF): Technique Optimization

Hernan Jara¹, Osamu Sakai¹, Stephan W Anderson¹, and Jorge A Soto¹

¹Boston University, Boston, MA, United States

Purpose: To test the high spatial resolution limits of the white matter fibrography (WMF) technique within the scan time constrains of clinical MRI of about ten minutes total scan time and to optimize the image processing algorithms for rendering the white matter (WM) connectome at the highest level of anatomic detail. Methods: Healthy volunteer was scanned with the quadra-FSE pulse at high spatial resolution in 10min. Results: WMF connectome was constructed using ultra-high b-value (34,000s/mm²) synthetic MRI. Conclusion: High spatial resolution direct rendering of the human brain connectome can be accomplished with a 10min scan.

Comparing the LPCA and MPPCA denoising approaches for diffusion MRI using simulated human data

Qiuting Wen¹, Mark S. Graham², Sourajit M. Mustafi¹, Ivana Drobnjak², Hui Zhang², and Yu-Chien Wu¹

¹Indiana University, Indianapolis, IN, United States, ²University of College London

In this study, we investigate two denoising methods for diffusion MRI: the local PCA approach and Marchenko-Pastur (MP) PCA approach. Ground-truth diffusion-weighted images of the human brain are developed and used for noise simulation. Two diffusion-weighting b-values and two noise levels are generated as input data for both denoisers. Metrics of diffusion tensor imaging (DTI) and neurite orientation distribution and density (NODDI) are computed after denoising and compared between denoise methods.

Quantitative assessment of susceptibility artefact correction techniques for diffusion-weighted MRI

Mark S Graham¹, Ivana Drobnjak¹, and Hui Zhang¹

¹Centre for Medical Image Computing and Department of Computer Science, University College London, London, United Kingdom

It is necessary to correct for susceptibility artefacts in DW-MR, but there are a number of available strategies to choose from. In this work we apply a simulation framework, previously used to assess motion and eddy current correction strategies, to quantitatively evaluate methods for susceptibility correction. Our results indicate that methods that use reversed phase-encoding data perform the best. Furthermore they show that non-linear registration of diffusion data to a structural target in insufficient to fully correct for the susceptibility artefact.

Multi-contrast diffeomorphic non-linear registration of orientation density functions

Maximilian Pietsch¹, David Raffelt², Thijs Dhollander², and J-Donald Tournier¹

¹Centre for the Developing Brain, Division of Imaging Sciences and Biomedical Engineering, King's College London, London, UK, London, United Kingdom, ²Florey Institutes of Neuroscience and Mental Health, Melbourne, Australia

Spatial normalisation of high angular resolution diffusion images (HARDI) is an important prerequisite for group-level analysis of tissue microstructure. In this study, we extend a technique for non-linear registration of orientation density functions by including other non-WM tissue types into the metric driving the registration, and investigate the benefits this provides in terms of overall alignment. Our results show that including additional non-WM tissue types in the registration metric improves the performance of the registration, as assessed by visual inspection (sharper features), and in simulations (slight reduction in residuals)

Diffusion Kurtosis Imaging with the breath hold method for staging of hepatic fibrosis: Potential as additional sequence in a clinical routine

Daisuke Yoshimaru^{1,2}, Toshiaki Miyati², Yuichi Suzuki³, Yuhki Hamada¹, Nozomi Mogi⁴, Ayumu Funaki¹, Ayumi Tabata¹, Maki Tobar⁵, and Takayoshi Nishino⁵

¹Department of Medical Technology Image Laboratory, Tokyo Women's Medical University Yachiyo Medical Center, Yachiyo, Japan, ²Division of Health Sciences, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, Ishikawa, Japan, ³Department of Radiological Service, The University of Tokyo Hospital, Japan, ⁴Department of Radiological Service, Tokyo Women's Medical University Medical Center East, Japan, ⁵Department of gastroenterological medicine, Tokyo Women's Medical University Yachiyo Medical Center, Yachiyo, Japan

We evaluated hepatocellular degeneration using DKI analysis with the breath hold technique compared with the pathological appearance about chronic hepatic diseases and hepatic fibrosis. Using this DKI method in the liver the stage of hepatic fibrosis can be classified into normal hepatic fibrosis and early hepatic fibrosis, and into early hepatic fibrosis and advanced hepatic fibrosis. Thus, we consider that DKI analysis can reflect pathological classification accurately. We consider that this DKI method will be required to evaluate the degree of hepatic fibrosis and to monitor the progress of hepatic fibrosis as an additional sequence in a clinical routine.

SHANK-3 gene mutation results in comprehensive white matter damage in children: a DTI-TBSS study
Dongyun Li¹, Chunxue Liu¹, Xiu Xu¹, Ed X. Wu², and Zhongwei Qiao¹

¹Children's Hospital of Fudan University, Shanghai, People's Republic of China, ²Laboratory of Biomedical Imaging and Signal Processing, The University of Hong Kong, HongKong, Hong Kong

Autism spectrum disorder (ASD) is classified as a neuro-developmental disease with a dramatically increasing prevalence from 4 in 10000 to recently 1 in 68 children. SHANK-3 proteins are multidomain scaffold proteins of the postsynaptic density and also play a role in synapse formation and dendritic spine maturation. Recent human genetic studies suggest the potential association between molecular defects of SHANK-3 and ASD. DTI imaging and TBSS analysis was applied to study how SHANK-3 gene mutation results in severe microstructure of white matter. Results showed significant damage in SHANK-3 group but no positive findings between ASD and typical development controls. These results calls for attention to re-examine the previous neuroimaging studies of ASD or other neuro-developmental diseases where the positive correlations could be contaminated with unexplored genetic mutation influence.

Brain correlates of apathy in Kleine Levin syndrome: a mean apparent propagator study

ANNE-CHARLOTTE PHILIPPE¹, LAVALT SOPHIE², FICK RUTGER³, WASSERMANN DEMIAN³, VALABREGUE ROMAIN¹, DERICHE RACHID³, LEVY RICHARD², ARNULF ISABELLE², and LEHERICY STEPHANE¹

¹Institut Cerveau Moelle – ICM, CENIR, ICM, Inserm – UPMC U1127, CNRS 7225, Paris, France, ²Service des pathologies du sommeil, Hôpital de la Pitié Salpêtrière, France, ³Université Côte d'Azur, INRIA, France

Kleine-Levin syndrome (KLS) is a rare neurological disorder characterized by episodes of severe hypersomnia, apathy, cognitive impairment, derealization and behavioral disturbances. Between episodes, patients have normal sleep, mood and behavior. Apathy is a prominent clinical feature of KLS but its pathophysiology is not known. Here we used mean apparent propagator to investigate white matter changes in KLS and correlated diffusion changes with apathy scores. Results showed that the corpus callosum was involved in KLS during episodes and mean RTAP measures in the corpus callosum correlated with apathy scores. Results were in accordance with known motivation-based circuits involving the orbitomedial frontal cortex.

A unified framework for upsampling and denoising of diffusion MRI data

Samuel St-Jean¹, Max Viergever¹, and Alexander Leemans¹

¹Image Sciences Institute, University Medical Center Utrecht, Utrecht, Netherlands

Diffusion MRI suffers from relatively long scan times and low signal to noise ratio (SNR), which limits the acquired spatial resolution. In this work, we propose a unified framework for denoising and upsampling diffusion datasets based on a sparse representation of the diffusion signal. Our proposed method shows less blurring and increased anatomical details in the pons region when compared to denoising and subsequent spline interpolation. At the junction of the corpus callosum, the corticospinal tract and the cingulum, finer structures are also preserved as evidenced by a high resolution *in vivo* acquisition.

3534

Computer 88

Investigating the adverse effect of gradient nonuniformities on diffusion MRI measures: Do we need to worry?

Hamed Y. Mesri¹, Martijn Froeling², Max A. Viergever¹, Anneriet M. Heemskerk¹, and Alexander A. Leemans¹

¹Image Sciences Institute, University Medical Center Utrecht, Utrecht, Netherlands, ²Department of Radiology, University Medical Center Utrecht, Utrecht, Netherlands

Nonuniformities of gradient magnetic fields in diffusion-weighted MRI can introduce systematic errors in estimates of diffusion measures. While there are correction methods that can compensate for these errors, as presented in the Human Connectome Project, such non-linear effects are assumed to be negligible for typical applications and, hence, gradient nonuniformities are mostly left uncorrected. In this work, we evaluated the effect of ignoring such diffusion gradient nonuniformities on measures derived from diffusion tensor imaging. In particular, we simulated deviations from the ground-truth in terms of b-value and diffusion gradient orientation and investigated the resulting bias in fractional anisotropy and orientation of the first eigenvector. Our results demonstrate that not including a correction strategy to mitigate diffusion gradient imperfections especially for high quality data may lead to a significant bias for diffusion measure estimates.

3535

Computer 89

MuSHER: Multi-shell Spherical Harmonic Error Rejection

Greg Daniel Parker¹ and Derek K Jones¹

¹Cardiff University, Cardiff, United Kingdom

Diffusion weighted imaging is prone to artefacts. Sources including hardware instability, bulk motion and cardiac pulsation can all induce spurious signal intensities (i.e. corruption) which negatively affect derived measurements. To combat this an additional processing step may be added to detect (and subsequently reject) such corrupted data points; however, with the increasing use of multi-shell acquisitions a number of existing approaches (constrained to a single b-value shell and/or unsuitable diffusion tensor models) are no longer applicable, limiting available choices. With this abstract we propose a new multi-shell detection algorithm and provide preliminary experimental results.

Computer 91

The Neonatal DTI fiber atlas for studies of brain development at birth

Rachel J Steiner^{1,2}, Sarah J Short³, Rebecca Knickmeyer Santelli³, Audrey Rose Verde³, Aditya Gupta³, François Budin⁴, Katherine A Gilmore³, Nagesh Adluru⁵, Guido Gerig⁶, John H Gilmore³, and Martin A Styne^{3,7}

¹Center for Investigating Healthy Minds, University of Wisconsin-Madison, Madison, WI, United States, ²Psychology, University of Wisconsin-Madison, Madison, WI, United States, ³Psychiatry, University of North Carolina at Chapel Hill, ⁴Kitware Inc., ⁵Waisman Center, University of Wisconsin-Madison, ⁶Tandon School of Engineering, Department of Computer Science & Engineering, NYU, ⁷Department of Computer Science, University of North Carolina at Chapel Hill

Given the increasing popularity and wealth of DWI data in the field of neuroimaging, there is a critical need for the development of publically available resources that enable widespread application of a set of template fibers for atlas based along-tract analysis supporting an adequate and reliable analysis of DTI in newborns in both practice and in clinical research settings. To address this gap, we developed a Neonate DTI atlas that represents a typically developing human brain during the first few weeks of life. To the best of our knowledge, we are the first to develop a population atlas with this magnitude of quality and sample size, as well as with a comprehensive set of template fibers for semi-automatic tract based analysis. The DTI atlas and the tracts will be made available through NITRC.

3538

Computer 92

A fingerprinting approach to identifying fiber directions in Orientation Distribution Functions for Higher Order Diffusion MRI

Steven H. Baete^{1,2}, Ying-Chia Lin^{1,2}, and Fernando E. Boada^{1,2}

¹Center for Advanced Imaging Innovation and Research (CAI2R), NYU School Of Medicine, New York, NY, United States, ²Center for Biomedical Imaging, Dept of Radiology, NYU School Of Medicine, New York, NY, United States

High quality diffusion acquisitions are routinely used to study white matter architecture and brain connectivity in vivo. A key step for successful tractography of neuronal tracts is correct identification of the tract directions in each voxel. Here we propose a fingerprinting-based methodology for identifying these fiber directions in Orientation Distribution Functions. This ODF-fingerprinting approach improves the detection of fiber pairs with small crossing angles whilst maintaining fiber direction precision. This improvement will aid fiber tracking algorithms in accurately displaying neuronal tracts and calculating brain connectivity.

Non-Central Chi to Gaussian Transformation of Diffusion MRI Signals Improves Estimation of Fiber ODFs

Geng Chen¹, Dinggang Shen¹, and Pew-Thian Yap¹

¹Department of Radiology and BRIC, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Many existing algorithms for estimation of the fiber orientation distribution function (ODF) inherently assume Gaussian noise distribution. Against this assumption, the non-central chi noise distribution of diffusion signals causes bias in fiber ODF estimation. In this work, we introduce a means of transforming the diffusion-weighted signals to have a Gaussian noise distribution with the help of the recently introduced x - q space non-local means (XQ-NLM) algorithm. We show that this signal mapping improves estimation of fiber ODFs.

TORTOISE v3: Improvements and New Features of the NIH Diffusion MRI Processing Pipeline

Mustafa Okan Irfanoglu^{1,2,3}, Amritha Nayak^{1,2,3}, Jeffrey Jenkins^{1,2}, and Carlo Pierpaoli^{1,2}

¹Quantitative Medical Imaging Section, NIBIB/NIH, Bethesda, MD, United States, ²SQUITS/NICHHD/NIH, Bethesda, MD, United States, ³Henry Jackson Foundation, Bethesda, MD, United States

Here we present a series of improvements and new features of the TORTOISE diffusion MRI data processing software (www.tortoisedt.org). TORTOISEv3 has been programmed in C++ and it is now significantly faster, can be batched and it fully benefits from modern multi-core CPU architectures. The DIFFPREP module brings a multitude of new and state-of-art features including DWI denoising, Gibbs ringing removal, and the ability to perform motion and eddy currents distortion correction for very high b-value data. The new DIFFCALC module can perform MAP-MRI propagator estimation and the output can be easily imported in other software packages for statistical analysis and atlas creation.

Bias Field Correction and Intensity Normalisation for Quantitative Analysis of Apparent Fibre Density

David Raffelt¹, Thijs Dhollander¹, J-Donald Tournier², Rami Tabbara¹, Robert E Smith¹, Eric Pierre¹, and Alan Connelly¹¹Florey Institute of Neuroscience, Melbourne, Australia, ²Centre for the Developing Brain, Division of Imaging Sciences and Biomedical Engineering, Kings College London, London, United Kingdom

Apparent Fibre Density (AFD) is a measure derived from un-normalised fibre orientation distributions. To make AFD quantitative across subjects, images need to be intensity normalised and bias field corrected. Here we present a fast and robust approach to simultaneous bias field correction and intensity normalisation by exploiting tissue compartment maps derived from multi-tissue constrained spherical deconvolution. We performed simulations to show that the method can accurately recover a ground truth bias field, while also demonstrating qualitative results on *in vivo* data.

3542

Computer 96

Multi compartment deconvolution with L2 regularization and priors improves repeatability of MD estimation through free water and IVIM elimination.

Alberto De Luca^{1,2}, Filippo Arrigoni², Alessandra Bertoldo¹, and Martijn Froeling³¹Department of Information Engineering, University of Padova, Padova, Italy, ²Neuroimaging Lab, Scientific Institute IRCCS Eugenio Medea, Bosisio Parini (LC), Italy, ³Radiology Department, University Medical Center Utrecht, Utrecht, Netherlands

Pseudo continuous description of the diffusion MRI (dMRI) signal through multi-compartment deconvolution is a promising technique to disentangle different water pools in the brain. In this work we verified whether a deconvolution based approach with L₂ regularized priors could improve the repeatability of DTI metrics computed on the brain data of 3 volunteers acquired twice. Signal fractions of free water and perfusion could reliably be quantified and removed from the diffusion signal, improving the repeatability of MD estimation both in gray and white matter.

Comparing liver fat quantification obtained with Complex Chemical Shift-Encoded MRI and Conventional method in an oncologic population sample.

Alessandra Borgheresi¹, Davinia Ryan¹, Simone Krebs¹, Sarah Eskreis-Winkler¹, and Lorenzo Mannelli¹¹Radiology, Memorial Sloan Kettering Cancer Center, New York, NY, United States

Chemotherapy is hepatotoxic. Since steatosis is an early sign of hepatotoxicity, an accurate estimation of the changing of fat liver concentration would be useful in the management of oncologic patients. The purpose of this study was to compare fat liver concentration estimated by T1-weightened-in-and-out-of-phase (IOP) imaging with the one obtained by IDEAL-IQ method in an oncologic patients population with unknown liver iron concentration. A statistical difference was demonstrated between fat fraction estimated with conventional IOP imaging and IDEAL-IQ method.

Feasibility of computed diffusion-weighted MR imaging for visualization of pancreatic adenocarcinoma: comparison with acquired diffusion-weighted imaging

Yoshihiko Fukukura¹, Yuichi Kumagae¹, Hiroto Hakamada¹, Koji Takumi¹, Kiyohisa Kamimura¹, Masanoari Nakajo¹, Tomoyuki Okuaki², and Takashi Yoshiura¹¹Radiology, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan, ²Philips Electronics Japan, TN, Japan

We compared directly acquired diffusion-weighted imaging (DWI) at b-values of 1500 s/mm² and 2000 s/mm² with computed DWI (cDWI) at the same b-values, which was calculated from directly acquired DWI data at b-values of 0 s/mm² and 1000 s/mm². Our main result is that the incidence of clear hyperintense pancreatic adenocarcinomas was significantly higher on cDWI at a b-value of 1500 s/mm² than on directly acquired DWI at a b-value of 1000 s/mm² (P < 0.001) and was comparable to the incidence on directly acquired DWI at a b-value of 1500 s/mm², suggesting that cDWI to a b-value of 1500 s/mm² has diagnostic merit.

Hyperpolarized [1-13C]pyruvate reveals increase of hepatic LDH activity following a glucose challenge in pigs

Uffe Kjærgaard¹, Christoffer Laustsen¹, Thomas Nørting¹, Emmeli Mikkelsen¹, Rasmus Stilling Tougaard², Qi Haiyun¹, Lotte Bonde Bertelsen¹, Niels Jessen³, and Hans Stødkilde-Jørgensen¹¹MR Research Centre, Aarhus University Hospital, Aarhus, DK, Aarhus N, Denmark, ²Department of Cardiology – Research, Aarhus University Hospital, Aarhus, DK, ³Department of Clinical Medicine - Research Laboratory for Biochemical Pathology, Aarhus University, Aarhus, DK

Hepatic regulation of glucose homeostasis is of pivotal importance and thus *in vivo* interrogation of hepatic energetic alterations in disease and treatment non-invasively using [1-13C] pyruvate has been proposed as a novel modality for assessing metabolic status. Here we investigated the metabolic effect of a glucose challenge on the porcine liver. A hepatic metabolic shift towards a reduced gluconeogenesis (increased lactate pool size) was observed following the glucose challenge, confirming hyperpolarized ¹³C MR's ability to detect such changes. These findings support the use of hyperpolarized MR in metabolic challenge test in patients.

Stereotactic body radiation therapy with a simultaneous integrated boost (SBRT-SIB) has been used to improve tumor resection rate by sterilizing cancerous tissue that are surrounding the vessels. Accurate tumor imaging and tumor motion assessment will enhance the potential for SBRT-SIB. 4D-MRI (respiratory resolved, 3D volumetric images) has emerged as a promising imaging technique for characterizing tumor motion due to the absence of ionizing radiation and its superior soft tissue contrast. This study explored a slab-selective excitation approach to increase the blood vessel to tissue contrast with the goal of improving the accuracy of boost volume definition in radiation therapy.

PET/MR in pancreatic cancer: correlation between overall survival and functional imaging biomarkers from DCE-MRI, DWI, MR spectroscopy and PET

Bang-Bin Chen¹, Yu-Wen Tien², Ming-Chu Chang³, Mei-Fang Cheng⁴, Shih-Hung Yang⁵, and Tiffany Ting-Fang Shih^{6,7}

¹Department of Medical Imaging and Radiology, National Taiwan University Medical School and Hospital, Taipei, Taiwan, ²Department of Surgery, National Taiwan University Medical School and Hospital, ³Department of Internal Medicine, National Taiwan University Medical School and Hospital, ⁴Department of Nuclear Medicine, National Taiwan University Medical School and Hospital, ⁵Department of Oncology, National Taiwan University Medical School and Hospital, ⁶Department of Radiology, National Taiwan University Medical School and Hospital, Taipei, Taiwan, ⁷Department of Medical Imaging, Taipei City Hospital

The purpose of this study is to evaluate the association of imaging biomarkers from PET/MR with overall survival in pancreatic cancer patients. Sixty-four patients with pathologically-proven pancreatic adenocarcinoma underwent PET/MRI before treatment. The imaging biomarkers included Ktrans and Peak from DCE-MRI, minimal apparent diffusion coefficient from DWI, choline from MR spectroscopy, standard uptake values, metabolic tumor volume, and total lesion glycolysis of the tumors. Among all imaging parameters, Peak was found to be an independent predictor for overall survival in these patients. Thus, the imaging biomarkers from PET/MRI reflect different tumor characteristics and may predict survival outcome in these patients.

Liver disease is the third leading cause of death in Cystic Fibrosis (CF). Unfortunately, conventional liver function tests cannot sensitively detect it.¹⁻³ Liver stiffness measurements via MRI and ultrasound have shown promise but are unfortunately impacted by other factors (e.g., hepatic fat) potentially resulting in over-estimation of fibrosis.^{4,5} We recently validated a T1-MRI assessment of biliary dilatation and fibrosis in a rat model of congenital hepatic fibrosis (Figs. 1-3).⁶ In this clinical study, we show that T1-MRI can be used to sensitively detect increased percent bile duct volumes in CF patients in comparison to control subjects with normal liver function.

Reliable determination of bile acids from human gallbladder by 1H MRS - protocol optimization and estimation of reproducibility

Gaelle Diserens¹, Roland Kreis¹, Dino Kroell², Philipp Nett², Guido Stirnimann², Peter Vermathen¹, and Reiner Wiest²

¹Depts. Radiology and Clinical Research, University Bern, Bern, Switzerland, ²Dept. Visceral Surgery and Medicine, University Inselspital, Bern, Switzerland

Bile exerts multiple functions in the liver and gut with a crucial role for triglyceride-, sterol- and carbohydrate-metabolism and is a key player in disease processes. The study purpose was to develop a reliable MRS protocol and to assess variability of bile acid determination in human gallbladder. Our study demonstrated higher stability and reliability of gallbladder spectra with subjects measured in prone position compared to back position. Relatively small coefficients of variation were obtained in a reproducibility study particularly within subjects, suggesting clinical applicability of the method, especially for longitudinal studies.

Computer 106

Gadoxetate-disodium-enhanced T1-weighted R2* Mapping Improves Visualization of Biliary Anatomy in Liver Donor Candidates

Soudabeh Fazeli Dehkordy¹, Saya Igarashi¹, Carolina P Lamas Constantino^{1,2}, Jonathan Hooker¹, Cheng William Hong¹, Adrija Mamidipalli¹, Alan Hemming³, and Claude B Sirlin¹

¹Liver Imaging Group, Department of Radiology, University of California San Diego, San Diego, CA, United States, ²Dimagem Diagnóstico por Imagem, Rio de Janeiro, Brazil, ³Department of Surgery, University of California San Diego, San Diego, CA, United States

Gadoxetate-disodium (Gd-EOB-DTPA)-enhanced 3D T1-weighted (T1W) MR cholangiography (MRC) is recognized as an efficient method for evaluation of biliary anatomy, which is critical in the preoperative evaluation of living liver donors. We hypothesize that bile duct visualization could be improved by acquiring Gd-EOB-DTPA-enhanced T1W multi-echo (ME) gradient-echo (GRE) images and generating parametric R2* map cholangiograms. In 10 liver donor candidates, we retrospectively compared biliary duct visualization on T1W-R2* maps vs. 3D T1W cholangiograms obtained 20 minutes after IV administration of gadoxetate disodium. T1W-R2* maps provided comparable visualization of the first-order bile duct branches and better visualization of the second-order branches ($p < 0.05$).

Computer 107

Evaluation of T1 Parametric Mapping using Inversion Recovery Fast Spoiled Gradient Echo: Application for Pre- and Post-Contrast Liver MRI
Puneet Sharma¹, Xiaodong Zhong^{1,2}, Marcel Dominik Nickel³, Hiroumi Kitajima¹, and Pardeep Mittal¹

¹Department of Radiology and Imaging Sciences, Emory University, Atlanta, GA, United States, ²MR R&D Collaborations, Siemens Healthcare, Atlanta, GA, United States, ³MR Application Predevelopment, Siemens Healthcare, Erlangen, Germany

This investigation evaluates the performance and accuracy of a fast inversion recovery Look-Locker method for in vivo liver T1 mapping. Several parameters were assessed using T1 phantoms to describe accuracy trends and prevalence for artifacts. The method was also applied in vivo to demonstrate feasibility of fast T1 mapping of liver parenchyma and blood pool. The results offer insight into optimal imaging parameters, and showed good agreement with known T1 values at 1.5T.

3554

Computer 108

Black Blood T2-weighted Turbo Spin-Echo Imaging of the Liver with DANTE Preparation Module

Huimin Lin¹, Weibo Chen², Li Jiang², Lyu Li², Ruokun Li¹, and Fuhua Yan¹

¹Department of Radiology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, People's Republic of China, ²Philips Healthcare, Shanghai, People's Republic of China, ³Philips Healthcare (Suzhou), Suzhou, People's Republic of China

The purpose is to implement high resolution black blood T2-weighted TSE liver imaging in order to facilitate focal liver lesion detection and characterization. DANTE black blood preparation module, T2 weighted Multivane XD multi-slice acquisition and respiratory trigger were combined together. 8 healthy volunteers underwent MRI scanning on 3T Ingenia MR System. The black blood T2-weighted sequence showed high image quality and no artifacts. Hepatic veins, portal vein and their main branches were all suppressed successfully. No significant difference was shown in the SNR between black blood and routine T2-weighted images. In conclusion, the black blood T2-weighted imaging could provide robust and good imaging quality.

Computer 109

Splenic MR Elastography in Prediction of Hepatic Fibrosis Stage

Chen-Te Chou^{1,2} and Ran-Chou Chen^{3,4}

¹Radiology, Chang-Hua Christian Hospital, Chang-Hua, Taiwan, ²Biomedical Imaging and Radiological Sciences, National Yang-Ming University, Taipei, Taiwan, ³Health Promotion Administration, Ministry of Health and Welfare, ⁴Biomedical Imaging and Radiological Sciences, National Yang-Ming University, Taipei

The purpose of our study was to investigate the relationship between splenic MR elastography (MRE) and liver fibrosis stages. 109 patients underwent histological examination and abdominal MR examination within 3-months interval were enrolled in our study. MRE was performed with passive driver on right and left chest wall separately. The mean stiffness value of liver and spleen was determined and showed good correlation between hepatic/splenic stiffness and liver fibrosis stage. Our results demonstrated that spleen stiffness measured by MRE was significant correlated with liver fibrosis stage. Combination of the spleen/liver stiffness provide higher diagnostic value than liver stiffness alone.

Hepatocyte Fraction: Correlation with non-invasive liver functional biomarkers

Yoshifumi Noda¹, Satoshi Goshima¹, Tomoyuki Okuaki², Kimihiro Kajita¹, Hiroshi Kawada¹, Nobuyuki Kawai¹, Hiromi Koyasu¹, and Masayuki Matsuo¹

¹Department of Radiology, Gifu University, Gifu, Japan, ²Philips Healthcare, Tokyo, Japan

The hepatocyte fraction (HeF) is based on simple pharmacokinetics and can quantitatively estimate the fraction of hepatocyte. In our study, the HeF, quantitative liver-to-spleen contrast ratio (Q-LSC), and delta T1 value were compared and correlated with Child-Pugh and MELD score. The HeF demonstrated the highest correlations with Child-Pugh score ($r = -0.58$, $P < 0.0001$) and MELD score ($r = -0.57$, $P < 0.0001$). The HeF could be a useful biomarker for the evaluation of liver function, compared to conventional imaging based quantitative methods.

3557

Computer 111

Cardiac-induced liver deformation as a measure of liver stiffness: normal volunteer reproducibility and post-prandial stress studiesManil Chouhan¹, Alex Menys¹, Alan Bainbridge², David Atkinson¹, Shonit Punwani¹, Rajeshwar Mookerjee³, and Stuart Taylor¹¹UCL Centre for Medical Imaging, University College London, London, United Kingdom, ²Department of Medical Physicist, University College London Hospitals NHS Trust, London, United Kingdom, ³UCL Institute for Liver and Digestive Health, University College London, London, United Kingdom

Liver stiffness measured with elastography has useful clinical applications but requires the use of expensive, specialist equipment. In this study, we acquire dynamic 'cine' data of the liver to capture cardiac-induced liver motion during cardiac cine MRI. We quantify these data by applying a registration algorithm and use the deformation fields as a surrogate for liver stiffness. We demonstrate feasibility and good seven-day reproducibility and evaluate the effects of physiological haemodynamic changes using a liquid meal challenge. This technique would be widely applicable to hospital MRI scanners without elastography equipment.

3558

Computer 112

Investigation of liver cirrhosis using 31P-MRS at 7TLucian A. B. Purvis¹, William T. Clarke¹, Ladislav Valkovic¹, Christina Levick¹, Michael Pavlides², Eleanor Barnes², Jeremy F. Cobbold², Stefan Neubauer¹, Matthew D. Robson¹, and Christopher T. Rodgers¹¹OCMR, Department of Cardiovascular Medicine, University of Oxford, Oxford, United Kingdom, ²Translational Gastroenterology Unit, University of Oxford, Oxford, United Kingdom

Phosphorus (³¹P) metabolites have potential value as markers in liver disease. The increase in field strength from 3 to 7T allows more accurate quantitation of the liver ³¹P-MRS spectrum. Ten volunteers and eleven patients with liver cirrhosis were scanned using a 16-channel array and a 3D UTE-CSI sequence. Metabolite concentrations were calculated using an endogenous 2.5mM ATP reference. Significant reductions in inorganic phosphate and phosphoenolpyruvate/phosphatidylcholine concentrations were seen, as well as an increase in glycerophosphoethanolamine (P<0.05). The splitting of PDE into its constituent peaks allows more insight into changes in metabolism.

3559

Computer 113

Assessment of Liver Function of HBV-induced Cirrhosis using T1 Mapping on Gd-EOB-DTPA-Enhanced MRIXueqin Zhang¹, Jian Lu¹, Tao Zhang¹, Jifeng Jiang¹, Ding Ding¹, Sheng Du¹, and Weibo Chen²¹Nantong Third People's Hospital, Nantong University, Nantong, People's Republic of China, ²Philips Healthcare, Shanghai, People's Republic of China

The purpose of this study was to investigate the ability of T1 mapping on Gd-EOB-DTPA-enhanced MRI for the assessment of liver function of HBV-induced cirrhosis. We used Look-Locker sequences to acquire T1 mapping images pre and post-contrast at 5, 10, 15 and 20 minutes after Gd-EOB-DTPA administration, T1 relaxation times of the liver parenchyma were measured, reduction rates of T1 relaxation times between pre- and post-contrast enhancement were calculated, our study showed that Gd-EOB-DTPA-enhanced T1 mapping MRI is useful for the evaluation of Liver function of HBV-induced cirrhosis.

3560

Computer 114

Assessment of Hepatic Iron Content by an Automatic Vessel Exclusion Technique in Patients with Iron OverloadAaryani Tipirneni-Sajja¹, Ruitian Song¹, M. Beth McCarville¹, Ralf B. Loeffler¹, Jane S. Hankins², and Claudia M. Hillenbrand¹¹Diagnostic Imaging, St. Jude Children's Research Hospital, Memphis, TN, United States, ²Hematology, St. Jude Children's Research Hospital, Memphis, TN, United States

Extraction of liver parenchyma is an important step in the evaluation of R2*-based hepatic iron content. Traditionally this is performed by radiologists via thresholding, an iterative, time consuming process susceptible to interrater variability. Here, a new method based on Frangi vesselness filtering is presented that automatically removes hepatic vessels from liver tissue, thereby reducing potential bias and improving workflow. The method was evaluated in digital liver phantoms and 42 iron overloaded patients. Excellent agreement between manual and automated liver parenchyma segmentation was found which demonstrates accuracy and robustness of the proposed method.

3561

Computer 115

Steatohepatic Hepatocellular Carcinoma: Distinctive MR Imaging Features with Pathologic and OPTN CorrelationKelly Tung¹, Alvin Silva¹, Marcela Salomao², Christine Menias¹, Christine Zwart¹, Sukhdeep Singh¹, and Amy Hara¹¹Radiology, Mayo Clinic Arizona, Phoenix, AZ, United States, ²Pathology, Mayo Clinic Arizona, Phoenix, AZ, United States

Hepatocellular carcinoma (HCC) has specific imaging criteria such as arterial hyperenhancement, contrast washout, and pseudocapsule that allow it to be diagnosed with confidence and relative accuracy. However, a novel HCC variant, steatohepatic hepatocellular carcinoma (SH-HCC), has been described which tends to not exhibit the classic HCC imaging features. In this study, we explored alternative secondary MR features of HCC such as T1 and T2 signal intensity, intralesional fat, and restricted diffusion which may be more applicable in diagnosing steatohepatic hepatocellular carcinoma.

3562

Computer 116

Retrospective reconstruction of hepatic arterial phases in gadoxetic acid-enhanced liver MR using continuous golden-angle radial sequenceYoon-Chul Kim¹, Eunju Kim², Gabrielle Beck³, Hans Peeters³, and Young Kon Kim⁴¹Clinical Research Institute, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, ²Philips Healthcare, Seoul, Korea, Republic of, ³Philips Healthcare, Best, Netherlands, ⁴Radiology, Samsung Medical Center, Seoul, Korea, Republic of

We apply a 3D continuous golden-angle radial sparse parallel (GRASP) sequence to gadoxetic acid-enhanced imaging of the liver at 3 T. Arterial phase imaging may need high spatial and temporal resolution as well as correct timing of capturing arterial enhancement to obtain hemodynamic information of the tumor. Continuous golden-angle radial sampling provides a flexible retrospective selection of temporal window. We develop a technique that identifies the arterial peak from high temporal resolution data and reconstructs arterial phases with different temporal windows. The characteristics of hepatic arterial images after retrospective temporal resolution selection are demonstrated.

- 3563 Computer 117 [Qualitative and Quantitative Comparison of 2D Gradient Recalled Echo and Rapid 2D Gradient Recalled Echo Magnetic Resonance Elastography](#)

Ely R Felker¹, Steven S Raman¹, Bradley D Bolster², Holden Wu¹, Kyung Sung¹, Ning Jin², Brenda J Brown¹, and David S Lu¹

¹UCLA, Los Angeles, CA, United States, ²Siemens Healthcare, United States

Conventional GRE-based MR elastography requires a breath hold of approximately 18 seconds per slice, which is difficult for some patients. We compared a rapid GRE-based sequence (9 second breath hold) to conventional GRE in terms of quantitative liver stiffness (LS) measurement and image quality score (IQS), based on wave propagation and confidence mask coverage, determined by two independent radiologists. The two sequences were equivalent in terms of LS measurement, but the rapid GRE sequence had significantly higher IQS for both readers. Rapid GRE-based MR elastography may be an improved alternative to GRE in patients with limited breath hold capacity.

- 3564 Computer 118 [Evaluation of Portal Vein System Hemodynamics with Magnetic Resonance Angiographic Inflow-Sensitive Inversion Recovery](#)

Di Zhu¹, Xianlun Zou¹, Hao Tang¹, Xiao Chen¹, Xiaoyan Meng¹, Zhen Li¹, and Daoyu Hu¹

¹Department of Radiology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, People's Republic of China

To evaluate the ability of magnetic resonance angiographic inflow-sensitive inversion recovery (IFIR-MRA) to assess hemodynamics of portal vein system in patients with portal hypertension, we compared visualized portal vein branching grade scores at different blood suppression inversion time (BSP TI) settings and signal intensity contrast ratio of the vessels and the liver parenchyma with color Doppler ultrasonography (CDUS) measured hemodynamics. Statistically significantly correlation demonstrated that IFIR-MRA of portal vein system has the potential to suggest hemodynamic changes, especially for RPV.

- 3565 Computer 119 [Validation of Feasibility of Magnetic Resonance Imaging for the Measurement of Depth of Tumor Invasion in Distal Bile Duct Cancer](#)

Na Yeon Han¹, Min Ju Kim¹, Beom Jin Park¹, Deuk Jae Sung¹, Ki Choon Sim¹, Ki Choon Sim¹, and Sung Bum Cho¹

¹Korea University Anam Hospital, Seoul, Korea, Republic of

We performed the study to develop and validate a method for measuring the depth of tumor invasion (DoI) on magnetic resonance imaging (MRI) and to investigate the diagnostic performance of the measured DoI for stratifying T classification in patients with distal bile duct cancer. Our result showed that this newly developed method reliably measured DoI on T2-weighted MR images, and can be used for the preoperative T classification of distal bile duct cancer patients.

- 3566 Computer 120 [Pancreatic exocrine function estimated by cine dynamic MRCP with a spatially selective IR pulse: Correlation with T1 mapping of the pancreatic parenchyma](#)

Katsuyoshi Ito¹, Akira Yamamoto¹, Kazuya Yasokawa¹, Minoru Hayashida¹, Daigo Tanimoto¹, Akihiko Kanki¹, Tomohiro Sato¹, Hidemitsu Sotozono¹, Takeshi Fukunaga¹, Koji Yoshida¹, Kazunori Moriya¹, and Tomoyuki Okuaki²

¹Radiology, Kawasaki Medical School, Kurashiki, Japan, ²Philips Healthcare AsiaPacific, Japan

This study assessed the correlation between pancreatic exocrine function estimated by cine dynamic MRCP with a spatially selective IR pulse and T1 mapping of the pancreatic parenchyma on 3T MR imaging. There was a statistically significant correlation between the secretion grade of the pancreatic juice in cine-dynamic MRCP and T1 relaxation time of the pancreatic parenchyma. Therefore, T1 mapping of the pancreatic parenchyma will be used as collaborative, noninvasive technique of cine-dynamic MRCP with a spatially selective IR pulse for the estimation of pancreatic exocrine function.

Exhibition Hall

Monday 16:15 - 17:15

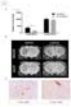

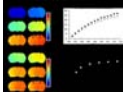

- 3567 Computer 1 [Detection of Acetaminophen-Induced Liver Damage using Contrast-Enhanced Dynamic MRI and T1 Maps](#)

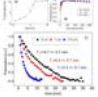

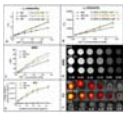

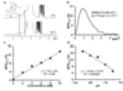

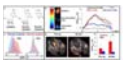

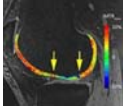

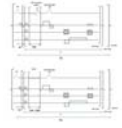

Christiane L Mallett¹, Matthew Latourette¹, Jeremy Hix¹, Alexander Wolf¹, and Erik M Shapiro¹

¹Radiology, Michigan State University, East Lansing, MI, United States

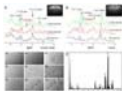

We are developing an MRI method to measure acetaminophen toxicity in the liver. We obtained dynamic T1 weighted images of the liver and T1 maps using the clinically approved contrast agent gadoxetate disodium (Eovist). After acetaminophen overdose, the uptake of contrast was decreased in the liver and increased in the kidney. T1 and variation in T1 were higher after acetaminophen. T1 was correlated with ALT, a serum measure of liver damage. This is a promising method for quantifying drug induced liver damage in vivo.

-
- 3568 **Computer 2** **A Transgenic Method to Enhance Intracellular Retention of Iron Oxide Nanoparticles and Prolong MRI Tracking**
 Xiaoyong Zhang¹, Ximei Qian², Sha Wang¹, and Xiaoping Hu¹

¹Bourns college of engineering, University of California, Riverside, CA, United States, ²Department of Biomedical Engineering, Emory University
- Iron oxide nanoparticles (IONPs) are widely used as labels for noninvasive cell tracking using magnetic resonance imaging (MRI). However, IONP induced contrast dilutes rapidly over time due to cell growth and division, limiting its applications in long-term cellular visualization. In the present work, unlike techniques focusing on modification of IONPs, we established a novel transgenic approach to increase IONP retention, significantly prolonging the tracking time of IONP labeled cells. In addition, this approach could be generalized to other cell types and magnetic nanoparticles, making it attractive for long-term cell tracking or tumor progression monitoring.
-
- 3569 **Computer 3** **Comparison of USPIO and MPIO for molecular MRI across different field strengths**
 Niloufar Zarghami¹, Alexandr Khrapichev¹, Francisco Perez-Balderas¹, Manuel Sarmiento-Soto¹, and Nicola Ruth Sibson¹

¹Department of Oncology, University of Oxford, Oxford, United Kingdom
- We have previously reported molecular MRI studies using Microparticles of Iron Oxide (MPIO) coupled to anti-VCAM-1 antibodies. However, Ultrasmall Superparamagnetic Iron Oxide (USPIO) are more commonly used in MRI applications. Although MPIO provide greater targeting valency and contrast per particle, their advantages over USPIO for molecular MRI has not been demonstrated empirically. Here, we compared the sensitivity and specificity of VCAM-MPIO and VCAM-USPIO for molecular MRI; VCAM-MPIO, but not VCAM-USPIO, yielded marked and selective contrast in areas of cerebral inflammation. These results confirm the theoretical assumption that MPIO present a more viable platform for molecular MRI than USPIO.
-
- 3570 **Computer 4** **3 nm iron oxide nanoparticles as spin-lattice relaxation time enhancing contrast agents.**
 Joong Hee Kim¹, Taeghwan Hyeon², and David L. Brody³

¹Neurology, Washington University School of Medicine in St. Louis, St. Louis, MO, United States, ²Seoul National University, ³Washington University School of Medicine in St. Louis
- Relaxation based MR images have superior spatial resolution compared to other MRI approaches. In addition, structural MRI requires short scan time and yet has high signal to noise ratio. However, the greatest limitation of structural MRI is poor specificity and sensitivity to pathology. Thus a well characterized MR molecular contrast agent would be a major advance. Here we present 3 nm iron oxide nanoparticles (IONP) as a T1 contrast agent. The 3 nm IONP showed strong T1 effects up to 13.5 ms echo time. A fully functionalized 3 nm IONP would be an appropriate component for molecular contrast agents.
-
- 3571 **Computer 5** **Engineered Protein-Iron Oxide Hybrid Biomaterial for MRI-monitoring of Drug Delivery**

- 3572 **Computer 6** **Direct hyperpolarization of micro- and nanodiamonds for bioimaging applications – considerations on particle size, functionalization and polarization loss**
 Grzegorz Kwiatkowski¹, Jonas Steinhauser¹, Patrick Wespi¹, Matthias Ernst², and Sebastian Kozerke¹

¹Institute for Biomedical Engineering, ETH Zurich, Zurich, Switzerland, ²Physical Chemistry, ETH Zurich, Zurich, Switzerland
- Due to the inherently long relaxation time of ¹³C spins in diamonds, the nuclear polarization enhancement obtained with dynamic nuclear polarization can be preserved for a time on the order of ~1h, opening up a window for a new class of long-lived contrast agents. Up to now, no imaging with hyperpolarized micro and nanodiamonds has been reported. The present communication presents the feasibility of applying directly hyperpolarized diamonds in MR imaging including considerations for potential in-vivo applications.
-
- 3573 **Computer 7** **A novel multimodal mannan-based polymer system suitable for tumor and metastasis diagnosis**
 Andrea Galisova¹, Marketa Jiratova¹, Maria Rabyk², Martin Hruby², Milan Hajek¹, and Daniel Jirak¹

¹MR Unit, Institute for Clinical and Experimental Medicine, Prague, Czech Republic, ²Institute of Macromolecular Chemistry, Prague, Czech Republic
- Presented mannan-based polymers have promising properties for tumor and metastasis imaging due to their biocompatibility, nanosize and specificity for the immune cells. In this study, two mannan-based polymers were tested by multimodal imaging (MRI and fluorescence). The polymers showed superior imaging properties compared to a commercially available contrast agent. The polymer modified with oxazoline expressed slower elimination rate from the body. Both probes were visualized by MR and optical imaging modality at the injection sites and in the lymph nodes of the experimental mice suggesting their promising properties for cancer diagnosis.

- 3574 **Computer 8** **CEST MRI using sugar alcohol, maltitol, to detect cancer: Study on rat glioma model**
 Puneet Bagga¹, Mohammad Haris², Kevin D'Aquilla¹, Francesco Marincola², Hari Hariharan¹, Ravinder Reddy¹, and Puneet Bagga³

¹Department of Radiology, University of Pennsylvania, Philadelphia, PA, United States, ²Research Branch, Sidra Medical and Research Center, Doha, Qatar, ³Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States
- We show the use of a sugar alcohol sweetener, maltitol, in cancer MRI studies by exploiting its chemical exchange saturation transfer (malCEST) property. The tumor specific accumulation of maltitol in a rat glioma model provides localized, temporal changes in the CEST contrast, which corroborated the gadolinium-enhanced MRI. These findings illustrate the potential application of maltitol in the diagnosis and monitoring of the therapeutic response of cancers, including gliomas in preclinical studies.

¹Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²FM Kirby Research Center, The Kennedy Krieger Institute, Baltimore, MD, United States
- Magnetic Resonance Imaging (MRI) is rarely used for molecular binding studies and never without synthetic metallic labels. We designed an MRI approach that can selectively detect substrate-target interaction by exploiting the narrow resonance of protons in free substrate for selective radio-frequency (RF) labeling and, subsequently, the process of immobilisation upon binding to a solid-like target for fast dipolar transfer of this label over the protons in its backbone. This cascade of events is ultimately detected via the water MRI signal with enhanced sensitivity. We demonstrate the principle for caffeine binding *in vitro* and *in vivo*.
-
- 3576 **Computer 10** **In vivo CEST MRI of specific activated T-cells population using the natural nucleoside cytidine**
 Hyla Allouche-Amon¹ and Amnon Bar-Shir¹

¹Organic Chemistry, Weizmann Institute of Science, Rehovot, Israel
- Non-invasive imaging of inflammation is crucial for understanding both inflammatory processes and immunotherapy. We propose a non-invasive and non-radioactive approach for longitudinal imaging of activated immune cells. We show that the use of the natural nucleoside cytidine as CEST imaging probe enable the monitoring of specific activated T-cells population with MRI. By using fluorescent analog of cytidine it is shown that CD8 T-cells are *in situ* labeled, underlying the specificity of nucleosides as potential probes for monitoring activated immune cells. We conclude that by using cytidine as a MRI-based probe one could monitor specific activated T-cells population during inflammation.
-

- To the best of our knowledge, this is the first study that employs gagCEST for the longitudinal evaluation of untreated articular cartilage defects. We demonstrate that gagCEST at 7T has the potential of discriminating between cartilage defects, weight bearing and non-weight bearing femoral cartilage and therefore might serve as a biomarker for the evaluation of novel cartilage therapies. Furthermore, our study implies that proper fixation of the examined knee may help to increase the reliability of gagCEST experiments.
-
- 3578 **Computer 12** **Lipo2-DG-CEST: a new theranostic agent for simultaneous tumour imaging and chemotherapy**
 Eleni Demetriou¹, Harriet Story², Robin Bofinger², Karin Shmueli³, Helen Hailes², Alethea Tabor², and Xavier Golay¹

¹Brain Repair and Rehabilitation, Institute of Neurology, London, United Kingdom, ²Department of Chemistry, University College of London, London, United Kingdom, ³Department of Medical Physics & Bioengineering, University College of London, London, United Kingdom
- 2-DG has been shown to inhibit tumor growth *in vivo*; however, it cannot be used as a therapeutic agent in humans due to its toxicity. Here we show the potential for 2-DG-loaded liposomes to provide detectable Chemical Exchange Saturation Transfer (CEST) contrast, and thereby achieve simultaneous tumour imaging and chemotherapy by targeting areas of greater tumour metabolism. The CEST signal arising from 2-DG was compared to liposome-encapsulated 2-DG and to natural D-glucose, respectively. The results demonstrated an increase in signal for 2-DG loaded liposomes when compared to both free 2-DG and glucose possibly due to a decrease in the global exchange rate.
-
- 3579 **Computer 13** **PRO-QUEST: A fast method for exchange rate quantification based on PROgressive saturation for Quantifying Exchange using Saturation Times in Chemical Exchange Saturation Transfer (CEST)**
 Eleni Demetriou¹, Mohamed Tachrount¹, Karin Shmueli², and Xavier Golay¹

¹Brain Repair and Rehabilitation, Institute of Neurology, London, United Kingdom, ²Department of Medical Physics & Bioengineering, University College of London, London, United Kingdom

In this work we propose a novel pulse sequence for measuring chemical exchange rates through a progressive saturation recovery process PRO-QUEST (PROgressive saturation for Quantifying Exchange using Saturation Times). The water magnetization is sampled under non-steady state conditions and saturation is interleaved with the acquisition of images obtained in a single scan. Unlike previous approaches, it provides maps of T_1 and B_1 , needed for exchange-rate calculations, from the same dataset. The proposed pulse sequence has been successfully applied to obtain exchange rate maps in phantoms and healthy rat brains.

Jing Wang¹, Jianxun Qu², Tianyong Xu², and Zhenwei Yao¹

¹Radiology, Huashan Hospital of Fudan University, Shanghai, People's Republic of China, ²GE Healthcare, Shanghai, People's Republic of China

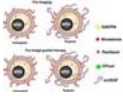

The β-alanine loaded hollow mesoporous silica nanospheres (AMSNs) with a characteristic MRS spectrum are successfully synthesized and used for contrast enhanced magnetic resonance spectroscopy (MRS) imaging of brain glioma. Material characterizations, in vitro and in vivo cytotoxicity studies and contrast enhanced MRS imaging of both subcutaneously transplanted glioma and in situ glioma are conducted with the synthesized AMSNs.

- 3581 Computer 15 [MR Imaging of Nanoparticle Uptake and 3D Intra-tumoral Distribution in Orthotopic Xenograft Mouse Models of Neuroblastoma](#)
Ketan B Ghaghada¹, Saakshi Bhayana¹, Igor Stupin¹, Flavia Leao Barbosa¹, Chandresh Patel¹, Zbigniew Starosolski¹, and Ananth Annappagada¹

¹Pediatric Radiology, Texas Children's Hospital, Houston, TX, United States

Heterogeneity in tumor vasculature gives rise to variability in vascular permeability, one of the consequences being non-uniform intra-tumoral uptake and distribution of nanoparticle-based chemotherapeutics. An imaging agent that can assess tumor vascular heterogeneity and monitor uptake and distribution of nanoparticles could be useful for guiding and monitoring nanoparticle-based chemotherapy. In this work, we demonstrate, in orthotopic mouse models of solid tumors, that a high T1 relaxivity liposomal-gadolinium contrast agent (liposomal-Gd) enables MR imaging of nanoparticle uptake and 3D intra-tumoral distribution at clinically-relevant MR field strength.

- 3582 Computer 16 [A high-relaxivity extracellular matrix fibronectin targeting gadolinium metallofullerene for cancer detection and differential diagnosis in molecular MRI](#)
Zheng Han¹ and Zheng-Rong Lu¹

¹Case Western Reserve University, Cleveland, OH, United States

Accurate cancer detection and characterization with MRI is hampered by the lack of safe and effective targeted MRI contrast agents. In this work, we have designed and synthesized a high-relaxivity targeted contrast agent by conjugating ZD2 peptide to hydroxylated Gd₃N@C80. ZD2-Gd₃N@C80 has a high T₁ relaxivity of 76.4 mM⁻¹s⁻¹ per Gd at 1.5 Tesla and a small diameter of 1 nm on average. At a low dose of 5 μmol Gd/kg, ZD2-Gd₃N@C80 is able to produce prominent contrast enhancement in the highly metastatic MDA-MB-231 triple-negative breast cancer model, but not in the estrogen-dependent MCF-7 tumors.

- 3583 Computer 17 [MR/optical image-guided liposomal drug delivery system for triple negative breast cancer](#)
Sudath Hapuarachchige¹, Wenlian Zhu¹, Yoshinori Kato^{1,2}, Marina V. Backer³, Susanta Sarkar⁴, Joseph M Backer^{1,3}, and Dmitri Artemov^{1,5}

¹Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²Life Science Tokyo Advanced Research Center (L-StaR), Hoshi University School of Pharmacy and Pharmaceutical Science, Tokyo, Japan, ³SibTech, Inc., Brookfield, CT, ⁴CadenzaMed LLC, Wayne, PA, ⁵Department of Oncology, The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD, United States

Noninvasive image-guided drug delivery is important in cancer drug development, and allows visualizing the delivery and predicting the outcome. In this study, the delivery and therapeutic effects of liposomes targeted to tumor vasculature was researched. Intravital microscopy and MRI were used for tracking the drug delivery and therapeutic effects were monitored in MDA-MB-231 mouse tumor model. Our experimental results suggest that targeting liposomes to VEGF receptors (VEGFRs) expressed on tumor endothelium, may inhibit EPR-mediated extravasation and accumulation of VEGFR-targeted liposomes.

- 3584 Computer 18 [Use of Gadofosveset-enhanced Lung MRI to Assess Ongoing Lung Injury in Fibrotic Interstitial Lung Disease.](#)
Sydney B Montes¹, Rohan Rao¹, Lloyd Liang¹, Subba Digumarthy², Amita Sharma², Peter Caravan², Andrew Tager¹, and Ravi Seethamraju³

¹Medicine, Pulmonary and Critical Care, Massachusetts General Hospital, Boston, MA, United States, ²Radiology, Massachusetts General Hospital, Boston, MA, United States, ³Siemens Healthcare, Boston, MA

Vascular leak is a cardinal response to injury, and prior assessments of alveolar-capillary permeability suggest that vascular leak is present in the lungs of patients, and that its extent is associated with progression and mortality. We hypothesized that the degree of vascular leak present reflects the extent of ongoing lung injury, and that measuring lung vascular permeability consequently could provide a much-needed metric for assessing ILD disease activity and predicting disease progression. Using magnetic resonance imaging with the albumin-binding contrast agent gadofosveset, we were able to detect increased vascular permeability in the lung of patients with fibrotic ILD.

- 3585 Computer 19 [MRI assessment of spatial distribution of hypoxia in pre-clinical xenograft models of non-small cell lung cancer via GdDO3NI: A Novel Hypoxia-Binding T1 Contrast Agent](#)

Aza-BODIPY Derivative for Gadolinium-enhanced MR and Near-infrared Fluorescence Dual Imaging

Hyunseung Lee¹, Eun-jung Kim¹, Hyun Min Kim¹, and Kwan Soo Hong^{1,2}

¹Bio-imaging Research Team, Korea Basic Science Institute, Cheongju, Korea, Republic of, ²Graduate School of Analytical Science and Technology, Chungnam National University

A novel dual imaging probe for in vivo magnetic resonance imaging (MRI) and optical imaging was developed by combining gadolinium (Gd)-chelating MR probe and a near-infrared (NIR) fluorophore, aza-BODIPY (AB; BODIPY = borondipyrromethene). This aza-BODIPY-based bimodal contrast agent (AB-BCA) showed a significant fluorescence emission around the NIR range and an enhanced longitudinal relaxivity in MR modality. The probe was easily delivered to phagocytic cells of the innate immune system, together with macrophages and dendritic cells (DCs), and presented high-performance fluorescence and MR imaging without obvious cytotoxicity.

A novel theranostic thermo-responsive 19F probe for tumor imaging

Daniel Jirak¹, Andrea Galisova¹, Ondrej Sedlacek², Martin Hruby², and Milan Hajek¹

¹IKEM, Prague, Czech Republic, ²Institute of Macromolecular Chemistry of the Academy of Sciences, Prague, Czech Republic

Novel ¹⁹F MR probe with the ability of creation of a depot in the living system is presented. This agent is pH- and thermo-responsive with the phase transition point from liquid into the solid state at the temperature above 20 °C. The MR properties were assessed by relaxometry and ¹⁹F spectroscopy/imaging. *In vivo* application confirmed efficiency of depot visualization; strong ¹⁹F MR signal was detected in all animals. No adverse effects of the probe to the animals were observed. Sufficient MR sensitivity of the probe and its slow degradation in animals suggest potential for a theranostic use.

Characterization of Inflammation Induced by Exposure to Primary Blast Waves in Rats using 19F MRI

Lesley M Foley¹, James C DeMar², Andrew B Batuure², William B Rittase², John G Rosenberger², Donna M Wilder², Patrick M Kochanek³, Joseph B Long², and T Kevin Hitchens^{1,4}

¹Animal Imaging Center, University of Pittsburgh, Pittsburgh, PA, United States, ²Center for Military Psychiatry and Neuroscience Research, Walter Reed Army Institute of Research, Silver Springs, MD, United States, ³Safar Center for Resuscitation Research, University of Pittsburgh, Pittsburgh, PA, United States, ⁴Department of Neurobiology, University of Pittsburgh, Pittsburgh, PA, United States

Our objective is to longitudinally monitor the nature and timing of immune cell guided inflammatory processes following multiple blasts in an animal model, in an effort to discern potential therapeutic windows. Blast, results in a heterogeneous whole-body inflammatory response that can be observed with a perfluorocarbon contrast agent and ¹⁹F MRI. A second closely timed blast increased the amount of fluorine signal in injured rats, which most likely represents increased macrophage accumulation. Despite having potent anti-inflammatory properties, we did not observe that a diet rich in omega-3 fatty acids has a significant impact on the inflammatory response to blast injuries.

A novel application of quantitative sodium MRI for distinguishing lipedema from obesity

Rachelle Crescenzi¹, Adriana Marton², Paula MC Donahue^{3,4}, Helen B Mahany¹, Ping Wang¹, Joshua A Beckman⁵, Manus J Donahue^{1,6,7,8}, and Jens Titze²

¹Radiology and Radiological Sciences, Vanderbilt University Medical Center, Nashville, TN, United States, ²Pharmacology and Physiology, Vanderbilt University, Nashville, TN, United States, ³Physical Medicine and Rehabilitation, Vanderbilt University Medical Center, Nashville, TN, United States, ⁴Vanderbilt Dayani Center for Health and Wellness, Nashville, TN, United States, ⁵Cardiovascular Medicine, Vanderbilt University Medical Center, Nashville, TN, United States, ⁶Neurology, Vanderbilt University Medical Center, Nashville, TN, United States, ⁷Psychiatry, Vanderbilt University Medical Center, Nashville, TN, United States, ⁸Physics and Astronomy, Vanderbilt University, Nashville, TN, United States

Sodium MRI is a molecular imaging tool that may be sensitive to the impact of lymphatic impairment on tissue homeostasis, yet has not been evaluated in a clinical population with a lymphatic disorder. Lipedema is a lymphatic fat-disorder that is under-recognized due to a need for further advanced MR imaging to diagnosis and assess treatment efficacy of the condition. Here, we apply quantitative 3T sodium imaging for the first time in a lipedema cohort to quantify tissue sodium levels and found elevated sodium concentration in the skin and muscle of patients with lipedema compared to BMI- and age-matched controls.

The verification of the T2 distributed relaxation model (DRM) for a polydisperse nanoparticle system

Bashar Issa¹

¹Physics, UAE University, Al-Ain, United Arab Emirates

Theories describing T_2 enhancement due to the presence of superparamagnetic particles agree well with experimental and Monte Carlo simulation data under the condition that the particles are monodisperse both in size and magnetization. We present a T_2 distributed model that takes into account the particle size and magnetization distributions. The results shown confirm the ability of the distributed relaxation model to correctly predict T_2 values for a mixed MAR and SDR sample of MNP under a wide range of values of size, magnetization, volume fraction, etc. The new model will reduce the error in calculating T_2 values using the mean size and mean magnetization values when a distribution of MNP exists.

Leucine deprivation causes hypothalamic neuronal inhibition accompanied by systemic metabolic changes.

Anna Ulyanova¹, Jadegoud Yaligar¹, Anantharaj Rengaraj¹, Tian Xianfeng¹, Venkatesh Gopalan¹, Sanjay K Verma¹, Christiani Jeyakumar Henry², and S Sendhil Velan¹

¹Laboratory of Molecular Imaging, Singapore Bioimaging Consortium, A*STAR, Singapore, Singapore, ²Clinical Nutrition Research Centre, Singapore Institute for Clinical Sciences, A*STAR, Singapore, Singapore

The lack of dietary essential amino acid leucine influences energy metabolism via hypothalamic leptin signaling pathway. However, these neural circuits and its relationship with pathogenesis of obesity still remain unclear. In this work we investigated the hypothalamic neural pathway, abdominal fat and liver fat by multi-parametric imaging in leucine deficient diet fed mice. MEMRI results indicated that leu deficiency triggers neuronal inhibition in certain hypothalamic regions suggesting POMC neuronal pathway involvement in enhanced energy expenditure through leptin signaling pathway. Combined with systemic metabolic changes this may facilitate in understanding of amino acid sensing and metabolic regulatory network of energy homeostasis.

Detecting neuronal activity in rat model of dementia with Lewy bodies by using MEMRI

Meng-Syuan Lin¹, Ying-Jui Ho², and Jun-Cheng Weng^{1,3}

¹Department of Medical Imaging and Radiological Sciences, Chung Shan Medical University, Taichung, Taiwan, ²Department of Psychology, Chung Shan Medical University, Taichung, Taiwan, ³Department of Medical Imaging, Chung Shan Medical University Hospital, Taichung, Taiwan

Dementia with Lewy bodies (DLB) is thought to be the second commonest cause of neurodegenerative dementia in older people, accounting 15 to 25% cases at autopsy. However, to date there are no reliable methods of instrumental and laboratory diagnosis of this disease while its treatment is based on reducing the symptoms. The drug X has been shown to have neuroprotective effects in neurodegenerative diseases. Therefore, we aimed to clarify the medicinal effectiveness of drug X through manganese-enhanced magnetic resonance imaging (MEMRI). Our results indicated that drug X may have clinical potential in the treatment of DLB.

Computer 31

Precise longitudinal MRI tracking of systemically infused dual labelled mesenchymal stem cells and their regenerative potential in traumatic brain injury mice
Sushanta Kumar Mishra^{1,2}, Subash Khushu¹, and Gurudutta Gangenahalli²

¹NMR Research Centre, Institute of Nuclear Medicine and Allied Sciences, Delhi, India, Delhi, India, ²Division of Stem Cell and Gene Therapy Research, Institute of Nuclear Medicine and Allied Sciences, Delhi, India

Stem cells transplantation has emerged as a promising alternative therapeutic due to its potency at injury site. Thus, tracking of stem cells is very essential. Here, we have described a serial *in vivo* tracking of implanted stem cells through 7T MRI and its differentiation potential into neuronal precursors. T2*-weighted images and relaxation study demonstrated a significant signal loss and effective decrease in T2* relaxation time on day-3 at injury site. Expression of neuronal markers like GFAP, MAP2 and NeuN were observed in transplanted MSCs. The proposed procedure could be extrapolated for stem cell tracking and therapies in various neurodegenerative diseases.

¹Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, ²Cardiovascular Division, The British Heart Foundation Centre of Excellence, King's College London, London, United Kingdom, ³Heinrich Heine University Düsseldorf, Düsseldorf, Germany, ⁴Cardiovascular Division, James Black Centre, King's College London, London, United Kingdom

After a myocardial infarction (MI) the degree of inflammation and its timely resolution, together with the degradation and deposition of extracellular matrix proteins are key processes in post-MI healing. Monocyte chemoattractant protein-1 (MCP1) plays an important role in the recruitment of monocytes/macrophages and its absence has revealed a significant reduction of inflammatory cell recruitment and subsequent ECM protein production in the infarcted area. Here, we explored the merits of multinuclear ¹H/¹⁹F MRI for the simultaneous assessment of myocardial inflammation and remodelling in a murine model of MI. ¹⁹F containing nanoparticle that is avidly taken up by macrophages was used to investigate inflammatory cell recruitment into injured myocardium², and a small molecular weight gadolinium-based elastin-specific MR contrast agent was used to evaluate changes of elastin content post-MI³.

¹⁹F-based MRI cell tracking shows that the density of tumour associated macrophages in breast tumours corresponds to tumour aggressiveness and metastatic potential
Ashley V Makela^{1,2}, Jeffrey M Gaudet^{1,2}, and Paula J Foster^{1,2}

¹Medical Biophysics, Western University, London, ON, Canada, ²Robarts Research Institute, London, ON, Canada

Tumour associated macrophages (TAMs) have been associated with tumour aggressiveness, including tumour growth and metastatic potential. ¹⁹F-based MRI is used in this study to track these cells *in vivo*, revealing the ability to differentiate TAM content between 3 murine models of breast cancer. Highly aggressive tumours had significantly higher ¹⁹F signal when compared to the low and non aggressive variants. This information may be of use as a biomarker, to differentiate between tumours with high infiltration of TAMs, which have the propensity to metastasize and progress quicker, versus tumours with less TAMs, which may not advance as quickly.

Morgan Department of Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, MD, United States

Total choline in tumors is associated with increased aggressiveness. Since the distribution of total choline in tumors is usually heterogeneous, here we have examined the relationship between high and low total choline, obtained with 1H MRSI, with hypoxia and necrosis in a human breast cancer xenograft model engineered to express red fluorescence protein under hypoxic conditions. We found that the highest total choline regions were associated with hypoxia. We also observed that overall total choline in tumors inversely correlated with the necrotic fraction, suggesting that reduced total choline may reflect increased cell death in tumors.

3D CMRO₂ Mapping in Human Brain with Direct ¹⁷O-MRI: Comparison of Methods for Image Reconstruction and Partial Volume Correction

Dmitry Kurzhunov¹, Robert Borowiak^{1,2,3}, Marco Reiser¹, Axel Joachim Krafft¹, Ali Caglar Özen¹, and Michael Bock¹

¹Dept. of Radiology, Medical Physics, Medical Center – University of Freiburg, Freiburg, Germany, ²German Cancer Consortium (DKTK), Heidelberg, Germany, ³German Cancer Research Center (DKFZ), Heidelberg, Germany

This study presents a comparative analysis of different reconstruction techniques for quantification of 3D maps of the cerebral metabolic rate of oxygen consumption (CMRO₂) in human brain. CMRO₂ maps were calculated from a direct ¹⁷O-MRI experiment at 3T in which ¹⁷O gas was inhaled. Conventional Kaiser-Bessel reconstruction of ¹⁷O MR images was compared to two iterative reconstruction methods using total variation (TV) and anisotropic diffusion (AD) of coregistered proton data as constraints. AD-constraint reconstruction, which acts as a non-homogeneous edge-preserving smoothing filter, enabled CMRO₂ mapping at clinical field strengths by increasing the SNR, and reducing partial volume effects.

In order to understand complex mechanisms of the tumor biology, multimodal imaging approaches are useful. Here we present a workflow to characterize subcutaneous MAT-B-III tumors in rats on a clinical 3T PET/MR. Proton imaging was used for tumor localization and to characterize tumor cellularity by diffusion-weighted imaging. Glucose uptake and downstream glucose metabolism of pyruvate by lactate dehydrogenase (LDH) was addressed by [18F]FDG-PET and hyperpolarized [13C]pyruvate metabolic imaging. The [18F]FDG standard uptake values and the LDH activity were consistently and reproducibly higher compared to normal tissue.

Imaging branched-chain amino acid metabolism in glioma using hyperpolarized [1-13C] alpha-ketoisocaproate

Eul Hyun Suh¹, Weijun Ou^{1,2}, Ian Corbin¹, Dean Sherry^{1,3}, and Jae Mo Park¹

¹Advanced Imaging Research Center, University of Texas Southwestern Medical Center, Dallas, TX, United States, ²Organ Transplantation Center, Sun Yat-sen University, Guangzhou, People's Republic of China, ³Chemistry, University of Texas Dallas, Richardson, TX, United States

Upregulated branched-chain amino transaminase 1 (BCAT1) expression is a common metabolic feature of most primary cancers with wild-type isocitrate dehydrogenase (IDH), including glioblastoma. In this study, ¹³C-labeled α-ketoisocaproate (KIC) metabolism was investigated in a brain tumor-bearing rat to assess BCAT1 and branched-chain α-ketoacid dehydrogenase (BCKDH) activities in the tumor. Following an intravenous bolus injection of hyperpolarized [1-¹³C]KIC, both [1-¹³C]leucine and ¹³C-bicarbonate were observed in the brain. We observed less [1-¹³C]leucine but greater bicarbonate production in the tumor compared to normal, healthy brain tissue, suggesting downregulated chemical exchange of [1-¹³C]KIC with leucine catalyzed by BCAT1 and upregulated BCKDH activity, respectively.

Metabolic changes in the heart precede functional changes in a rat model of doxorubicin-induced cardiotoxicity

Kerstin N Timm¹, Jack J Miller¹, Dragana Savic¹, Vicky Ball¹, Lucia Giles¹, Cher-Rin Chong¹, Michael S Dodd¹, and Damian J Tyler¹

¹Physiology Anatomy and Genetics, University of Oxford, Oxford, United Kingdom

Chemotherapeutic agents such as doxorubicin can cause serious adverse effects on the heart, leading to decreased left ventricular function and heart failure. The biochemical mechanisms for this are not fully understood, however, increased oxidative stress in cardiomyocytes as well as bioenergetic changes to the heart have been suggested as primary triggers for the functional decline. Here we show that hyperpolarized ^{13}C magnetic resonance spectroscopy and CINE magnetic resonance imaging of the heart can detect metabolic as well as functional changes in a clinically relevant rat model of doxorubicin-induced cardiotoxicity, and that metabolic changes may precede functional abnormalities.

Deranged metabolism is now considered a key causal factor in heart failure and has therefore gained considerable scientific interest. The novel technique hyperpolarized MR has emerged as a leading methodological candidate to study these derangements. We employed a clinically relevant, large animal model of angiotensin-II-mediated acute hypertension to study cardiac metabolism in the setting of elevated afterload using hyperpolarized [1- ^{13}C]Pyruvate MR. The method was able to detect acute increases in both anaerobic and aerobic cardiac metabolism, which, in the future could mean a useful way of monitoring a possible treatment response to afterload reduction by using hyperpolarized MR.

Hyperpolarized [1- ^{13}C]Pyruvate MRI identifies metabolic differences pertaining to the fasted and fed state in porcine cardiac metabolism

Rasmus Stilling Tougaard^{1,2}, Esben Søvsø Szocska Hansen², Christoffer Laustsen², Thomas Stokholm Nørtinger², Emmeli Mikkelsen², Jakob Lindhardt², Marie Schroeder², Per Mose Nielsen², Lotte Bonde Bertelsen², Hans Erik Bøtker¹, Won Yong Kim^{1,2}, Henrik Wiggers¹, and Hans Stødkilde-Jørgensen²

¹Department of Cardiology - Research, Aarhus University Hospital, Aarhus N, Denmark, ²MR Research Centre, Aarhus University, Aarhus N, Denmark

Standardized large animal models for cardiac hyperpolarized MR metabolic studies are becoming increasingly important as translation into human trials progresses. We employed a porcine (n=17) model of fasting/feeding to study these two states and to examine normal feeding as a standardized model for increasing hyperpolarized [1- ^{13}C]Pyruvate signal in the heart. All metabolic ratios were higher in fed animals with no additional variance. This indicates the role of pyruvate uptake to be more important in pigs than in rodents, underlining the need for large animals in metabolic research, and also suggests feeding to be a feasible, standardized model for increasing signal.

The Pyruvate Dehydrogenase Complex (PDC) plays a critical role in the regulation of carbohydrate metabolism. Pyruvate Dehydrogenase Kinase (PDK) inhibits PDC via phosphorylation making it a novel therapeutic target for metabolic diseases. The present study aimed to evaluate whether the metabolism of HP- ^{13}C pyruvate is sensitive to PDK inhibition. Our results showed that higher production of HP-bicarbonate via PDC in PDK deficient livers. ^{13}C NMR isotopomer analysis of tissue extracts confirms higher ^{13}C -enrichment of AcCo-A in the DKO livers than the control group. The result suggested that the appearance of HP-bicarbonate is a sensitive biomarker for monitoring the consequences of PDK inhibition.

Computer 47

[Regional Analysis of Hyperpolarized Lactate-to-Pyruvate Ratio Can Improve Sensitivity to Monitor Progression of Acute Pulmonary Inflammation](#)Mehrdad Pourfathi¹, Hooman Hamedani¹, Yi Xin¹, Stephen Kadlec¹, Maurizio Cereda², Harrilla Profka¹, Ian Duncan¹, Nicholas Drachman¹, Sarmad Siddiqui¹, Kai Ruppert¹, Joe Najji¹, and Rahim Rizzi¹

¹Radiology, University of Pennsylvania, Philadelphia, PA, United States, ²Anesthesiology and Critical Care, University of Pennsylvania, Philadelphia, PA, United States

In this hyperpolarized pyruvate imaging study of acute lung injury, we assessed alterations of regional lactate-to-pyruvate ratio during the progression of lung inflammation caused by acid aspiration. The study shows that posterior lactate-to-pyruvate ratio changes more significantly after injury compared to the anterior ratio. This is consistent with the pattern observed with proton MRI. We report good correlation between increased lactate-to-pyruvate ratio due to inflammation and increased proton image intensity as a result of formation of edema, especially in the posterior regions.

[Metabolic characterization of rat lung transplantation using HP \[1-13C\]-pyruvate MRI](#)Sarmad Siddiqui¹, Mehrdad Pourfathi¹, Andreas Habertheuer², Yi Xin¹, Harrilla Profka¹, Hooman Hamedani¹, Stephen Kadlec¹, Ali Najji², Prashanth Vallabhajosyula², and Rahim Rizzi¹

¹Radiology, University of Pennsylvania, Philadelphia, PA, United States, ²Surgery, University of Pennsylvania, Philadelphia, PA, United States

Orthotopic rat lung transplantation is a well-established animal model used for elucidating the mechanics of lung transplant surgery. However, most lung function assessment is conducted via invasive techniques. In this study, we demonstrated that hyperpolarized pyruvate MRI can be used to generate metabolic biomarkers that can be used for non-invasive lung function assessment after transplantation. In successful syngeneic lung transplants, the lactate-to-pyruvate ratio remains low in both lungs after transplant. However, in allogeneic or failed syngeneic lung transplantation, the native lung returns to baseline one week after surgery, whereas the transplanted lung shows a significant (~3-fold) increase in the lactate-to-pyruvate ratio.

[3D Whole-Brain Mapping of Cerebral Blood Flow using Velocity-Selective Pulse Trains: Evaluating Various Strategies for Background Suppression](#)Qin Qin^{1,2}

¹Johns Hopkins University, Baltimore, MD, United States, ²Kennedy Krieger Institute, Baltimore, MD, United States

Velocity-selective arterial spin labeling (VSASL) has only been realized with 2D multi-slice acquisition. ASL with 3D readout is preferred for clinical applications and background suppression technique is essential for successful implementation of segmented 3D ASL. In this study, various strategies for background suppression are evaluated for 3D VSASL which are labeled with conventional T2prep VS pulse train, and new Fourier transform based velocity-selective saturation and inversion pulse trains, respectively. The optimal 3D whole-brain VSASL protocol is compared with PCASL for mapping cerebral blood flow on normal volunteers at 3T.

[Solving the dark-sides of multiband-ASL: A framework to correct for increased motion artefacts in MB-ASL due to sharp transitions in the level of background suppression](#)Yuriko Suzuki¹, Thomas W Okell², Wouter M Teeuwisse¹, Sophie Schmid¹, Merlijn van der Plas¹, Michael A Chappell^{2,3}, and Matthias JP van Osch¹

¹C.J.Gorter Center for High Field MRI, Department of Radiology, Leiden University Medical Center, Leiden, Netherlands, ²FMRIB Centre, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom, ³Institute of Biomedical Engineering, University of Oxford, Oxford, United Kingdom

Recently, incorporation of multi-band (MB-) EPI into ASL has been reported, enabling increased spatial coverage without compromising SNR of distal slices due to longer post-labeling delay time. However, the combination of MB-EPI and ASL with the background suppression (BGS) could potentially induce problems when motion correction (MoCo) is required. In this study, we demonstrate that subtraction artefacts can be introduced when performing MoCo of MB-BGS-pCASL and that these artefacts can degrade image quality considerably. We propose a new framework that corrects for image degradation caused by MoCo of MB-BGS-pCASL data, thereby greatly improving robustness and thus usefulness of MB-BGS-pCASL.

Improved spatial encoding for vessel-selective pCASL: improving efficiency, minimising mis-labeling, and shortening scan-time for artery specific MRA

Yuriko Suzuki¹, Matthias JP van Osch¹, and Thomas W Okell²

¹C.J.Gorter Center for High Field MRI, Department of Radiology, Leiden University Medical Center, Leiden, Netherlands, ²FMRIB Centre, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom

Hadamard-encoded vessel-encoded pCASL is a vessel-selective ASL technique that enables SNR-efficient vascular territory mapping for perfusion MRI. For vessel-selective ASL-MRA, however, minimising the number of encodings is necessary to achieve clinically feasible scan times. The spatial modulation of inversion in ve-pCASL is gradual, which could potentially reduce SNR-efficiency and cause mislabeling of arteries when reducing the number of encodings. In this study, the modulation of ve-pCASL was optimized to achieve sharper inversion to avoid signal contamination of non-targeted arteries and achieve 4D-MRA with a minimal number of Hadamard-encodings.

Bayesian model selection of Time Encoded Arterial Spin Labelling: effect of T1 and dispersion

Marco Castellaro¹, Erica Silvestri¹, Ilaria Boscolo Galazzo², Matteo Tonietto¹, Alessandro Palombi¹, Francesca Benedetta Pizzini², Stefania Montemezzi², Enrico Grisan¹, Matthias J.P. Van Osch³, and Alessandra Bertoldo¹

¹Department of Information Engineering, University of Padova, Padova, Italy, ²University of Verona, Verona, Italy, ³Radiology, LUMC, Gorter Center for high field MRI, Leiden, Netherlands

Time-Encoded Arterial Spin Labelling (TE-ASL) has been proposed as a tool to efficiently sample the kinetics of the ASL signal. We propose a model comparison based on Bayesian Model Selection (BMS), to provide insights on which is the optimal model for the quantification of TE-ASL. Our results show how important it is to consider both T₁ decay and dispersion in the quantification process. When mainly interested in GM, it is advisable to incorporate the dispersion of the bolus in the model with a Gamma kernel dispersion model and to use a single T₁ value of 1.3s.

Computer 54

Defining the optimal post-labeling delay for pCASL using patient specific estimates of blood velocity in the carotid artery

Neville D Gai¹ and John A Butman¹

¹Radiology & Imaging Sciences, NIH Clinical Center, Bethesda, MD, United States

Pseudo-continuous arterial spin labeling (pCASL) with 3D non-segmented acquisition scheme allows assessment of full brain CBF with sufficiently high SNR and resolution in an efficient manner. Post-labeling delay is a critical parameter which needs to be determined preferably on a per subject basis since PLD can change based on the physiological condition of a subject. Multiple post-labeling delay (PLD) pCASL could address this issue. However, multiple PLD pCASL is not feasible for the 3D non-segmented acquisition scheme. In this work, we related the velocity in carotid artery (CA) measured using two schemes to PLD in ten volunteers. A relationship between the CA velocity and optimal PLD was derived which allows for optimal PLD to be determined on the fly for each subject.

Improved Calculation of Arterial Blood Equilibrium Magnetization in Arterial Spin LabelingAndré Ahlgren¹, Ronnie Wirestam¹, Freddy Ståhlberg^{1,2,3}, Linda Knutsson^{1,4}, and Esben Thade Petersen⁵

¹Department of Medical Radiation Physics, Lund University, Lund, Sweden, ²Diagnostic Radiology, Lund University, Lund, Sweden, ³Lund University Bioimaging Center, Lund University, Lund, Sweden, ⁴Department of Radiology (Adjunct), Johns Hopkins School of Medicine, Baltimore, United States, ⁵Danish Research Centre for Magnetic Resonance, Copenhagen University Hospital Hvidovre, Copenhagen, Denmark

The calibration factor (equilibrium magnetization of arterial blood) in arterial spin labeling is usually calculated by dividing a PD image with a constant brain-blood partition coefficient, λ . A more accurate approach would be to divide a map corresponding to the PD of the perfused parenchymal tissue with a λ map (i.e. taking into account different values of λ in different tissue types). In this work, we demonstrate how this can be achieved using partial volume (PV) estimates. In vivo results are demonstrated and compared with the conventional method.

3623

Computer 57

The influence of acquisition parameters on CBF and BOLD sensitivity in 3 and 7 Tesla ASL fMRIAnna Gardumi¹, Dimo Ivanov¹, Roy Haast¹, Josef Pfeuffer², Benedikt A Poser¹, and Kamil Uludag¹

¹Maastricht University, Maastricht, Netherlands, ²Application Development, Siemens, Erlangen, Germany

Arterial spin labeling (ASL) measures cerebral blood flow (CBF) non-invasively. Compared to the BOLD signal, CBF is quantitative and more directly linked to neural activation, albeit with lower SNR. Due to increased SNR and T1 relaxation time, ultra-high field MRI promises benefits for ASL. However, technical challenges remain to exploit its full potential. Here, we compared 3T and 7T ASL implementations and studied the influence of labeling schemes, resolution, parallel imaging, and field strength on the CBF and BOLD functional contrast. We found 3T pCASL being advantageous for low-resolution and 7T FAIR for high-resolution and acquisitions utilizing parallel imaging.

Automatic Planning for fast and robust Flow Territory MappingMichael Helle¹, Kim van de Ven², and Fabian Wenzel¹

¹Philips Research, Hamburg, Germany, ²Philips Healthcare, Best, Netherlands

Super-Selective Pseudo-continuous Arterial Spin Labeling (pCASL) requires the labeling focus to be optimized to each artery of interest individually. This might be time-consuming especially for inexperienced users, and suboptimal results are possible as the labeling efficiency depends on the location of the labeling spot, as well as its angulation, which should be perpendicular to the artery. This study demonstrates an automatic planning approach for Super-Selective pCASL measurements in the major brain feeding vessels and subsequently compares the results to images acquired using a manual positioning of the labeling spot.

3626

Computer 60

A multi-compartment cerebral perfusion phantom to test territory selection using vessel encoded arterial spin labellingMichael A Chappell¹, Bridget Fryer¹, Anton Firth¹, Robert Wight¹, Thomas Kirk¹, and Thomas W Okell²

¹Institute of Biomedical Engineering, University of Oxford, Oxford, United Kingdom, ²Oxford Centre for Functional MRI of the Brain, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom

Vessel encoded arterial spin labelling allows the visualisation of perfusion territories in the brain. However, the accuracy of perfusion measurements from VE-ASL and the associated analysis methods is difficult to establish without ground truth. Perfusion phantom devices have been prosed for conventional ASL, but don't currently attempt to model the full cerebral vasculature anatomy of the brain, limiting their value in evaluation of VE-ASL methods. Thus in this work we set out to create a multi-compartment, multi 'artery' perfusion phantom based on normal vascular anatomy.

3627

Computer 61

Evaluation of 3D GRASE and 2D MB-EPI for Multi-Delay PCASL ImagingXiufeng Li¹, Xingfeng Shao², Dingxin Wang^{1,3}, Sudhir Ramanna¹, Steen Moeller¹, Kamil Ugurbil¹, Essa Yacoub¹, and Danny J.J. Wang²

¹Radiology-CMRR, University of Minnesota, Minneapolis, MN, United States, ²Laboratory of FMRI Technology, Stevens Neuroimaging and Informatics Institute, University of Southern California, CA, United States, ³Siemens Medical Solutions USA Inc., MN, United States

Recently 2D multi-band (MB) imaging has emerged as a promising alternative to 3D acquisitions for arterial spin labeling imaging. As part of the Human Connectome Project, we evaluated a segmented 3D GRASE and 2D MB-EPI for multi-delay PCASL imaging in terms of test-retest repeatability and CBF/ATT quantification. The results indicated that compared to 3D GRASE, 2D MB-EPI is less sensitive to subject motion, provided comparable but more reproducible ATT and CBF estimates, and suffered less from data loss. 2D MB-EPI appears promising for multi-delay PCASL imaging, especially with limited imaging time and where higher spatial resolution is of interest.

3628

Computer 62

Robust 3D pCASL perfusion imaging using a Cartesian Acquisition with Spiral Reordering (CASPR)Joshua S. Greer^{1,2}, Xinzeng Wang², Marco C. Pinho^{2,3}, Ivan Pedrosa^{2,3}, and Ananth J. Madhuranthakam^{2,3}

¹Bioengineering, UT Dallas, Richardson, TX, United States, ²Radiology, UT Southwestern Medical Center, Dallas, TX, United States, ³Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, TX, United States

Arterial spin labeling can non-invasively measure perfusion, but offers low SNR compared to contrast-enhanced perfusion techniques. A novel 3D TSE with a Cartesian Acquisition with SPiral Reordering (CASPR) was implemented and combined with pCASL in the brain and kidneys. This sampling technique samples the center of k-space early in each echo train, and was shown to provide significantly improved 3D perfusion images compared to 3D linear acquisitions, and more extensive coverage than 2D acquisitions in a similar scan time.

3629

Computer 63

Single shot high resolution 3D arterial spin labeling using 2D CAIPI and ESPIRiT reconstruction

Xingfeng Shao¹ and Danny JJ Wang¹

¹Laboratory of fMRI Technology (LOFT), Mark & Mary Stevens Neuroimaging and Informatics Institute, Keck School of Medicine, University of Southern California, Los Angeles, CA, United States

We present a single-shot 3D GRASE pCASL technique, which reduces the data loss due to motion, using 2D CAIPI sampling strategy, and reconstruct the under-sampled data using ESPIRiT. Proposed sequence employs 4-fold acceleration and achieves whole brain volume with isotropic $3 \times 3 \times 3 \text{ mm}^3$ resolution. This technique was successfully applied for high resolution multi-delay ASL imaging, and CBF, ATT and T1 map could be simultaneously calculated in 4 min 14 sec.

3630

Computer 64

2D CAIPIRINHA improves accelerated 3D GRASE ASL

Dimo Ivanov¹, Josef Pfeuffer², Anna Gardumi¹, Kâmil Uludağ¹, and Benedikt A Poser¹

¹Department of Cognitive Neuroscience, Maastricht University, Maastricht, Netherlands, ²MR Application Development, Siemens Healthcare, Erlangen, Germany

Arterial spin labelling (ASL) is the primary non-invasive MRI approach to measure cerebral blood flow in healthy subjects and patients. Recently, a consensus paper has recommended segmented versions of 3D spin-echo readouts like GRASE, but these are susceptible to motion and have poor temporal resolution. To alleviate these drawbacks, we propose to accelerate the 3D GRASE readout and utilize 2D CAIPIRINHA for the reconstruction. We demonstrate that our approach is superior or at least equivalent to the 2D GRAPPA technique, depending on the acceleration factor used. The proposed approach will particularly benefit functional and clinical ASL applications.

3631

Computer 65

A Deconvolution Method for Improved CBF Quantification in 3D-GRASE ASL

Kenneth Wengler^{1,2} and Xiang He²

¹Biomedical Engineering, Stony Brook University, Stony Brook, NY, United States, ²Radiology, Stony Brook University, Stony Brook, NY, United States

Pseudo-continuous arterial spin labeling (pCASL) with segmented 3D-GRASE acquisition is widely accepted as the optimal ASL technique. However, the method suffers from blurring along the partition direction caused by point spread function (PSF) broadening. In this study, a PSF deconvolution method for pCASL images with 3D-GRASE acquisition is developed and evaluated in simulations and in-vivo experiments. The deconvolution method greatly reduces the effects of the PSF and recover the perfusion signal for segmentation factors of at least $2_{\text{PAR}} \times 2_{\text{PE}}$. The proposed deconvolution method improves the accuracy of cerebral blood flow quantification and facilitates the use of lower segmentation factors.

3632

Computer 66

Optimization of Flip Angle Design for Reduced T2 Blurring of 3D Arterial Spin Labeling

Li Zhao¹ and David Alsop¹

¹Radiology, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, United States

Conventional 3D arterial spin labeling images suffer from pronounced T2 blurring. In this work, new variable flip angle schemes, which can provide a Hann or Fermi window response across the slice direction, or which can be easily corrected to the designed window response and provide optimal SNR, were evaluated. Volunteers' results show reduced blurring, improved SNR and contrast with the proposed methods.

3633

Computer 67

A denoising method for arterial spin labeling data based on total generalized variation (TGV) with a spatial varying regularization parameter

Stefan Manfred Spann¹, Kamil S Kazimierski-Hentschel², Christoph Stefan Aigner¹, and Rudolf Stollberger^{1,3}

¹Institute of Medical Engineering, Graz University of Technology, Graz, Austria, ²Institute for Mathematics and Scientific Computing, University of Graz, Graz, Austria, ³BioTechMed-Graz, Graz, Austria

Arterial spin labeling perfusion imaging permits a noninvasive approach to measure cerebral blood flow. The poor SNR of this technique makes denoising essential. ASL images are often corrupted with motion, physiological or scanning artifacts or acquired using parallel imaging leading to spatial dependent noise. To account for those artifacts and spatial varying noise we propose a denoising approach based on total generalized variation (TGV) using a spatial dependent regularization parameter. The performance of the proposed technique is evaluated on synthetic and in-vivo data and compared with the non-local means combined dual-tree complex wavelet transform (DT-CWT) denoising method.

A Spatio-temporal Denoising Approach based on Total Variation Regularization for Arterial Spin Labeling

Cagdas Ulas^{1,2}, Stephan Kaczmarz³, Christine Preibisch³, Jonathan I. Sperl², Marion I. Menzel², Axel Haase⁴, and Bjoern H. Menze¹

¹Department of Computer Science, Technische Universität München, Munich, Germany, ²GE Global Research, Munich, Germany, ³Department of Neuroradiology, Technische Universität München, Munich, Germany, ⁴Zentralinstitut für Medizintechnik, Technische Universität München, Munich, Germany

We present a new spatio-temporal denoising method for arterial spin labelling MR image repetitions, and mainly aim to improve the quality of perfusion-weighted images and cerebral blood flow (CBF) maps obtained from a subset of all dynamics available. Our technique is based on a two-step 3D total variation regularization, which is applied to subsets of control/label pairs in the first step and to resulting perfusion-weighted (difference) images in the second step. We demonstrate that our method leads to improved quality of perfusion-weighted images and CBF maps compared to existing spatial filtering techniques in short computation time.

3635

Computer 69

The effect of post-labeling delay on multiband pCASL based functional connectivity

Alexander D. Cohen¹, Andrew S. Nencka¹, and Yang Wang¹

¹Radiology, Medical College of Wisconsin, Milwaukee, WI, United States

When too short a post-labeling delay (PLD) is used for ASL, intravascular artifacts can be present. This issue is amplified in multiband (MB) ASL where superior slices are acquired early in the acquisition. Here, MB pseudocontinuous ASL (pCASL) and a dual regression approach were used to analyze functional connectivity with PLD=1000ms and 1525ms. Increased whole-brain tSNR was observed for the PLD=1000ms data, but intravascular signal was present. Group connectivity was similar between PLDs, and no significant differences in mean or max z-score were seen between PLD. Thus, shorter PLDs may be appropriate for MB-ASL rsfMRI despite the presence of intravascular artifacts.

3636

Computer 70

Functional connectivity mapping using 3D GRASE arterial spin labeling MRI

Kalen J. Petersen¹, Daniel O. Claassen², and Manus J. Donahue³

¹Chemical and Physical Biology, Vanderbilt, Nashville, TN, United States, ²Neurology, Vanderbilt, ³Radiology, Vanderbilt

The overall goal of this work is to optimize arterial spin labeling (ASL) MRI techniques to enable the use of baseline cerebral blood flow (CBF) fluctuations to identify major intrinsically-connected resting state networks (RSNs). We provide data in support of 3D GRASE pCASL being able to provide similar functional resting state networks as BOLD. Additionally, extremely low-frequency fluctuations, less than 0.01 Hz, were present in the CBF-weighted pCASL data, suggesting that application of pCASL may provide additional functional information relative to BOLD, which generally requires low-frequency filtering.

Assessment of Resting State Perfusion and Coherent Large-Scale Brain Networks in Healthy Aging Using Arterial Spin Labeling Perfusion MRI

Alvaro Galiano¹, Reyes García de Eulate¹, Marta Vidorreta², Miriam Recio³, and María Fernández-Seara^{1,4}

¹Radiology, University of Navarra Hospital, Pamplona, Spain, ²Center for Functional Neuroimaging, University of Pennsylvania, Philadelphia, United States, ³Neurology, University of Navarra Hospital, Pamplona, Spain, ⁴Biomedical Engineering, TECNUN, University of Navarra, San Sebastian, Spain

Cognitive decline is associated with aging even in the absence of disease. In this study ASL perfusion fMRI was used to investigate changes in perfusion and resting state networks connectivity due to aging, by comparing two groups of healthy subjects (young and elderly). Results showed perfusion deficits in the elderly group, in association areas, related with advanced cognitive abilities. Disruptions in various core RSNs were also detected. Assessment of perfusion and resting functional connectivity jointly could be a good predictor of cognitive decline and a good biomarker for treatments aiming to extend cognitive abilities.

Trait Specificity of Regional Cerebral Blood Flow between Different Resting-State Conditions

Zhengjun Li¹, Marta Vidorreta¹, Daniel Wolf², and John A. Detre¹

¹Dept. of Neurology, University of Pennsylvania, Philadelphia, PA, United States, ²Dept. of Psychiatry, University of Pennsylvania, Philadelphia, PA, United States

We used latent state-trait theory to examine trait specificity of regional cerebral blood flow (CBF) acquired using arterial spin labeled (ASL) perfusion MRI in four different resting-state conditions (eyes-open, eyes-closed, fixation, and a low-level attention task (psychomotor vigilance task, PVT)). Most brain regions accepted the latent state-trait model. Fixation exhibited the lowest latent trait specificity, while PVT, eyes-open, and eyes-closed showed progressively higher trait specificity. We confirmed that ASL CBF shows trait-like properties, which are optimally fit using eyes-open or eyes-closed conditions.

Investigating the relation between electrical conduction and tissue composition with proton and sodium MRI

Stefano Mandija¹, Paul W de Bruin², Andrew G Webb², Peter R Luijten¹, and Cornelis AT van den Berg¹

¹Center for Image Sciences, Center for Image Sciences, UMC Utrecht, Utrecht, Netherlands, ²Radiology, Gorter Center for High-field MRI, LUMC Leiden, Leiden, Netherlands

The focus of the presented work is to understand the relation between electrical conductivity and tissue composition in terms of ^{23}Na concentration and water fraction. This would be relevant to evaluate the potential value of electrical conductivity imaging as a new endogenous biomarker and the validity of accessing conductivity from water content. For this purpose, MR-EPT and waterEPT conductivity reconstructions are performed and compared to network analyzer measurements. To evaluate whether conductivity is directly related to the total sodium concentration in free water, ^{23}Na images are acquired at 7T and conductivity reconstruction are then performed using the Stogryn's model.

Computer 74

CONtrast Conformed Electrical Properties Tomography (CONCEPT) based on Multi-channel Transmission

Yicun Wang¹, Pierre-Francois Van de Moortele², and Bin He^{1,3}

¹Department of Biomedical Engineering, University of Minnesota, Minneapolis, MN, United States, ²Center for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN, United States, ³Institute for Engineering in Medicine, University of Minnesota, Minneapolis, MN, United States

Magnetic Resonance based Electrical Properties Tomography holds promise to provide valuable information on tissue functional changes, such as Tumorigenesis. We propose a novel technique based on multi-channel transmission to reconstruct quantitative electrical properties maps by exploiting the intermediate contrast information with jointly promoted sparsity. The resultant optimization problem was solved by Alternating Direction Method of Multipliers within seconds. Numerical simulations, phantom and human subject experiments were performed at 7T using a multi-channel transceiver coils array, demonstrating improved accuracy and visual outcome. CONCEPT does not rely on anatomical assumptions, and therefore represents a general approach suitable for broader applications.

Computer 75

Dictionary-based Electric Properties Tomography

Ulrich Katscher¹, Max Herrmann¹, Christian Findeklee¹, Mariya Doneva¹, and Thomas Amthor¹

¹Philips Research Europe, Hamburg, Germany

Electric Properties Tomography (EPT) derives tissue conductivity and permittivity according to the Helmholtz equation via the second derivative of the measured complex B1 map, or by iteratively solving the corresponding forward problem. This abstract presents a different type of EPT reconstruction: the measured B1 map is compared locally with entries of a dictionary, which are small B1 maps of a priori known electric properties. This "dictionary-based EPT" (db-EPT) could be able to solve the transceive phase problem as well as the boundary problem of EPT. This study applies db-EPT to numerical and experimental data comparing different types of dictionaries.

Computer 76

Spatial and Contrast Resolution of Phase Based MREPT

Yusuf Ziya Ider¹, Gokhan Arıturk¹, and Gulsah Yildiz¹

¹Electrical and Electronics Engineering, Bilkent University, Ankara, Turkey

Clarification of the contrast resolution (CR) and spatial resolution (SR) limits of phase based MREPT for conductivity imaging is essential for assessing its success in clinical applications. Noise analysis of conventional phase based MREPT is performed to find the SNR needed for the MR sequence used for measuring B1-phase. It is found that with 1000-2000 SNR values about 0.01 S/m CR can be achieved. For SR evaluation, generalized phase based MREPT, which does not suffer from internal boundary artefacts, is considered. It is found by phantom experiments that 3.5mm spatial resolution is easily obtained with the state-of-art MR methods.

Computer 77

Adaptive Weighted Polynomial fitting in phase-based Electrical Property Tomography

Jun-Hyeong Kim¹, Jaewook Shin¹, Ho-Joon Lee², Kang-Hyun Ryu¹, and Donghyun Kim¹

¹Department of Electrical and Electronic Engineering, Yonsei University, Seoul, Korea, Republic of, ²Department of Radiology and Research Institute of Radiological Science, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of

Weighted polynomial fitting method was proposed to resolve boundary artifact and noise amplification of Electrical Property Tomography. Weighted polynomial fitting method employs T1/T2 tissue contrast as prior information under assumption that pixels with similar magnitude intensity have similar conductivity. However, for non-simply connected structures make the fitting inaccurate. Therefore, in this study, we propose a modified weighted polynomial fitting technique including spatial constraint.

Computer 78

Current Density Measurements in the Brain using Magnetic Resonance Electrical Impedance Tomography in Healthy Volunteers

Aditya Kumar Kasinadhuni¹, Aprinda Indahlastari², Kevin Castellano³, Christopher Saar⁴, Casey Weigel⁴, Bakir Mousa⁴, Michael Schär⁵, Munish Chauhan², Thomas Harold Mareci⁶, and Rosalind Jane Sadleir²

Characterizing current density distributions in the brain of healthy volunteers can provide important information to guide electrical stimulation therapies. Current-induced magnetic fields, produced as a result of electrical stimulation, can be mapped from phase changes in the MR imaging then current density can be computed using Maxwell's equations. In this study, we present the first current density distribution induced magnetic field maps in healthy volunteers resulting from electrical stimulation using low frequency (10 Hz) transcranial alternating current simulation (TACS).

In Vivo Mapping of Liver Tissue Damage using MR-based Conductivity Imaging Method

Bup Kyung Choi¹, Nitish Katoch¹, Saurav ZK Sajib¹, Jin Woong Kim², Hyung Joong Kim¹, Oh In Kwon³, and Eung Je Woo¹

¹Kyung Hee University, Seoul, Korea, Republic of, ²Radiology, Chonnam National University Medical School, Gwangju, Korea, Republic of, ³Konkuk University, Seoul, Korea, Republic of

Liver tissues mainly consist of single cell, the variations of ion concentration and mobility inside the liver have similar pattern. This indicates that liver tissues can exhibit uniform distribution of electromagnetic tissue properties such as electrical conductivity. MREIT is typical method which can provide electrical conductivity information of suspicious tissue using a current-injection MRI method. Mapping of liver tissue damage using MREIT conductivity imaging may provide direct, immediate, and high sensitive information based on the changes of ion concentration and mobility at cellular levels. This study experimentally imaged *in vivo* liver tissue damage based on the changes of tissue conductivity.

Volumetric Reconstruction of Tissue Electrical Properties from B1+ and MR Signals Using Global Maxwell Tomography: Theory and Simulation Results.

Jose E. C. Serralles¹, Ioannis Georgakis², Athanasios G. Polimeridis², Luca Daniel¹, Jacob K. White¹, Daniel K. Sodickson^{3,4}, and Riccardo Lattanzi^{3,4}

¹Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, MA, United States, ²Center for Computational and Data-Intensive Science and Engineering, Skolkovo Institute of Science and Technology, Moscow, Russian Federation, ³The Sackler Institute of Graduate Biomedical Science, New York University School of Medicine, New York, NY, United States, ⁴Center for Advanced Imaging Innovation and Research, New York University School of Medicine, New York, NY, United States

Magnetic resonance-based inverse scattering has been proposed to extract tissue electrical properties (EP). We present an improved implementation of the Global Maxwell Tomography (GMT) EP mapping technique, with two new cost functions and an extension that uses piecewise linear basis functions to represent fields for higher accuracy. GMT does not make symmetry assumptions, is fully 3D, and is robust to noise. We validated the new GMT version with various numerical experiments, using a heterogeneous head model with realistic EP and a phantom with tissue-mimicking EP. We showed, for the first time, that artifact-free accurate reconstruction of EP is possible.

3648

Longitudinal Atlas Construction for Normative Human Brain Development and Aging over the Lifespan using Quantitative Susceptibility Mapping (QSM)

Yuyao Zhang¹, Hongjiang Wei¹, Naying He², Christian Langkammer³, Stefan Ropele³, Fuhua Yan², and Chunlei Liu¹

¹University of California, Berkeley, Berkeley, CA, United States, ²Department of Radiology, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, People's Republic of China, ³Department of Neurology, Medical University of Graz, Graz, Austria

QSM is able to provide high contrast for iron-rich deep-brain nucleus. This is attributed to the sensitivity of magnetic susceptibility to the spatial variations of cellular components that exhibit different magnetic susceptibility properties, especially for brain iron and myelin. Although there have been atlases proposed for certain age groups, a longitudinal statistical atlas construction from general healthy population based on QSM is still lacking. We constructed longitudinal QSM atlases over the whole lifespan (from 1 to 83 years-old). One common QSM atlas is built for every 10-years interval to demonstrate the unique age-specific morphology and appearance of human brains.

Computer 83

Does Total Iron Content in Deep Brain Nuclei Really Increase in Healthy Aging? A Study Based on Quantitative Susceptibility Mapping.

Yuyao Zhang¹, Hongjiang Wei¹, Naying He², Fuhua Yan², and Chunlei Liu¹

¹University of California, Berkeley, Berkeley, CA, United States, ²Department of Radiology, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, People's Republic of China

The crucial role of iron for normal neurological function in human brain has been well recognized. The iron concentration evolution trajectories in human brain deep nucleus have been shown monotonously increased with aging. However, previous studies concern only on iron concentration. At the same time, atrophy occurs in healthy ageing brains. These two competing effects raise an interesting possibility that the total iron content in deep brain nuclei may decrease. Surprisingly, the iron content, investigated by QSM, in globus pallidus, substantia nigra and red nuclei appear to decrease after the iron content reaching a peak.

Computer 85

Importance of reference in QSM and a new differential ROI reference method

TaeHyun Hwang¹, JinGu Lee¹, JunYeol Choi¹, SangJoon Kim², GeonHo Jahng³, and Jongho Lee¹

¹Department of Electrical and Computer Engineering, Seoul National University, Seoul, Korea, Republic of, ²Department of Radiology, ASAN Medical Center, Korea, Republic of, ³Department of Radiology, Kyung Hee University Hospital at Gangdong, Korea, Republic of

In this study, we developed a computer simulation to demonstrate the importance of reference in QSM. The results show that QSM values are substantially affected by spatial coverage for reconstruction. Only when the data are referenced using a neighboring region, the QSM results provide correct susceptibility values. Additionally, we suggest a new "differential ROI" reference method. This approach reports the susceptibility value as a difference between two (neighboring) ROIs. We demonstrate this new approach for a Parkinson's disease patient study.

Computer 86

Quantitative susceptibility mapping with separate calculation in water and fat regions

Ryota Sato¹, Toru Shirai¹, Yo Taniguchi¹, Takenori Murase², Atsushi Kuratani², Taisei Ueda², Takashi Tsuneki², Yoshitaka Bito², Hisaaki Ochi¹, and Yoshihisa Soutome¹

¹Research and Development Group, Hitachi, Ltd., Tokyo, Japan, ²Healthcare Business Unit, Hitachi, Ltd., Tokyo, Japan

To reduce the calculation error and artifacts of susceptibility in the boundary region between water and fat, a new reconstruction method is presented and applied to a prostate QSM. In the proposed method, susceptibility maps of the water region and the fat region are calculated separately and differently and then combined. Numerical simulation and human prostate imaging using a 3T-MRI are performed to evaluate accuracy and artifacts of the proposed method. The results suggest that the proposed method reduces calculation error and the shading artifacts in the boundary region between water and fat near the prostate.

Post-implant dosimetry is an important quality assurance for prostate low-dose-rate (LDR) permanent seed brachytherapy. Despite the superior soft tissue contrast in MRI that is required for tumor delineation, there are some unresolved issues with seed depiction on MR images as they appear as signal void. In addition, calcified regions have similar characteristics on MR images making them indiscernible. This work investigates the feasibility of an MR-only workflow based on quantitative susceptibility mapping (QSM) and 3D k-means clustering for post-implant localization of the seeds.

In-vivo phase imaging of growing epiphyseal human cartilage at 7 T.

Barbara Dymerska¹, Klaus Bohndorf¹, Paul Schennach¹, Alexander Rauscher², Siegfried Trattnig¹, and Simon Daniel Robinson¹

¹High Field MR Centre, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria, ²UBC MRI Research Centre, University of British Columbia, Vancouver, Canada

Growing epiphyseal cartilage of children contains vessels and more complex layer structure than adult hyaline cartilage. Phase imaging is sensitive to deoxyhemoglobin in venous blood and to orientation of magnetic tissues, but it is challenging since many established methods for combining and unwrapping data fail in the thin cartilage of the knee. In this study different phase reconstruction methods were tested at 7T and high resolution SWI was applied to visualize veins and collagen fiber architecture in healthy young subjects.

3656

Computer 90

Comparison of quantitative susceptibility mapping methods for evaluating cerebral microbleeds at 3T and 7T

Yicheng Chen¹, Clare B Poynton², Suchandrima Banerjee³, and Janine M Lupo²

¹UC Berkeley-UCSF Graduate Program in Bioengineering, University of California, Berkeley and University of California, San Francisco, San Francisco, CA, United States, ²Department of Radiology, University of California, San Francisco, San Francisco, ³Global Applied Science Laboratory, GE Healthcare

There is a growing interest in using QSM to detect and quantitatively evaluate cerebral microbleeds (CMBs). We compared several algorithms proposed in recent years for QSM on patients with CMBs after radiation therapy at 3T and 7T by quantitatively analyzing the noise and contrast of the susceptibility maps. Although RESHARP+ iLSQR had the least noise among methods, CMB and vessel contrast were more affected by incomplete background field removal, especially at 7T.

3657

Computer 91

Quantitative susceptibility mapping: phase images and microstructure

Lukas R Buschle^{1,2}, Christian H Ziener¹, Michael O Breckwoldt², Artur Hahn², Julia Bode³, Björn Tews³, Martin Bendszus², Heinz-Peter Schlemmer¹, and Felix T Kurz^{1,2}

¹E010 Radiology, German Cancer Research Center, Heidelberg, Germany, ²Neuroradiology, University Hospital Heidelberg, Heidelberg, Germany, ³Schaller Research Group, University of Heidelberg and German Cancer Research Center, Heidelberg, Germany

In this work, the effect of inhomogeneous microstructure on quantitative susceptibility mapping (QSM) is simulated for typical microstructural geometries. The results suggest that the susceptibility of blood-filled capillaries can not be measured using quantitative susceptibility mapping due to the symmetry of the local Larmor frequency around a capillary. However, numerical simulations show that the concentration of spherically-shaped magnetic particles (contrast agents) is determinable with QSM. These results are therefore essential for a detailed analysis of quantitative susceptibility images.

3658

Computer 92

Variation of Regions of Interest (ROIs) using different tools for automatic ROI generation: The impact on reported magnetic susceptibility values in QSM

Emma Dixon¹, David L Thomas², Anna Barnes³, and Karin Shmueli¹

¹Medical Physics and Biomedical Engineering, University College London, London, United Kingdom, ²Leonard Wolfson Experimental Neurology Centre, University College London, Institute of Neurology, United Kingdom, ³Institute of Nuclear Medicine, UCLH-NHS Foundation Trust, United Kingdom

Automatic Region of Interest (ROI) generation is useful for large clinical studies using Quantitative Susceptibility Mapping (QSM) as this allows mean susceptibility values for anatomical regions to be reported without manual intervention.

Several methods to generate ROIs are compared in this work. We found that methods based on T1 contrast showed little variation whether a typical magnitude image from a susceptibility protocol or a structural MPRAGE image was used. An additional method based on a QSM atlas showed greater variability in ROIs.

Mean susceptibility values for ROIs were shown to vary greatly depending on the method used to generate ROIs.

3659

Computer 93

Positive visualization of MR compatible nitinol stent using a susceptibility-based imaging method

Caiyun Shi¹, Xiaoyong Zhang^{1,2}, Shi Su¹, Hairong Zheng¹, Xin Liu¹, Guoxi Xie^{1,3}, and Jim Ji⁴

¹Shenzhen Key Laboratory for MRI, Lauterbur Research Center for Biomedical Imaging, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, People's Republic of China, ²Centers for Biomedical Engineering, College of Information Science and Technology, University of Science and Technology of China, Hefei, People's Republic of China, ³Beijing Center for Mathematics and Information Interdisciplinary Sciences, Beijing, People's Republic of China, ⁴Department of Electrical and Computer Engineering, Texas A&M University, TX, United States

Previous studies have demonstrated that a susceptibility-based positive contrast MR method exhibits excellent efficacy for visualizing MR compatible metal devices by taking advantage of their high magnetic susceptibility. However, the method was not evaluated in the visualization of stents. Therefore, the purpose of this study is to assess whether the susceptibility-based positive method can be used to visualize the nitinol stents, with the comparison of two typical MR positive contrast techniques, i.e., SUMO and GRASP. Experiment results showed that the susceptibility-based method provides much better visualization and localization of the stent than SUMO and GRASP.

3660

Computer 94

Magnetic Properties of Skeletal Muscle at 7T

Benjamin Tendler¹ and Richard Bowtell¹

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom

The magnetic properties of skeletal muscle tissue were examined in a phantom consisting of a piece of muscle tissue embedded in agar. Frequency perturbation maps were generated from phase maps measured at 7T, with the phantom oriented at 29 angles to the external magnetic field. Using a novel minimisation technique, susceptibility and chemical exchange properties of the muscle tissue were obtained simultaneously. From this it was determined that skeletal muscle is significantly more diamagnetic than agar; there is a small anisotropic susceptibility component and a large, orientation independent positive offset within the tissue, hypothesised to be due to chemical exchange.

3661

Computer 95

Correlations of SWI, QSM, and R2* map with neuromelanin and iron distributions from post-mortem human substantia nigra samples.

Hansol Lee¹, Se Young Chun², Jae-Hyeok Lee³, Sun-Yong Baek⁴, and HyungJoon Cho¹

¹Department of Biomedical Engineering, Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of, ²Department of Electrical and Computer Engineering, Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of, ³Department of Neurology, Pusan National University Yangsan Hospital, ⁴Department of Anatomy, Pusan National University School of Medicine, Yangsan, Korea, Republic of

Spatial characterizations of neuromelanin and iron contents in human substantia nigra provide critical information in diagnosing and treating Parkinson's disease. In this work, MR investigations of susceptibility weighted imaging (SWI), R_2^* mapping, and quantitative susceptibility mapping (QSM) were performed with three post-mortem human substantia nigra samples at 7T and correlated with corresponding histological slides. Magnetization transfer (MT) based T1-weighted MRI technique was also conducted to validate its reputed neuromelanin sensitivity as well.

3662

Computer 96

Changes in brain iron concentration after exposure to high altitude hypoxia by quantitative susceptibility mapping

Lin Chen¹, Congbo Cai², Tianhe Yang³, Jianzhong Lin³, Shuhui Cai¹, Jiaying Zhang⁴, and Zhong Chen¹

¹Department of Electronic Science, Xiamen University, Xiamen, People's Republic of China, ²Department of Communication Engineering, Xiamen University, Xiamen, People's Republic of China, ³Zhongshan Hospital, Xiamen, People's Republic of China, ⁴Department of Physiology and Neurobiology, Xiamen University, Xiamen, People's Republic of China

Environmental factors may influence brain iron concentration. We investigated the changes of magnetic susceptibility and R_2^* values of cerebral regions especially in six deep gray matter nuclei of twenty-nine participants after high altitude exposure for four weeks. The results show that the susceptibility values of gray matter, especially in caudate nucleus, putamen, globus pallidus, substantia nigra, red nucleus, increased significantly. Traditional R_2^* maps verify the results of QSM evaluation except in red nucleus. Therefore, high altitude hypoxia can lead to significant increase of cerebral iron concentration.

Optimization of Preconditioned Total Field Inversion for Whole head QSM and Cardiac QSM

Zhe Liu^{1,2}, Yan Wen^{1,2}, Pascal Spincemaille², and Yi Wang^{1,2}

¹Meinig School of Biomedical Engineering, Cornell University, Ithaca, NY, United States, ²Department of Radiology, Weill Cornell Medical College, New York, NY, United States

Preconditioned Total Field Inversion (TFI) allows QSM for the entire head and chest. The preconditioner determines the TFI convergence. Can we choose a preconditioner that maximizes QSM quality within limited computational time? To answer this question, we conducted two numerical simulations specific to these applications to search for an optimal preconditioner. We found that preconditioner too small or too big for a targeted susceptibility distribution would have less computational acceleration and consequently greater errors for a given computational time. Our results here suggest that the optimal preconditioner should be identified to match the image content.

3664

Computer 98

QSM0 - QSM with automatic uniform CSF zero reference

Zhe Liu^{1,2}, Yihao Yao², and Yi Wang^{1,2}

¹Meinig School of Biomedical Engineering, Cornell University, Ithaca, NY, United States, ²Department of Radiology, Weill Cornell Medical College, New York, NY, United States

One challenge in Quantitative Susceptibility Mapping (QSM) identified in a recent QSM workshop is zero reference. Cerebrospinal fluid (CSF) with little cellular content has been a popular choice. However, current QSM often shows inhomogeneous CSF, which may be regarded as artifacts caused by surrounding anisotropic white matter fibers in the scalar dipole inversion. We propose a regularization of minimal CSF variation for projecting out CSF inhomogeneity artifacts. Our proposed new QSM incorporates automated segmentation and regularization specific to CSF and outputs susceptibility values with automatic and uniform CSF zero reference. Accordingly, we term this novel QSM method as QSM0

3665

Magnetic susceptibility in the deep gray matter varies substantially between subjects of similar age or disease state. This work employs a blind source separation technique to 239 healthy controls to determine, without prior assumptions, the spatial patterns that drive inter-subject variation of magnetic susceptibility in the human brain.

3667

Computer 101

Accelerated B_0 Mapping Using "X" Sampling in k -TE Space

Xin Miao¹, Yi Guo², Krishna S. Nayak^{1,2}, and John C. Wood^{1,3}

¹Biomedical Engineering, University of Southern California, Los Angeles, CA, United States, ²Ming Hsieh Department of Electrical Engineering, University of Southern California, Los Angeles, CA, United States, ³Division of Cardiology, Children's Hospital Los Angeles, Los Angeles, CA, United States

High-resolution B_0 mapping suffers from long scan time, and issues with phase-wraps. We present an acquisition and reconstruction technique that resolves both problems. We utilize "X" sampling in k -TE space, in which multiple phase-encoding lines are acquired exactly twice per TR. The echo spacing is shortest for central k -space and largest for outer k -space. A multi-scale reconstruction enables pixel-wise phase unwrapping. This technique may be particularly useful for quantitative susceptibility mapping (QSM), as it could a) shorten scan time while maintaining the sensitivity to high-order field variation and b) simplify phase-unwrapping, which are the key features of interest in QSM.

3668

Computer 102

Tikhonov regularization aided quantitative susceptibility mapping of whole brain without background field removal

Hongfu Sun¹, Yuhua Ma^{1,2}, M. Ethan MacDonald¹, and G. Bruce Pike^{1,2}

¹Radiology, University of Calgary, Calgary, AB, Canada, ²Biomedical Engineering, McGill University, Montreal, QC, Canada

An advanced dipole field inversion method for whole brain quantitative susceptibility mapping (QSM) without a traditional background field removal step, is proposed. To aid this ill-posed inversion process and obtain successful QSM, a Tikhonov regularization of the local susceptibility distribution is included. It is shown that the proposed method (Tikhonov-QSM) can substantially suppress reconstruction artefacts. More importantly, Tikhonov-QSM does not require edge erosion like in other QSM methods involving background field removal steps, preserving the cerebral cortex of the final images.

3669

Computer 103

A Fast Algorithm for Nonlinear QSM Reconstruction

Carlos Milovic^{1,2}, Berkin Bilgic³, Bo Zhao³, Julio Acosta-Cabronero⁴, and Cristian Tejos^{1,2}

¹Electrical Engineering, Pontificia Universidad Catolica de Chile, Santiago, Chile, ²Biomedical Imaging Center, Pontificia Universidad Catolica de Chile, Santiago, Chile, ³Martinos Center for Biomedical Imaging, Harvard Medical School, MA, United States, ⁴German Center for Neurodegenerative Diseases (DZNE), Magdeburg, Germany

This abstract presents a fast nonlinear solver for the QSM reconstruction using the total generalized variation regularization. The proposed method utilizes the alternating direction method of multipliers to obtain close-form solution to each sub-problem. To handle the non-linear data fidelity, a two-step algorithm is described, including a global optimum search and a local Newton-Raphson iteration. Compared to conventional linear solvers, nonlinear solutions reduce streaking artifacts and better handle noise in poor SNR regions. Reconstruction results are at least comparable to nonlinear MEDI in quality, but with an order of magnitude improvement in the computational efficiency.

3670

Computer 104

Effect of Poisson kernel parameters on background field removal accuracy for QSM

Debra E. Horgg^{1,2}, Samir D. Sharma¹, Scott B. Reeder^{1,2,3,4,5}, and Diego Hernando^{1,2}

¹Radiology, University of Wisconsin, Madison, WI, United States, ²Medical Physics, University of Wisconsin, Madison, WI, United States, ³Biomedical Engineering, University of Wisconsin, Madison, WI, United States, ⁴Medicine, University of Wisconsin, Madison, WI, United States, ⁵Emergency Medicine, University of Wisconsin, Madison, WI, United States

The Poisson Estimation for Ascertaining Local fields (PEAL) kernel is a recently-introduced method for background field removal in quantitative susceptibility mapping (QSM). The PEAL kernel is determined by two parameters: radius and spatial shift. The choice of these two parameters may have a substantial effect on the accuracy of background field removal. In this work, we assessed the effect of PEAL kernel size and shift on the accuracy of background field removal and susceptibility estimation.

Discrete frequency shift signatures explain GRE-MRI signal compartments

Shrinath Kadamangudi¹, Viktor Vegh¹, Surabhi Sood¹, and David Reutens¹

¹Centre for Advanced Imaging, University of Queensland, St Lucia, Australia

Ultra-high field GRE-MRI phase images present great promise for structural brain studies. Multi-echo GRE-MRI data has been shown to contain signal compartments, which may eventually be used to characterise brain microstructure. Existing studies considered three signal compartments, however it remains unclear how compartments co-localise throughout the brain. We compartmentalised the signal via frequency shift signatures in a mixture of grey-white matter brain regions and implemented quality of fit measures to select the most parsimonious model for each region. We utilised k-means cluster analyses to investigate signal compartment commonalities across different brain regions and found four dominant frequency shift signatures.

What causes streaking artifacts in QSM and how to efficiently suppress them?

Liangdong Zhou¹, Jae Kyu Choi², Youngwook Kee³, Yi Wang^{3,4}, and Jin Keun Seo¹

¹Department of Computational Science and Engineering, Yonsei University, Seoul, Korea, Republic of, ²Institute of Natural Sciences, Shanghai Jiao Tong University, Shanghai, People's Republic of China, ³Department of Radiology, Weill Cornell Medical College, New York, NY, United States, ⁴Department of Biomedical Engineering, Cornell University, New York, NY, United States

We provide a mathematical understanding for artifacts in QSM, particularly streaking artifacts. 1) The local field data can be decomposed into a dipole-compatible part and a dipole-incompatible part. 2) In spatially continuous space, the streaking-free susceptibility solution is obtained from the dipole-compatible field data only, and the dipole-incompatible data leads to artifacts defined by a wave propagator with z as time, specifically, streaking artifacts from granular noise and shadow artifacts from white matter noise error. Although it is not known how to filter out such dipole-incompatible data, its artifacts can be suppressed in regularization-based Bayesian methods such as MEDI, which can efficiently penalize streaking artifacts. k -space-truncation-based methods that generate additional dipole-incompatible data near the zero cone amplify streaking artifacts.

Imaging Cerebral Arteries and Veins using Susceptibility Weighted Imaging with Ferumoxytol

Saifeng Liu¹, Jean-Christophe Brisset², Sagar Buch¹, Jing Jiang³, E. Mark Haacke^{1,3}, and Yulin Ge²

¹The MRI Institute for Biomedical Research, Waterloo, ON, Canada, ²Radiology/Center for Biomedical Imaging, New York University School of Medicine, NY, United States, ³Department of Radiology, Wayne State University, MI, United States

Susceptibility weighted imaging (SWI) has been widely used to image cerebral venous structures and in vivo iron content. However, it has not been used to image arteries, because of the lack of susceptibility contrast between arteries and the surrounding tissue. In this study, the susceptibility of the arterial blood was purposely modified to make it visible with SWI, by using the USPIO (ultra-small superparamagnetic iron oxide) agent Ferumoxytol. The purpose of this study is to determine the relationship between Ferumoxytol concentration and susceptibility using phantom and simulation studies, and compare these findings with those obtained from in vivo data.

Coherence Enhancement in QSM via Anisotropic Weighting in Morphology-Enabled Dipole Inversion

Youngwook Kee¹, Pascal Spincemaille¹, Junghun Cho^{1,2}, and Yi Wang^{1,2}

¹Weill Cornell Medical College, New York, NY, United States, ²Cornell University, Ithaca, NY, United States

The current regularization in morphology-enabled dipole inversion (MEDI) does not take into account orientation information in morphology between QSM and its corresponding magnitude image. In this abstract, we consider such orientation information to enhance structural coherence between the two images. In doing so, we achieve better image quality as well as higher RMSE (root mean square error) and HFEN (high frequency error norm) with respect to COSMOS and $\chi_{(3)}$.

Computer 109

Improved Morphology Enabled Dipole Inversion for Quantitative Susceptibility Mapping by Using Prior Information

Yihao Guo¹, Li Guo¹, Yingjie Mei^{1,2}, Jijing Guan¹, and Yanqiu Feng¹

¹Guangdong Provincial Key Laboratory of Medical Image Processing, School of Biomedical Engineering, Southern Medical University, Guangzhou, People's Republic of China, ²Philips Healthcare, Guangzhou, China.

Morphology enabled dipole inversion (MEDI) has been proposed to reconstruct QSM without obvious streaking artifacts at the smooth regions of susceptibility map. However, reconstruction errors or streaking artifacts near edges are not addressed by MEDI. In this work, we aim to improve MEDI by constraining the edges of susceptibility map with prior information.

Computer 110

Automatic venous vessel segmentation in high field, multi-echo SWI using Random Forests

Albert Rechberger^{1,2}, Barbara Dymerska², Karin Poljanc³, Georg Langs¹, and Simon Daniel Robinson²

¹Computational Imaging Research Lab, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria, ²High Field MR Centre, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria, ³Atominstut, TU Wien, Vienna, Austria

A method for automatic venous vessel segmentation is presented that uses a Random Forest classifier supplied with a number of appearance and shape features computed separately from magnitude images, phase images and QSMS of a multi-echo T2*-weighted GE scan. The importance of each feature, and thus each echo, is investigated. The approach was tested on whole-brain 7T scans of four subjects, two of which were manually annotated, and was effective in segmenting both internal and surface veins.

Resolution and Coverage for Accurate Susceptibility Maps: Comparing Brain Images with Simulations

Anita Karsa¹, Shonit Punwani², and Karin Shmueli¹

¹Department of Medical Physics and Biomedical Engineering, University College London, London, United Kingdom, ²Centre for Medical Imaging, University College London, London, United Kingdom

Magnetic Susceptibility Mapping is moving closer to clinical application. To reduce scan time, clinical images are often acquired with reduced resolution and coverage in the through-slice dimension. The effect of these factors has been studied using only balloon phantoms and downsampled brain images. Here, we used MR images acquired at low resolution or low coverage and compared these with images simulated in volunteers and a realistic numerical phantom. Simulated susceptibility maps were very similar to maps from acquired images. Our results show that low resolution and very low coverage both lead to loss of contrast and errors in susceptibility maps.

Computer 112

Phase processing for quantitative susceptibility mapping of regions with large susceptibility and lack of signal
Véronique Fortier^{1,2} and Ives R. Levesque^{1,2,3}

¹Medical Physics Unit, McGill University, Montréal, QC, Canada, ²Biomedical Engineering, McGill University, Montréal, QC, Canada, ³Research Institute of the McGill University Health Centre, Montréal, QC, Canada

Phase unwrapping and background removal algorithms directly impact quantitative susceptibility maps. Phase processing techniques have been thoroughly studied for brain applications, but accuracy in the presence of large susceptibility and negligible signal, such as bone and air regions, is unknown. The performance of phase processing algorithms was evaluated quantitatively in simulations with a numerical head phantom and qualitatively *in vivo* in three head datasets. In these experiments, Laplacian-based unwrapping performed poorly. Accurate background removal remains an open question. Results suggest that Quality-Guided unwrapping should be preferred with background removal using Projection onto Dipole Fields.

3679

Computer 113

Evaluation of air/bone segmentation using susceptibility-based imaging methods

Emma Dixon¹, David L Thomas², Anna Barnes³, and Karin Shmueli¹

¹Medical Physics and Biomedical Engineering, University College London, London, United Kingdom, ²Leonard Wolfson Experimental Neurology Centre, University College London, Institute of Neurology, United Kingdom, ³Institute of Nuclear Medicine, UCLH-NHS Foundation Trust, United Kingdom

Due to the difference in magnetic susceptibility of air, teeth and bone, magnetic susceptibility mapping has the potential to enable segmentation of these regions despite the absence of direct MRI signal. Several methods have been described which attempt to calculate the magnetic susceptibility within air and bone. Two datasets are used to test the ability of these methods to distinguish between air and bone. The performance of all methods varied between datasets and depended strongly on the parameters selected. None of the methods performed consistently better across groups, but all showed potential to improve air/bone segmentation using susceptibility mapping.

A comprehensive assessment of methods for combining phase data from array radio-frequency coils at 7 T

Simon Daniel Robinson¹, Korbinian Eckstein¹, José Rebelo Ferreira Marques², Berkin Bilgic³, Siegfried Trattnig¹, and Ferdinand Schweser^{4,5}

¹Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria, ²Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen, Netherlands, ³Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, MA, United States, ⁴Department of Neurology, University at Buffalo, NY, United States, ⁵MRI Clinical and Translational Research Center, University at Buffalo, NY, United States

Methods for combining phase data from array RF coils are quantitatively compared at 7 T. Of the reference-free approaches (which all leave arbitrary contributions to the total phase), the Virtual Reference Coil method yielded the best phase matching. The reference-free method COMPOSER removed non-B₀-related phase but requires an artifact-free short echo-time reference measurement. Of the multi-echo methods, SVD, HIP and ASPIRE all had uniform phase matching. ASPIRE has higher CNR for a narrow range of echo times, but requires TE₂=2 x TE₁. The data and assessment scripts used in this study will be made publicly available.

3681

Computer 115

Evaluation of Accuracy of MR phase and R₂* for susceptibility quantification

Yongquan Ye¹, Li Yang², Mengsu Zeng², Shengxiang Rao², Ying Ding², Jinguang Zong³, and Xixi Wen³

¹United Imaging of Healthcare America, Houston, TX, United States, ²Department of Radiology, Shanghai Institute of Medical Imaging, Zhongshan Hospital, Fudan University, Shanghai, People's Republic of China, ³Shanghai United Imaging of Healthcare, Shanghai, People's Republic of China

Computer simulation was performed to evaluate the relationship between a voxel's bulk susceptibility and its R₂* or phase behavior. A virtual voxel with multi-dipole model was created, and the effects of dipole properties on the accuracy and consistency of R₂* and phase on reflecting the voxel's bulk susceptibility was investigated. Linearity is only observed at low bulk susceptibility regime, and phase is much more robust against various susceptibility dipole properties than R₂*.

3682

Computer 116

Texture analyses of quantitative susceptibility maps to differentiate patients with Parkinson's disease from healthy controls

Gaiying Li¹, Guoqiang Zhai¹, Xinxin Zhao¹, Hedi An², Tian Liu³, Yi Wang^{1,3}, Dongya Huang², and Jianqi Li¹

¹Shanghai Key Laboratory of Magnetic Resonance and Department of Physics, East China Normal University, Shanghai, People's Republic of China, ²Department of Neurology, East Hospital, Tongji University School of Medicine, Shanghai, People's Republic of China, ³Department of Radiology, Weill Medical College of Cornell University, NY, United States

QSM provides excellent contrast of iron-rich deep nuclei to quantify iron in the brains. Clinicians are interested in using QSM to diagnose patients with Parkinson's disease (PD). Texture analyses of QSM images in substantia nigra (SN) was performed to differentiate PD from healthy controls (HC). Most of the texture parameters were significantly different between PD and HC. The second-order textures were more efficient in differentiating PD from HC than did the first-order, which suggests that the second-order texture parameters are more suitable and sensitive for the diagnosis of PD.

Computer 117

Ultrashort Echo Time Quantitative Susceptibility Mapping (UTE-QSM): Limitations in Quantifying High Iron Concentration
Xing Lu^{1,2}, Alexey Dimov³, Qun He¹, Yajun Ma¹, Yi Wang³, Eric Y Chang^{1,4}, and Jiang Du¹

¹Department of Radiology, University of California, San Diego, CA, United States, ²Institute of Electrical Engineering, Chinese Academy of Science, Beijing, People's Republic of China, ³Department of Radiology, Weill Cornell Medical College, New York, NY, United States, ⁴Radiology Service, VA San Diego Healthcare System, San Diego, CA, United States

Iron overload can affect not only the central nervous system, but the liver, pancreas, myocardium, endocrine glands, and musculoskeletal structures. A reliable quantitative method to detect and measure high concentration iron in vivo would be of great clinical utility. Ultrashort echo time (UTE) sequences have echo times (TE) 100-1000 times shorter than clinical sequences, and may detect signal from high iron concentration. In this study, we aimed to evaluate the capability of UTE-QSM sequence in quantifying high iron concentration with an Iron phantom study and the results show that UTE-QSM techniques can quantify high iron concentration up to 22 mM or higher.

3684

Computer 118

Comparison of Quantitative Susceptibility Mapping algorithms based on numerical and in vivo 3T data
Hanneke Geut¹, Louise van der Weerd¹, and Itamar Ronen²

¹Radiology, Leiden University Medical Center, Leiden, Netherlands, ²C.J. Gorter Center for High Field MRI Research, Leiden University Medical Center, Leiden, Netherlands

This study compares the currently publicly available algorithms for quantitative susceptibility mapping, including different phase unwrapping, background field removal and dipole inversion methods. Numerical and human in vivo brain MRI data are used for a qualitative and quantitative assessment of the various methods. In 3T in vivo MRI data, phase unwrapping with combined spatial and temporal fitting and background field removal using V-SHARP results in the least artifacts. MEDI and iLSQR are currently the most accurate dipole inversion algorithms, with a significantly shorter processing time for the iLSQR method.

Computer 119

Biological underpinnings of different MR contrasts in the human midbrain using quantitative structural MR imaging at 9.4T: Validation with 14T ex-vivo measurements and PLI

Joana Loureiro¹, Gisela Hagberg, Elisa Tuzzi, Rolf Pohmann, Zora Schickardt, Marc Himmelbach, Thomas Ethofer, Matthias Valverde, Wolfgang Grodd, and Klaus Scheffler

¹High field MR, Max Planck Institute for Biological Cybernetics, Tuebingen, Germany

In this study we use relaxometry and susceptibility mapping to obtain enhanced contrast in the midbrain, in particular in the superior colliculus (SC). High resolution GRE images were obtained in 11 subjects at 9.4T. We calculated CNR values for each contrast for three midbrain regions (superior colliculus, red nucleus and aqueductal gray). were obtained across 11 subjects in individual and MNI space. These measurement were validated with ex-vivo measurements in the 9.4T, 14.1T and PLI imaging.

Investigation of Brain Tissue Fixation on Iron Concentration, Magnetic Susceptibility and Effective Transverse Relaxation Rate

Andreas Deistung^{1,2}, Verena Endmayr³, Simon Hametner³, Max Prihoda^{4,5}, Xiang Feng¹, Hans Lassmann³, Jürgen Rainer Reichenbach¹, Simon Daniel Robinson⁶, Evelin Haimburger⁴, Christian Menard⁷, Thomas Haider⁸, Hannes Traxler⁹, Siegfried Trattnig⁶, and Günther Grabner^{4,5,6}

¹Medical Physics Group, Institute for Diagnostic and Interventional Radiology, Jena University Hospital – Friedrich Schiller-University, Jena, Germany, ²Section of Experimental Neurology, Department of Neurology, Essen University Hospital, Essen, Germany, ³Center for Brain Research, Medical University of Vienna, Vienna, Austria, ⁴Department of Radiologic Technology, Carinthia University of Applied Sciences, Klagenfurt, Austria, ⁵Institute for Applied Research on Ageing, Carinthia University of Applied Sciences, Klagenfurt, Austria, ⁶High Field Magnetic Resonance Centre, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria, ⁷Department of Medical Engineering, Carinthia University of Applied Sciences, Klagenfurt, Austria, ⁸University Clinic for Trauma Surgery, Medical University of Vienna, Vienna, Austria, ⁹Center of Anatomy and Cell Biology, Medical University of Vienna, Vienna, Austria

We investigated the effect of brain tissue fixation on iron concentration and on quantitative maps of the magnetic susceptibility and effective transverse relaxation rate ($R2^*$). Both $R2^*$ and susceptibility distributions of unfixed and fixed tissue were found to be similar, indicating similar underlying proportions of iron across tissues. Quantitatively, however, severe decreases of iron concentration of 25% in putamen and about 15% in white matter were measured after tissue fixation. The iron concentration change due to tissue fixation was captured by $R2^*$ and susceptibility which needs to be considered when directly comparing experiments performed with unfixed and fixed brain tissue.

Simultaneous multislice acquisition without trajectory modification for hyperpolarized ¹³C experiments

Angus Z. Lau^{1,2}, Albert P. Chen³, Justin Y.C. Lau^{1,2}, and Charles H. Cunningham^{1,2}

¹Physical Sciences, Sunnybrook Research Institute, Toronto, ON, Canada, ²Medical Biophysics, University of Toronto, Toronto, ON, Canada, ³GE Healthcare, Toronto, ON, Canada

Recently we proposed using simultaneous multislice (SMS) acceleration to improve spatial coverage in the hyperpolarized ¹³C experiment, and demonstrated that controlled aliasing improves conditioning of the inverse problem. For single-shot experiments this requires gradient modulation along z, which can be sensitive to gradient imperfections. Here, we show that inherent coil sensitivity variations can be sufficient for SMS acceleration in hyperpolarized ¹³C experiments, without additional readout gradient modification. Two-fold acceleration with a 8 cm slice gap can be obtained with less than 20% SNR loss. We anticipate that this strategy will enable multiple organ ¹³C imaging of in vivo metabolism.

Slice Selective Adiabatic Refocusing Pulses for High Field, Pre-Clinical Hyperpolarized C-13 Imaging

Xucheng Zhu¹, Jeremy W Gordon², and Peder EZ Larson^{1,2}

¹Bioengineering, UCSF, Albany, CA, United States, ²Radiology & Biomedical Imaging, University of California - San Francisco, CA, United States

Due to limited transmit coil volume, refocusing pulses spoil magnetization located around the edge of the coil even with adiabatic pulses. This is a major problem for hyperpolarized ¹³C MRI, as this can destroy precious magnetization. To overcome this drawback, we propose to use a high bandwidth slice-selective adiabatic pulse to replace the original non-selective pulse. We designed and optimized the pulse via simulation. Then the slice-selective double spin echo sequence was tested on both phantom and in vivo studies.

Improved Off-Resonance Robustness for Spectral-Spatial Excitation and Echo-Planar Imaging of Hyperpolarized [1-¹³C]Pyruvate and Metabolites

Justin YC Lau^{1,2}, Benjamin J Geraghty^{1,2}, Yiping Gu¹, Albert P Chen³, and Charles H Cunningham^{1,2}

¹Physical Sciences, Sunnybrook Research Institute, Toronto, ON, Canada, ²Medical Biophysics, University of Toronto, Toronto, ON, Canada, ³GE Healthcare, Toronto, ON, Canada

An interleaved multi-echo imaging sequence is proposed to improve off-resonance robustness for spectral-spatial excitation and echo-planar imaging of hyperpolarized [1-¹³C]pyruvate. A non-iterative pointwise k-space signal decomposition approach for removing pyruvate hydrate contamination from lactate images is presented. Performance of the sequence and reconstruction pipeline was evaluated using an ethylene glycol phantom and a catalyzing enzyme system. Minimal signal loss and successful removal of pyruvate hydrate contamination were demonstrated in vivo for realistic cases of off-resonance.

3D Hyperpolarized C-13 EPI with Calibrationless Parallel Imaging

Jeremy W Gordon¹, Yesu Feng¹, Peter Shin¹, Daniel B Vigneron¹, and Peder EZ Larson¹

¹Radiology & Biomedical Imaging, UCSF, San Francisco, CA, United States

With the translation of hyperpolarized ¹³C to the clinic, imaging approaches will require large volumetric FOVs to support clinical applications. Parallel imaging techniques will be crucial to increasing volumetric scan coverage while minimizing RF requirements and temporal resolution. Calibrationless parallel imaging approaches are well-suited for this application because they eliminate the need to acquire coil profile maps or auto-calibration data. In this work, we explored the application of calibrationless parallel imaging (SAKE) and corresponding sampling strategies to accelerate and undersample hyperpolarized ¹³C data using 3D blipped EPI acquisitions and multichannel receive coils.

Fast and robust symmetric echo planar spectroscopic imaging sequence for hyperpolarized ¹³C in a clinical system is presented. The sequence employs a reconstruction algorithm that re-grids the sampled data in the spatio-temporal frequency space to compensate for the chemical shift artifacts and achieve an improved reconstruction within a limited bandwidth. The sequence was tested on a clinical 3 T whole body scanner using dedicated ¹³C coils and was compared with the conventional chemical shift imaging. Good tradeoff between speed, efficiency and SNR was achieved and the reconstruction was superior compared to the commonly used FFT reconstruction.

Computer 6

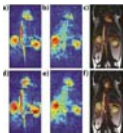

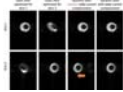

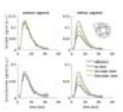

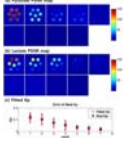

Multi-echo balanced steady state imaging of hyperpolarized [1-¹³C]-pyruvate at 9.4T

Christian Østergaard Mariager¹, Mette Ji Riis-Vestergaard¹, Haiyun Qi¹, Steffen Ringgaard¹, and Christoffer Laustsen¹

¹Department of Clinical Medicine, The MR Research Centre, Aarhus University Hospital, Aarhus N, Denmark

Hyperpolarized (HP) [1-¹³C]-pyruvate imaging has gained increasing attention, as its ability to monitor metabolic changes in real-time is expected to have a great clinical impact. In this work we investigate the use of a fast multi-echo balanced steady state free precession (BSSFP) sequence to acquire spectroscopic images at 9.4T. We show that this technique, in combination with the iterative Dixon type reconstruction technique (IDEAL), yields dynamic high resolution spectroscopic maps in a ¹H phantom as well as for preliminary in vivo HP [1-¹³C]-pyruvate experiments in rat kidneys.

- 3693 **Computer 7** [High Spatiotemporal Resolution bSSFP Imaging of Hyperpolarized \$^{13}\text{C}\$ Lactate and Pyruvate using Spectral Suppression of Alanine and Pyruvate-hydrate at 3T](#)

 Eugene Milshteyn^{1,2}, Cornelius von Morze¹, Jeremy W. Gordon¹, Zihan Zhu^{1,2}, Peder E. Z. Larson^{1,2}, and Daniel B. Vigneron^{1,2}
¹Radiology and Biomedical Imaging, UCSF, San Francisco, CA, United States, ²UC Berkeley-UCSF Graduate Program in Bioengineering, UCSF and University of California, Berkeley, San Francisco, CA, United States
- The bSSFP sequence provides high spatial and temporal resolution capabilities, but has a difficult to manage frequency response at 3T with regards to hyperpolarized [^{13}C]pyruvate and its products. The purpose of this project was to integrate a spectral suppression pulse, designed to suppress alanine and pyruvate-hydrate, with the bSSFP sequence to image [^{13}C]pyruvate and its conversion to [^{13}C]lactate. The results showed no significant effect on quantitative analysis of lactate-to-pyruvate ratios or k_{p} after suppression of alanine and pyruvate-hydrate. Subsequently, dynamic imaging of [^{13}C]pyruvate and [^{13}C]lactate at high in-plane spatial resolution was achieved with the bSSFP sequence.

 Tom H. Peeters¹, Thiele Kobus¹, Andor Veltien¹, Arend Heerschap¹, and Tom W.J. Scheenen¹
¹Radiology and Nuclear Medicine, Radboud university medical center, Nijmegen, Netherlands
- The delivery of targeted metabolic compounds can be hindered by a natural barrier in the brain. Nowadays, focused ultrasound techniques allow temporarily opening of this blood-brain barrier (BBB). Here we investigated the feasibility to combine this technique with dynamic imaging of hyperpolarized (HP) pyruvate. After opening the BBB in a focal spot, we acquired *in vivo* HP pyruvate images of the mouse brain using a dynamic gradient-echo imaging acquisition scheme at 7T. This approach eventually allows investigations with hyperpolarized compounds in the brain that are usually hindered by the BBB or suffer from a too slow uptake for DNP-imaging.

Repeatability of quantitative hyperpolarized ¹³C MRSI measures of renal metabolism: impact of flow-sensitive gradients

Erin B Adamson¹, Kai D Ludwig¹, Benjamin L Cox^{1,2,3}, and Sean B Fain^{1,4,5}

¹Medical Physics, University of Wisconsin-Madison, Madison, WI, United States, ²Morgridge Institute for Research, Madison, WI, United States, ³Laboratory for Optical and Computational Instrumentation, University of Wisconsin-Madison, Madison, WI, United States, ⁴Radiology, University of Wisconsin-Madison, Madison, WI, United States, ⁵Biomedical Engineering, University of Wisconsin-Madison, Madison, WI, United States

Real-time quantification of *in vivo* metabolism with hyperpolarized ¹³C magnetic resonance spectroscopic imaging (MRSI) is currently limited by partial volume effects from intense vascular signal. Flow-sensitive, bipolar gradients are an attractive option for suppressing vascular signal due to their minimal influence on static spins. This work looks at the impact of incorporating bipolar gradients on the quantification and repeatability of hyperpolarized ¹³C MRSI metabolic measures of lactate-to-pyruvate area-under-the-curve ratios (AUC_{ratio}). The results suggest that incorporating bipolar gradients mitigates vascular partial voluming, increasing measured AUC_{ratio}, while reducing measurement repeatability, indicated by the larger repeatability coefficients.

Cost-efficient hyperpolarization of long-lived nuclear spin states on carbon-13 spin pairs

Thomas Theis¹, Zijian Zhou¹, Jin Yu¹, Johannes Colell¹, and Warren Warren^{1,2}

¹Department of Chemistry, Duke University, Durham, NC, United States, ²Departments of Physics, Radiology and BME, Duke University, Durham, NC, United States

Current hyperpolarization methods used in preclinical research are limited by high cost (>\$2M) and short hyperpolarization lifetimes (<1 min). Here we demonstrate hyperpolarization of long-lived states with inexpensive equipment. Specifically, we use parahydrogen which is simple to produce (<\$10k in equipment costs) and transfer its singlet hyperpolarization by non-reactive polarization transfer to long-lived singlet states on ¹³C spin pairs in molecular substrates. We detail polarization transfer mechanisms and obtain hyperpolarization lifetimes in excess of two minutes. Moving forward, we expect to achieve hyperpolarization lifetimes of hours as has been demonstrated on thermally polarized ¹³C spin pairs.

Hyperpolarized MRI is a powerful approach to non-invasive biomolecular imaging because of high sensitivity and excellent molecular specificity. However, current methods are limited by high cost (>\$5M) and short hyperpolarized signal lifetimes (<1 min). We overcome both limitations by low field (6.5 mT) imaging of molecules polarized by non-reactive transfer of spin order from parahydrogen. Both, parahydrogen polarizers and low-field MRI hardware are simple technologies affordable on a modest budget (<\$200k). At low fields, we establish hyperpolarization decay time constants of above 20 min, greatly exceeding current markers. This suggests highly sensitive biomolecular MR imaging could be done at the cost of an X-Ray.

Development of nanometer size silicon nanoparticles for hyperpolarized MRI

Grzegorz Kwiatkowski¹, Jonas Steinhauser¹, Patrick Wespi¹, Matthias Ernst², and Sebastian Kozerke¹

¹Institute for Biomedical Engineering, ETH Zurich, Zurich, Switzerland, ²Physical Chemistry, ETH Zurich, Zurich, Switzerland

Hyperpolarized silicon particles have been shown to exhibit enormously long T_1 relaxation at room temperature, making them favourable as novel imaging MR probes. To date, only large particles (average particle size (APS)=2.2 μm) could be efficiently polarized, restricting their in-vivo applicability.

The objective of the present work was to develop nanometre size hyperpolarized silicon-29 particles (APS= 55+/-12 nm) with superior MR properties. A maximum achievable polarization of 12.6% is reported with relaxation time of 42 min at room temperature. Applications of imaging of both solid and colloidal dispersion of silicon particles are demonstrated.

Hyperpolarized silicon nano- and microparticles hold great promise as targeted molecular imaging agents due to their overall biocompatibility and long-lasting enhanced MRI signals. We performed dynamic nuclear polarization on silicon microparticles that were functionalized with an antibody that targets Mucin overexpression in colorectal cancer. Conjugation of the antibody to the particle surface did not affect the ²⁹Si hyperpolarization characteristics, and *in vivo* imaging was attained 20 minutes after particle injection into a colorectal cancer mouse model. The goal is to develop these targeted particles as a platform technology that will allow non-invasive screening of colorectal cancer using ²⁹Si MRI.

¹³C-MR Hyperpolarization of Lactate using ParaHydrogen and metabolic transformation in vitro.

Eleonora Cavallari¹, Carla Carrera¹, Silvio Aime¹, and Francesca Reineri¹

¹Department of Molecular Biotechnology and Health Sciences, University of Torino, Torino, Italy

Hyperpolarization (HP) of the ¹³C magnetic resonance signal of [1-¹³C]-lactate has been obtained using the ParaHydrogen Induced Polarization by means of Side Arm Hydrogenation (PHIP-SAH). Different ester derivatives of lactate have been tested in order to optimize the hydrogenation kinetics and the polarization level on the product. The metabolic transformation of hyperpolarized [1-¹³C]-lactate into pyruvate has been observed in vitro. The bio-compatibility of the aqueous solution and the good polarization level (7.9±0.4%) make the hyperpolarized metabolite thus obtained a good candidate for metabolic imaging studies.

3708

Computer 22

Combined Hyperpolarized Pyruvate and Lactate as a Proxy for Hyperpolarized Urea to Measure Tissue Perfusion

Christopher M Walker¹, Keith A Michel¹, Rafal J Zielinski², Waldemar Priebe², Dawid Schellingerhout³, and James A Bankson¹

¹Department of Imaging Physics, UT MD Anderson Cancer Center, Houston, TX, United States, ²Department of Experimental Therapeutics, UT MD Anderson Cancer Center, Houston, TX, United States, ³Department of Diagnostic Radiology, UT MD Anderson Cancer Center, Houston, TX, United States

Hyperpolarized pyruvate can be used to noninvasively probe metabolism in vivo. However, quantitative measurement of metabolic processes is frequently complicated by tissue perfusion. Metabolic inert compounds such as hyperpolarized urea have been used to measure tissue perfusion. This work shows a strong correlation between hyperpolarized urea signal and the sum of hyperpolarized pyruvate and lactate signal, suggesting that the combination of pyruvate and lactate signals can be used to estimate tissue perfusion.

Direct Relaxation Measurement from Clinical Sequences

Kelly C McPhee¹ and Alan H Wilman²

¹Physics, University of Alberta, Edmonton, AB, Canada, ²Biomedical Engineering, University of Alberta, Edmonton, AB, Canada

Through exact sequence response modeling using the Bloch equations, we propose direct extraction of quantitative T1 and T2 relaxation maps from standard clinical MRI sequences. This approach eliminates the need for excess specialized and complex sequences by measuring relaxation directly from clinical sequences. We demonstrate this method to determine T2 and T1 using a standard brain protocol of fast spin echo images weighted by proton-density, T2 and FLAIR at 3 T. Our approach opens the door to wider use of quantitative MRI.

3713

Computer 27

Whole Body Rapid T2 Quantification using Dual Echo Fast Spin Echo

Kelly C McPhee¹, Ashmita De², and Alan H Wilman²

¹Physics, University of Alberta, Edmonton, AB, Canada, ²Biomedical Engineering, University of Alberta, Edmonton, AB, Canada

We examine RF field variation on a modern 3T and illustrate T2 quantification using only PD and T2w fast spin echo images and a rapid flip angle map in the abdomen, spine, head, neck, and leg. Across the whole body at 3T or higher fields, RF field variation yields a wide variation in flip angles, requiring direct sequence modelling to achieve accurate T2.

3714

Computer 28

SNR Efficiency in Multi-Parameter Mapping (PD, T1 & T2*) at 3T: Comparison of MP2RAGE and VFA-FLASH

Jean-David Jutras¹, Keith Wachowicz^{1,2}, Guillaume Gilbert³, and Nicola De Zanche^{1,2}

¹Oncology, University of Alberta, Edmonton, AB, Canada, ²Medical Physics, Cross Cancer Institute, Edmonton, AB, Canada, ³MR Clinical Science, Philips Healthcare Canada, Markham, ON, Canada

Quantitative parametric mapping is becoming increasingly promising for improving the diagnostic quality and reproducibility of structural brain MR images. The variable flip angle technique with FLASH (VFA-FLASH) is a popular technique for mapping the proton-density, T1 and T2*. Recently, the MP2RAGE pulse sequence was developed to map T1 with robustness to RF inhomogeneity. If a multi-echo (bipolar) MP2RAGE is employed, proton-density and T2* can also be mapped simultaneously. In this study we compare the SNR efficiency and accuracy of VFA-FLASH and MP2RAGE for multi-parameter mapping at 3T. Both methods yield comparable T1-to-noise ratios, but VFA-FLASH is superior for PD and T2* mapping.

3715

Computer 29

Correction of off-resonance for T1 and T2 mapping using phase-cycled inversion-recovery balanced steady state free precession

Eric R. Muir¹ and Shengwen Deng^{2,3}

¹Research Imaging Institute and Ophthalmology, University of Texas Health Science Center, San Antonio, TX, United States, ²Research Imaging Institute, University of Texas Health Science Center, San Antonio, TX, United States, ³Biomedical Engineering, University of Texas at San Antonio, San Antonio, United States

Fast measurement of T₁ and T₂ can be made using inversion-recovery Look-Locker (LL) bSSFP methods. However, the LL-bSSFP signal is dependent on the off-resonance frequency which can affect calculated T₁ and T₂. In this study we develop and test methods to correct for effects of off-resonance on T₁ and T₂ calculation using multiple phase-cycled LL-bSSFP. The phase-cycled LL-bSSFP data could be combined with a maximum-T₁* projection method to improve T₁ and T₂ accuracy in the case of off-resonance.

Motion Corrected T₁ Mapping of the Pediatric Human Brain

Steven R Kecskemeti¹ and Andrew Alexander^{1,2,3}

¹Waisman Center, University of Wisconsin, Madison, WI, United States, ²Psychiatry, ³Medical Physics, University of Wisconsin, Madison, WI, United States

A method to retrospectively correct both in- and through-plane motions that occur during the acquisition of inversion recovery images is developed and used for motion-corrected T₁-mapping of the pediatric human brain. Both intra- and inter-scan motions are corrected.

3718

Computer 32

Fast T₁ mapping with temperature correction via DWI thermometry, and its application to vitreous oxygen measurement

Shengwen Deng¹, Eric Muir², Wei Zhou³, and Timothy Q. Duong²

¹University of Texas Health Science Center at San Antonio, San Antonio, TX, United States, ²University of Texas Health Science Center at San Antonio, ³Radiology, Mayo Clinic

T₁ mapping is showing great potential for mapping oxygen in human organs such as eyes and lungs. And yet, accuracy of oxygen using fast T₁ imaging methods is of great concern especially in tissue with radical temperature changes. In the current study we improve fast T₁ mapping with temperature correction and explore its potential in mapping oxygen in eyes. With combination of inversion-recovery Look-Locker bSSFP and diffusion weighted thermometry, we calibrate the temperature dependence of ADC and T₁, and use it to adjust the R1 for measuring partial pressure of oxygen (pO₂). Fast T₁ mapping could be a reliable way to pO₂ that well agrees with invasive oxygen-sensitive optic fibers.

3719

Computer 33

A rapid, whole-brain look-locker method for T₁ mapping using inversion recovery EPIK

N. Jon Shah^{1,2} and Seong Dae Yun¹

¹Institute of Neuroscience and Medicine, Medical Imaging Physics (INM-4), Forschungszentrum Juelich, Juelich, Germany, ²Faculty of Medicine, Department of Neurology, JARA, RWTH Aachen University, Aachen, Germany

Quantitative measurement of the T₁ relaxation time is of great importance for the clinical diagnosis or optimisation of image contrast. Numerous Look-Locker methods have been proposed for T₁ mapping. One of them demonstrated by the community is TAPIR which has been shown to be fast and robust. However, TAPIR still demands substantial acquisition time for whole-brain coverage. This work aims to develop a fast Look-Locker method with whole-brain coverage on a basis of EPIK. It was shown that the proposed method acquired whole-brain T₁ data (2.1 mm² resolution × 50 slices × 30 time-points) within 3.5 minutes.

Rapid high-resolution 3D T₁ mapping using a highly accelerated radial inversion-recovery FLASH technique

Zhitao Li¹, Ali Bilgin^{2,3}, Diego R. Martin⁴, and Maria I. Altbach⁴

¹Electrical and Computer Engineering, The University of Arizona, Tucson, AZ, United States, ²Electrical and Computer Engineering, The University of Arizona, ³Biomedical Engineering, The University of Arizona, ⁴Department of Medical Imaging, The University of Arizona

A golden angle radial IR-FLASH technique and a principle component based iterative algorithm are developed for high-resolution T₁ mapping using highly undersampled 3D radial data. The novel method yields T₁ maps of a 3D volume with high spatial and temporal resolution and can cover 144 slices within 5 minutes.

3721

Computer 35

Quantitative 3D T₁ mapping technique in rat brain using VFA-FLASH at 9.4T

Hedok Lee¹, Simon Sanggaard², Kristian Mortensen², Palle Koch², Maiken Nedergaard^{2,3}, and Helene Benveniste¹

¹Anesthesiology, Yale University, New Haven, CT, United States, ²Center for Basic and Translational Neuroscience, University of Copenhagen, Copenhagen, Denmark, ³Neurosurgery, University of Rochester, NY, United States

3D whole brain T1 mapping technique at 9.4T is studied because of a lack of methodological consideration in spite of its utility in pre-clinical paramagnetic and manganese contrast enhanced imaging studies. We report a simple and accurate 3D T1 mapping technique using variable flip angles spoiled gradient echo sequence with B1+ correction. Accuracy of the technique was validated using phantoms and a population averaged 3D rat T1 map was constructed.

3722

Computer 36

Model-Based Super-Resolution Reconstruction of T2 Maps

Tom Hilbert^{1,2,3}, Jose P Marques⁴, Jean-Philippe Thiran^{2,3}, Reto Meuli², Gunnar Krueger^{2,3,5}, and Tobias Kober^{1,2,3}

¹Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, Switzerland, ²Department of Radiology, University Hospital (CHUV), Lausanne, Switzerland, ³LTS5, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ⁴Donders Institute, Radboud University, Nijmegen, Netherlands, ⁵Siemens Medical Solutions USA, Inc., Boston, MA, United States

We propose an algorithm that can reconstruct 0.9mm³ isotropic T2 maps based on multiple 2D multi-echo spin-echo acquisitions that were highly undersampled. The data is reconstructed by combining a classical super-resolution approach with an iterative model-based reconstruction. Thereby, the reconstruction problem is split into multiple sub-problems to improve the convergence of the algorithm. Resulting T2 values within structures of the midbrain and the hippocampus from four healthy volunteers showed good reproducibility. This kind of high-resolution relaxometry may enable additional insight in pathologies of small brain structures and increased sensitivity to disease-induced changes.

Computer 37

A time domain signal equation for multi-echo spin-echo sequences with arbitrary excitation and refocusing angle and phase

Andreas Petrovic¹, Christoph Stefan Aigner¹, and Rudolf Stollberger¹

¹Institute of Medical Engineering, Graz University of Technology, Graz, Austria

T₂ quantification with multi-echo spin-echo sequences is often hampered by flip angle inhomogeneities and non-rectangular slice profiles. Here, we present a novel time domain signal equation for multi-echo spin-echo sequences with arbitrary excitation and refocusing flip angles and phases. To evaluate the equation simulations and phantom measurements were compared. Excellent agreement was found for the simulated and measured evolution of the transverse magnetization across the slice profile in a CP and a CPMG sequence. T₂ mapping using the proposed signal equation and the incorporation of scanner specific RF pulse shapes will greatly improve T₂ quantification accuracy.

3724

Computer 38

Assessing the Accuracy of T2 and B1+ Maps Estimated from Multi-echo Spin Echo MRI Sequences Using Extended Phase Graph Signal Predictions

Nuno Saraiva Santos^{1,2}, Rui Pedro A G Teixeira³, Joseph V Hajnal³, and Rita G Nunes^{1,2,3}

¹Institute for Systems and Robotics / Department of Bioengineering, Instituto Superior Técnico, Universidade de Lisboa, Lisbon, Portugal,

²Instituto de Biofísica e Engenharia Biomédica, Faculdade de Ciências, Universidade de Lisboa, Lisbon, Portugal, ³Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom

Interpretation of T2-weighted images still remains highly reliant on subjective clinical evaluation. Quantitative mapping using the gold standard approach (single spin-echo), although appealing, remains unfeasible in clinical practice. Multi-SE sequences have emerged as viable solutions allowing much shorter scan times at the expense of signal contamination by indirect echoes. A method based on the MR Fingerprinting concept has recently been proposed, estimating T2 and B1+ maps from pre-computed Echo Modulation Curves. This study evaluated the performance of this method performing Monte Carlo simulations followed by an *in vivo* acquisition. The method provided accurate T2 maps, despite highly biased B1+ estimates.

3725

High-resolution 3D T2 mapping of the Brain Using T2-prepared Cartesian Spiral Phyllotaxis FLASH and Compressed Sensing

Emilie Priscille Claire Mussard^{1,2,3}, Tom Hilbert^{1,2,3}, Christoph Forman⁴, Reto Meuli², Jean-Philippe Thiran³, and Tobias Kober^{1,2,3}

¹Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, Switzerland, ²Department of Radiology, University Hospital (CHUV), Lausanne, Switzerland, ³LTS5, École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland, ⁴HC DI MR PI TIO CARD,

Siemens Healthcare GmbH, Erlangen, Germany

Brain T2 relaxometry can provide sensitive biomarkers for pathological tissue alterations, especially inflammation. But their acquisition is often 2D-based and typically comes with long acquisition times. To improve through-slice resolution while keeping a clinically feasible scan time, we propose a centric T2-prepared variable-density Cartesian spiral phyllotaxis FLASH sequence combined with a compressed sensing reconstruction. Phantom experiments and a preliminary *in-vivo* scan show that T2 values can be reliably measured in 3D with high resolution. Parameter dependencies are evaluated and an initial protocol optimisation yields an acquisition time of 8.48min for a 1x1x1.2mm³ whole-brain acquisition.

¹Medicine, University of British Columbia, Vancouver, BC, Canada, ²Radiology, University of British Columbia, Vancouver, BC, Canada, ³Diagnostic Imaging Services, Interior Health, Kelowna, BC, Canada, ⁴Computer Science, Mathematics, Physics & Statistics, University of British Columbia, Kelowna, BC, Canada, ⁵Pediatrics, University of British Columbia, Vancouver, BC, Canada, ⁶GE Healthcare, Vancouver, BC, Canada, ⁷Pathology & Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada, ⁸International Collaboration on Repair Discoveries, University of British Columbia, Vancouver, BC, Canada, ⁹Physics and Astronomy, University of British Columbia, Vancouver, BC, Canada

T₂ relaxation using combined gradient and spin echo (GRASE) is a fast and robust approach for myelin water imaging in vivo. For long echo trains, when the noise floor is reached, the magnitude signal will converge towards a non-zero mean due to the Rician noise characteristics of the magnitude data. This can give rise to artificial long-T₂ components in analysis. In this study we employed temporal phase correction to multi-echo GRASE data and showed that for echo trains longer than 300ms, phase correction will effectively reduce artificial long-T₂ components, thus improving the ability to interpret the T₂ distribution.

Correction of fixation effects in post-mortem T₂ measurements using a kinetic tensor model

Feng Qi¹, Samuel A. Hurley¹, Menuka Pallegbage-Gamarallage², Olaf Ansorge², Martin R. Turner², Ricarda A. L. Menke², Sean Foxley¹, and Karla L. Miller¹

¹FMRIB Centre, University of Oxford, Oxford, United Kingdom, ²Department of Neurology, University of Oxford, Oxford, United Kingdom

MRI of fixed post-mortem tissue can be used to relate MR signals to histopathology. However, MR relaxation parameters are altered by the process of fixation. We propose a "kinetic tensor" model that simulates the influx of fixative into the brain using diffusion tensor data, and demonstrate a correction by fitting a fixative concentration map to quantitative T₂ measurements. Compared to correction methods based on distance-to-surface or isotropic diffusion, our approach captures an individual brain's morphology and microstructure, both of which influence fixation. T₂ maps corrected with the kinetic tensor model are more homogeneous than those with alternate corrections.

Computer 43

Ex vivo whole-blood T₂ versus HbO₂ calibration for T₂-prepared balanced steady-state free precession (bSSFP) at 1.5T

Ana E Rodriguez-Soto¹, Michael C Langham¹, Osheiza Abdulmalik², and Felix W Wehrli¹

¹Department of Radiology, University of Pennsylvania, Philadelphia, PA, United States, ²Division of Hematology, The Children's Hospital of Philadelphia, Philadelphia, PA, United States

The transverse relaxation rate (1/T₂) of blood water protons is governed by deoxyhemoglobin concentration, therefore providing a means to determine oxygen saturation (HbO₂) in vivo. However, besides CPMG inter-pulse interval of the T₂ preparation and field strength, whole-blood T₂ depends on sequence-specific parameters. Balanced SSFP allows for rapid image acquisition and higher in-plane resolution and thus provides an ideal readout for T₂-based oximetry. Here, we quantified T₂ of human blood at 1.5T for the entire range of HbO₂ saturation levels using T₂-prepared bSSFP sequence. The data show the expected linearity of 1/T₂ with (1-HbO₂)² with the y-intercept depending on hematocrit.

Inversion-recovery Ultrashort Echo Time Imaging with Bi-component T₂* Analysis of White Matter Signals in Native and Deuterated Ovine Brain Specimens

Shu-Juan Fan¹, Yajun Ma¹, Eric Y Chang^{1,2}, and Jiang Du¹

¹Dept. of Radiology, University of California, San Diego, San Diego, CA, United States, ²Radiology Service, VA San Diego Healthcare System, San Diego, CA, United States

Myelin protons have ultrashort-lived MR signals and are not accessible by clinical MRI. Such signals were probed herein using ultrashort echo time imaging (UTE) and inversion-recovery UTE (IR-UTE) with bi-component analysis in native and deuterated ovine brain specimens. UTE detected a fraction of ultrashort T₂ components (STC) of < 4% in native specimens, and up to ~54% in deuterated specimens. Choice of inversion time in IR-UTE significantly affected such bi-component signal decay behavior in native samples in heavily deuterated samples. These results support the application of UTE and IR-UTE in quantitative myelin imaging.

Magnetization Transfer MRI Noninvasively Detects Renal Fibrosis Swine Atherosclerotic Renal Artery Stenosis at 3.0 T

Kai Jiang¹, Christopher M. Ferguson¹, John R. Woollard¹, Roger C. Grimm², James D. Krier¹, Xiangyang Zhu¹, and Lilach O. Lerman¹

¹Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN, United States, ²Department of Radiology, Mayo Clinic, Rochester, MN, United States

In this study, we tested the capability of magnetization transfer (MT) imaging for measuring renal fibrosis in a swine model of atherosclerotic renal artery stenosis (ARAS) at 3.0 T. A collagen phantom study was performed to select appropriate offset frequencies of MT pulses for collagen detection. In an *in vivo* study, the MT ratio (MTR) and percent change in MTR between two offset frequencies were quantified, and both showed a good correlation with renal fibrosis measured *ex vivo* by Picro-Sirius red staining, supporting the use of MT to assess renal fibrosis in swine ARAS.

Modification of tumour hypoxia with Atovaquone measured by CEST MRI

Kevin J Ray¹, James Coates¹, Rathi Puliyadi¹, Thomas M Ashton¹, Paul Kinchesh¹, Sean Smart¹, Michael A Chappell², Geoff S Higgins¹, and Nicola R Sibson¹

¹Oxford Institute for Radiation Oncology, Department of Oncology, University of Oxford, Oxford, United Kingdom, ²Institute of Biomedical Engineering, Department of Engineering Science, University of Oxford, Oxford, United Kingdom

Tumours often have areas of hypoxia, which renders cancer cells resistant to many therapies. Recently the anti-malarial drug Atovaquone has been shown to modify the oxygen consumption rate of cancer cells, reducing tumour hypoxia. Non-invasive mapping of tumour hypoxia would be particularly useful for translation of these preclinical findings into a clinical environment. Here, we tested the hypothesis that CEST MRI could be used to visualise changes in tumour hypoxia.

Investigation into the origin of the APT MRI signal in ischemic stroke

Kevin J Ray¹, James R Larkin¹, Brad A Sutherland^{2,3}, George Harston², Andrew Baldwin⁴, Alastair M Buchan², Peter Jezzard⁵, James Kennedy², Michael A Chappell⁶, and Nicola R Sibson¹

¹Oxford Institute for Radiation Oncology, Department of Oncology, University of Oxford, Oxford, United Kingdom, ²Acute Stroke Programme and Acute Vascular Imaging Centre, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom, ³School of Medicine, Faculty of Health, University of Tasmania, Hobart, Australia, ⁴Physical and Theoretical Chemistry Laboratory, Department of Chemistry, University of Oxford, Oxford, United Kingdom, ⁵Oxford Centre for Functional MRI of the Brain, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom, ⁶Institute of Biomedical Engineering, Department of Engineering Science, University of Oxford, Oxford, United Kingdom

Studies employing CEST MRI to study ischemic stroke focus on the sensitivity of amide proton transfer (APT) MRI signals to tissue pH, assuming identical intracellular protein concentration as healthy tissue. This study shows that whilst cytoplasmic protein concentration remains stable in penumbral stroke regions, it decreases in the infarct core. By analysing APT MRI data with APTR*, which is specifically sensitive to amide proton exchange effects, we demonstrate that the APT signal change in infarct core is dominated by decreased protein concentration, whilst penumbral APT changes can be attributed to decreased tissue pH.

Reactive oxygen species (ROS) contribute to pathogenesis of many human diseases including Parkinson's and Alzheimer's diseases, cancer, and diabetes. There is a crucial need for using fully noninvasive imaging to further evaluate the role of ROS in pathogenesis and the potential treatment strategies. Our previous phantom studies demonstrated that ROS containing unpaired electrons can be detected with endogenous CEST and T₁ weighted contrasts. However, *in vivo* detection of ROS using MRI has not yet been demonstrated. This study therefore aimed to demonstrate the feasibility of *in vivo* ROS detection using endogenous MRI.

¹Molecular Imaging Research Center (MIRcen), Commissariat à l'Energie Atomique (CEA), Fontenay-aux-Roses, France, ²UMS27, INSERM, Fontenay-aux-Roses, France

GluCEST imaging has been proposed to image brain glutamate distribution with a better resolution than spectroscopic methods and has many potential applications for the study of neurodegenerative diseases. In this study, we pushed further the limits of gluCEST imaging by combining high magnetic field and high performance cryoprobe to acquire gluCEST images with the best resolution so far. Thanks to the organization of hippocampal cell layers and the high resolution, we acquired gluCEST data in regions mostly reflecting the neuronal compartment.

Assessment of hepatic glycogen metabolism *ex vivo* and *in vivo* in mice using chemical exchange saturation transfer MRI

Corin Miller¹, Jin Cao¹, Chunlian Zhang¹, Eduard Chekmenev², Bruce Damon², Alan Cherrington³, and John Gore²

¹Translational Imaging Biomarkers, Merck & Co., Inc, West Point, PA, United States, ²VUIIS, Vanderbilt University, Nashville, TN, United States, ³Vanderbilt Medical Center, Vanderbilt University, Nashville, TN, United States

Despite being integral to whole body glucose homeostasis, liver glycogen remains difficult to measure non-invasively. Recent works have demonstrated the feasibility of detecting liver glycogen using CEST MRI. In this presentation we present data that builds upon this observation and investigate whether CEST can be used to monitor glycogen synthesis and breakdown in mice in real time both ex vivo in a perfused liver system, and in vivo. Treatment with hyperglycemia or glucagon resulted in increases or decreases, respectively, in the CEST MTRAsym AUC over time. This demonstrates that CEST-based approaches can be used to non-invasively monitor glycogen metabolism.

GlucoCEST MRI and brain blood barrier permeability in the mouse brain

Maria Yanez Lopez¹, Nicoleta Baxan², Miriam Ries³, David Sharp¹, and Magdalena Sastre³

¹The Computational, Cognitive and Clinical Neuroimaging Laboratory, Division of Brain Sciences, Department of Medicine, Imperial College London, London, United Kingdom, ²The Imperial College Biological Imaging Centre, Department of Medicine, Imperial College London, London, United Kingdom, ³Division of Brain Sciences, Department of Medicine, Imperial College London, London, United Kingdom

The aim of the study is to examine the feasibility of using GlucoCEST to evaluate subtle BBB dysfunction in the mouse brain, by comparing it with conventional gadolinium DCE. DCE and GlucoCEST showed no significant differences between WT and 5XFAD mice (3 months). However, the degree of the response after injection was similar for DCE and GlucoCEST for all animals except one, indicating shared contributions to the signal and supporting the potential for biodegradable d-glucose as a cheap, low-risk alternative/complement to DCE MRI. More work is required to assess GlucoCEST sensitivity to low-level BBB dysfunction, such as in Alzheimer's disease.

Z-spectrum acquisition and interpretation in the presence of fat: influence of imaging parameters

Shu Zhang¹, Jochen Keupp², Ivan E Dimitrov^{3,4}, Robert E Lenkinski^{1,4}, and Elena Vinogradov^{1,4}

¹Department of Radiology, UT Southwestern Medical Center, Dallas, TX, United States, ²Philips Research, Hamburg, Germany, ³Philips Medical Systems, Gainesville, FL, United States, ⁴Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, TX, United States

CEST-MRI is increasingly evolving from brain to body applications. One of the known problems in body imaging is the presence of strong lipid signals. Their influence on the CEST signal is acknowledged but underexplored. The goal is to investigate the effects of lipids on the Z-spectrum taking TE into account. We performed simulations and verified the results in phantoms and *in vivo*. We demonstrate the mutual influence of fat fraction and TE on the Z-spectrum for gradient echo based sequences. This study provides a systematic understanding of lipid artifacts in CEST imaging and lays the foundations for their efficient removal.

Monitoring neoadjuvant chemotherapy in breast cancer patients using CEST and 31P-MRS at 7 tesla

Erwin Krikken¹, Vitaliy Khlebnikov¹, Moritz Zaiss², Wybe J.M. van der Kemp¹, Tijn A. van der Velden¹, Hanneke W.M. van Laarhoven³, Dennis W.J. Klomp¹, and Jannie P. Wijnen¹

¹Radiology, UMC Utrecht, Utrecht, Netherlands, ²Max Planck Institute for Biological Cybernetics, Tübingen, Germany, ³Oncology, Amsterdam Medical Center, Amsterdam, Netherlands

Treatment monitoring is of importance for breast cancer patients receiving systemic therapy. Metabolic imaging methods such as CEST and ³¹P-MRS may have potential to predict treatment efficacy in an early stage of the treatment. In this study we assessed the amide proton transfer (APT) signal and the pH change in breast cancer patients before and after the first cycle of neoadjuvant chemotherapy to explore the relation between APT and pH. We observed changes in both the APT signal and the pH between the two measurements. These changes may serve as biomarkers for predicting treatment response to NAC in an early stage.

Computer 86

Are MT and NOE (at -3.5 ppm) in z-spectroscopy coupled in the brain?

Nicolas Geades¹, Olivier E Mougín¹, Simon Shah¹, and Penny A Gowland¹

¹*Sir Peter Mansfield Imaging Center, University of Nottingham, Nottingham, United Kingdom*

The origin of the Nuclear Overhauser Enhancement (NOE) signal observed in the CEST spectrum of the brain is still under debate. The effect is detected upfield from water, in the frequency range of non-exchangeable aliphatic/olefinic protons, indicating that the transfer of magnetization is not occurring via proton or chemical exchange; furthermore the lineshape is relatively narrow, suggesting the signal is coming from mobile protons with T₂ of the order of 300μs. This study investigates the correlation between NOE and MT in the human brain at 7T, and shows the two effects are strongly coupled, across a wide age range.

3749

Computer 87

3D Quantitative CEST MRI of the human brain at 9.4T

Moritz Zaiss¹, Philipp Ehse¹, and Klaus Scheffler¹

¹*Magnetic Resonance Center, Max-Planck-Institute for biological cybernetics, Tuebingen, Germany*

Selective quantitative CEST MRI was shown to be feasible at 7T and for single-slice readout. In this study we extend qCEST MRI to a field strength of 9.4 T making use of the increase spectral resolution, and by employing a single-shot 3D CEST approach, more coverage of the human brain was realized.

3750

A longitudinal study of brain tumors in the course of radiotherapy using protein CEST MRI at 7T

Jan-Eric Meissner¹, Andreas Korzowski¹, Sebastian Adeberg², Steffen Goerke¹, Nicolas Behl¹, Heinz-Peter Schlemmer³, Jürgen Debus², Mark E. Ladd¹, Peter Bachert¹, and Daniel Paech³

¹*Medical Physics in Radiology, German Cancer Research Center, Heidelberg, Germany*, ²*Radiation Oncology, University Hospital of Heidelberg, Heidelberg, Germany*, ³*Radiology, German Cancer Research Center, Heidelberg, Germany*

Chemical Exchange Saturation Transfer (CEST) offers unique contrasts sensitive to micro environmental information such as protein concentration and pH. Thus CEST could be a promising biomarker to investigate radiotherapy-induced changes in tissue. In this study we examine brain tumor patients in the course of definitive radiotherapy on a 7 T whole-body scanner using the relaxation compensated contrast AREX. We compare the results of CEST imaging to Single Voxel Spectroscopy and high-resolution T₂-weighted imaging.

3751

Computer 89

Voxel-wise comparison of amide proton transfer (APT) weighted image and fluorodeoxyglucose (FDG)-PET in brain tumors with a PET/MR system

Koji Sagiyama¹, Yuji Watanabe², Ryotaro Kamei¹, Sungtak Hong³, Jochen Keupp⁴, and Hiroshi Honda¹

¹*Department of Clinical Radiology, Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan*, ²*Department of Molecular Imaging and Diagnosis, Kyushu University Graduate School of Medical Sciences, Fukuoka, Japan*, ³*Healthcare, Philips Electronics Japan, Philips Research*

Amide proton transfer (APT) imaging has been reported to be useful for assessing malignancy or evaluating treatment efficacy. In this study, we evaluated the validity of APT signals in brain tumors by direct voxel-wise comparison with standardized uptake values (SUVs) from fluorodeoxyglucose positron emission tomography (FDG-PET) on a PET-magnetic resonance (PET/MR) system. APT imaging showed discrepancies with FDG-PET due to structural inhomogeneity, and the correlation between APT signals and SUVs was poor. The correlation was significantly improved after correcting for the apparent diffusion coefficient (ADC). APT/ADC could be a reliable metabolic marker with better correlation with SUVs.

3752

Computer 90

Repeatability study of APT CEST quantification techniques for identification of ischaemic penumbra in stroke

Yunus Msayib^{1,2}, George W. J. Harston³, Yee K. Tee⁴, Fintan Sheerin³, Nicholas P. Blockley⁵, Thomas W. Okell⁵, Peter Jezard⁵, Stephen Payne¹, James Kennedy³, and Michael A. Chappell¹

¹*Engineering Science, University of Oxford, Oxford, United Kingdom*, ²*Centre for Doctoral Training in Healthcare Innovation, University of Oxford, Oxford, United Kingdom*, ³*Radcliffe Department of Medicine, University of Oxford*, ⁴*Department of Mechatronics and Biomedical Engineering, Universiti Tunku Abdul Rahman*, ⁵*Nuffield Department of Clinical Neurosciences, University of Oxford*

The aim of this study was to identify the analysis technique with the optimum repeatability for quantifying APT CEST imaging for use in the clinical setting. The repeatability of eight quantification techniques was assessed across imaging time points in healthy subjects, and between the contralateral hemispheres of stroke patients. Model-based techniques exhibited better repeatability compared to simpler model-free methods, and are thus better-suited for use in clinical imaging at 3T.

Computer 91

Chemical exchange rotation transfer (CERT) of human brain at 3 T

Eugene C. Lin¹, Hua Li¹, Zhongliang Zu¹, Elizabeth A. Louie¹, Xiaoyu Jiang¹, and Daniel F. Gochberg¹

¹*Vanderbilt University Institute of Imaging Science, Nashville, TN, United States*

It has been shown that the changes in chemical exchange saturation transfer (CEST), and specifically amide proton transfer (APT) and nuclear Overhauser effect (NOE), reflect abnormal tissues in tumor, stroke and other diseases. However, quantitative and specific imaging of these effects is challenging due to the influences from asymmetric magnetization transfer and direct water saturation. These obstacles can be avoided with chemical exchange rotation transfer (CERT), which is a pulsed version of CEST with the constraint of constant average power and varying rotation angle. In this study, we present initial CERT results in human brain at 3 T, with the goal of quantifying APT and NOE.

3754

Computer 92

The Chemical Exchange Saturation Transfer (CEST) and Nuclear Overhauser Enhancement (NOE) effects observed in human blood at 7 T under different physiological conditions.

Simon Shah¹, Olivier Mougín¹, Andrew Carradus¹, Nicolas Geades¹, William Morley¹, and Penny Gowland¹

¹Sir Peter Mansfield Imaging Centre, School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom

CEST maps at 7T display higher APT and amine signal from the sagittal-sinus compared to elsewhere in the brain. We investigate CEST and NOE signals detected in *ex-vivo* blood under with varying oxygenation, haematocrit levels, pH and cell structure. Showing that human blood produces significant amounts of CEST and NOE, dominated by the cellular components of blood and independent of blood oxygenation. Clotting and lysing red-blood-cells has no impact on the observed CEST and NOE. We also observed increased APT and NOE with increasing pH. These result are important when interpreting exchange in conditions associated with blood volume change.

3755

Computer 93

Optimization of Amide Proton Transfer (APT) Imaging Experimental Parameters for Brain Tumors: Does RF Saturation Length Always Increase APT Contrast?

Hye-Young Heo^{1,2}, Yi Zhang¹, Shanshan Jiang¹, and Jinyuan Zhou^{1,3}

¹Russell H Morgan Department of Radiology and Radiological Science, Johns Hopkins University, Baltimore, MD, United States, ²F.M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, United States, ³F.M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD, United States

Current APT imaging studies have used a moderate repetition time or relaxation delay to reduce the scan time. However, when a relatively short relaxation delay compared with T_1 is applied, the steady-state water longitudinal magnetization is reduced, resulting in a decrease in APT effect. Therefore, experimental parameters must be optimized on a combination of the RF saturation power, saturation length, and relaxation delay. Here, we quantitatively investigated the dependence of APT and NOE signals on the experimental parameters using Bloch simulations and rat brain tumor models at 4.7 T.

Development of Glutamate-Sensitive CEST at Clinical Field Strength for In Vivo Application

Kristin P. O'Grady^{1,2}, Samantha By^{2,3}, Bailey A. Box^{1,2}, and Seth A. Smith^{1,2,3}

¹Department of Radiology and Radiological Sciences, Vanderbilt University Medical Center, Nashville, TN, United States, ²Vanderbilt University Institute of Imaging Science, Vanderbilt University Medical Center, Nashville, TN, United States, ³Department of Biomedical Engineering, Vanderbilt University, Nashville, TN, United States

Cognitive impairment (CI) is a significant symptom of multiple sclerosis (MS), is the strongest predictor of unemployment in MS patients, and is critical to the decline of quality of life. There is an unmet need for imaging techniques that probe the pathological substrate of CI at a clinically relevant field strength. To address this need, we have investigated the translation of glutamate-sensitive chemical exchange saturation transfer (GluCEST) MRI to 3T, as glutamate abnormalities have been linked to CI in MS. Our results demonstrate the clinical feasibility of GluCEST imaging for application to studying cortical gray matter glutamate signals *in vivo*.

Correction of fat artifacts for unbiased CEST-MRI of the human breast at 7 T

Ferdinand Zimmermann¹, Steffen Görke¹, Johannes Breiting¹, Kerstin Klopries², Johannes Windschuh¹, Heinz-Peter Schlemmer², Mark Edward Ladd¹, Daniel Paech², and Peter Bachert¹

¹Medical Physics in Radiology, German Cancer Research Center, Heidelberg, Germany, ²Division of Radiology, German Cancer Research Center, Heidelberg, Germany

Chemical Exchange Saturation Transfer (CEST) MRI in the mammary gland is affected by the high fat content in the human breast. Chemical shift induced artifacts are visible in the Z-Spectrum. We showed a method to test and verify water-fat separation techniques *in vitro*. Transfer of the gained insights to realize water-only CEST-MRI in the human breast is currently under investigation.

3758

Computer 96

Interleaved B₀-mapping during dynamic Creatine-CEST for correction of temporarily fluctuating B₀ inhomogeneities during plantar flexion exercise at 7T

Esau Poblador Rodriguez¹, Philipp Moser¹, Barbara Dymerska¹, Siegfried Trattnig^{1,2}, and Wolfgang Bogner¹

¹High Field MR Centre, Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Austria, Vienna, Austria, ²Christian Doppler Laboratory for Clinical Molecular MR Imaging, Vienna, Austria

Once the time resolution and specificity of Cr-CEST become comparable with 31P-MRS, it may replace it for the diagnosis of muscular disorders and treatment assessment due to its superior spatial resolution and sensitivity. The need of a complete Z-spectrum acquisition for B₀ inhomogeneity correction limits the achievable time resolution and is unable to track temporal ΔB_0 due to subject movement or B₀ field drifts that occur during a CEST experiment. Temporal B₀ field tracking allows independent B₀ inhomogeneity correction for each z-spectral point, which may substantially improve the reliability of spectral CEST asymmetry analysis.

Computer 49 The inhomogeneous MT (ihMT) technique: Achievements and perspectives

Gopal Varma¹, Olivier M Girard², Valentin H Prevost², Samira Mchinda², Guillaume Duhamel², and David C Alsop¹¹Radiology, Division of MR Research, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States, ²Aix Marseille Univ, CNRS, CRMBM, Marseille, France

The inhomogeneous (ihMT) technique represents a relatively simple addition to MT, but provides a different contrast that is sensitive to the dipolar relaxation time $T_{1\rho}$. A review is provided of: method(s) for its application; considerations for optimizing the ihMT signal; the use of models to obtain quantitative parameters and guide acquisition; and its application *in vivo*.

3760

Computer 50 On the Precision of Myelin Imaging: Characterizing Ex vivo Dog Spinal Cord with MRI and Histology

Manh-Tung Vuong^{1,2}, Tanguy Duval¹, Julien Cohen-Adad^{1,3}, and Nikola Stikov^{1,2}¹NeuroPoly Lab, Polytechnique Montréal, Montréal, QC, Canada, ²Montreal Heart Institute, Montréal, QC, Canada, ³Functional Neuroimaging Unit, CRIUGM, Université de Montréal, Montréal, QC, Canada

There is an ongoing debate in the myelin imaging community about which MR-based biomarker has the greatest precision, sensitivity and specificity to myelin. In this work, we compared several MR-based myelin imaging techniques (quantitative magnetization transfer, myelin water fractions, and macromolecular tissue volume) by evaluating their repeatability and their relation to large-scale histology in dog spinal cord. Qualitatively the contrasts were similar, and all techniques had comparable scan-rescan and correlations with histology. Surprisingly, the correlations between the various myelin measures were almost as high as the scan-rescan correlations. The correlations decreased when only white matter was considered, which could be due to the small dynamic range of the measurement, or due to artifacts related to the preparation and panoramic scanning of the tissue.

3761

Computer 51 Assessment of Lipid Order in Model Myelin Membrane Systems with MT and ihMT

Scott D. Swanson¹, Mario L. Fabilli¹, Dasha I. Malyarenko¹, Ashok Srinivasan¹, Zhongliang Zu², and Daniel F. Gochberg²¹Radiology, University of Michigan, Ann Arbor, MI, United States, ²Radiology, Vanderbilt University, Nashville, TN

We report here a study of MT and enhanced MT (eMT), using dual-sided RF saturation, in model membrane system to measure lipid dynamics and structure in systems of known lipid order. The eMT signal generated by dual-sided RF saturation of phospholipid vesicles is well described by Gaussian line shape and T_{2b} is easily determined. T_{2b} of the lipids is related to the lipid order with $T_{2b}(\text{liquid disorder}) > T_{2b}(\text{liquid order}) > T_{2b}(\text{solid order})$. These tools provide a method to estimate lipid order *in vivo*.

3762

Computer 52 Combining multi gradient echo acquisitions with inversion recovery: estimating the residence time of myelin water from transient MT effects.

Peter van Gelderen¹ and Jeff H Duyn¹¹Advanced MRI, LFMI, NINDS NIH HHS, Bethesda, MD, United States

Combining multi-gradient-echo (MGRE) acquisitions with inversion/saturation preparation pulses allows for separation of white matter signal in several water compartments and estimation of both their T_1 and exchange properties. A model of multiple myelin, myelin water and axonal/interstitial water compartments was implemented, including exchange from and across individual lipid bi-layers. Fitting this model to the inversion prepared MGRE-data resulted in T_1 's and exchange rates for all compartments. The results from a corpus-callosum region of interest indicate that the single layer myelin water residence time is a few hundred microseconds, while the average residence time of all myelin water combined is around 15ms.

3763

Computer 53 Characterization of the power dependency regimes of inhomogeneous Magnetization Transfer (ihMT)

Samira Mchinda¹, Gopal Varma², Valentin H Prevost¹, Arnaud Le Troter¹, Maxime Guye^{1,3}, Jean Pelletier^{1,4}, Jean-Philippe Ranjeva¹, David C Alsop², Guillaume Duhamel¹, and Olivier M Girard¹¹Aix Marseille Univ, CNRS, CRMBM, Marseille, France, ²Radiology, Division of MR Research, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States, ³Aix Marseille Univ, APHM, Hôpital de La Timone, Pôle d'Imagerie Médicale, CEMEREM, Marseille, France, ⁴Aix Marseille Univ, APHM, Hôpital de La Timone, Pôle de Neurosciences Cliniques, Service de Neurologie, Marseille, France

Inhomogeneous magnetization transfer (ihMT) is a new MRI technique that shows promise for myelin imaging. A significant boost of the ihMT signal intensity is achievable when using a concentrated energy deposition scheme. Here we characterized the power dependency of ihMT for various energy deposition schemes (distributed vs. concentrated RF) and we identified distinct regimes with linear, sub-linear and saturated B1 dependency. This has a strong impact on the ihMT response to variable sequence configurations and on the most suitable conditions for different field strengths, e.g. to enhance sensitivity or provide immunity to B1⁺ inhomogeneities.

3764

Computer 54 From in situ to ex vivo: the effect of autolysis and fixation on quantitative MRI markers for myelin

Siawoosh Mohammadi^{1,2,3}, Jan Sedlacik⁴, Martina F Callaghan², Jens Fiehler⁴, Gunther Helms⁵, and Christian Sprenger^{1,6}¹Department of Systems Neuroscience, Medical Center Hamburg-Eppendorf, Hamburg, Germany, ²UCL Institute of Neurology, University College London, London, GA, United Kingdom, ³Department of Neurophysics, Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ⁴Department of Neuroradiology, Medical Center Hamburg-Eppendorf, Hamburg, Germany, ⁵Medical Radiation Physics, Lund University, Sweden, ⁶Department of Engineering, University of Cambridge, United Kingdom

Ex vivo histology remains the gold standard against which MRI biophysical models, e.g. the MR g-ratio which characterises the fraction of a fibre's diameter that is myelinated, are evaluated. The MR g-ratio model requires a measure of myelin density, for which magnetization transfer saturation (MT) has been used as a biomarker. However, changes occurring post mortem, e.g. autolysis, temperature changes and fixation, significantly alter the MRI signal. Here we investigate how these changes impact MT. We found that MT decreased post mortem but greatly increased upon fixation. These effects are similar to reported changes of other established MRI myelin-markers.

3765

Computer 55

On the boost effect of inhomogeneous Magnetization Transfer (ihMT)

Valentin H Prevost¹, Olivier M Girard¹, Samira Mchinda¹, Gopal Varma², David C Alsop², and Guillaume Duhamel¹

¹Aix Marseille Univ, CNRS, CRMBM, UMR 7339, Marseille, France, ²Division of MR Research, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States

A new implementation of inhomogeneous magnetization transfer (ihMT) has recently been introduced, consisting of concentrating the RF energy deposition within the saturation period and demonstrating a significant boost of the ihMT sensitivity. The boost effect has been characterized in this study among different ihMT sequences, species and field strengths and reveals common features. The optimal sequence settings vary with the number of consecutive MT pulses and are presumably related to the timescale of the underlying $T_{1\rho}$ components and magnetization exchange rates.

Computer 56

Accelerating CEST Imaging with Experimental Undersampling and Compressed Sensing

Huajun She¹, Bian Li¹, Joshua S. Greer^{1,2}, Jochen Keupp³, Ivan E. Dimitrov^{1,4}, Ananth Madhuranthakam^{1,5}, Robert Lenkinski^{1,5}, and Elena Vinogradov^{1,5}

¹Radiology, UT Southwestern Medical Center, Dallas, TX, United States, ²Bioengineering, UT Dallas, Dallas, TX, United States, ³Philips Research, Hamburg, Germany, ⁴Philips Healthcare, Gainesville, FL, United States, ⁵Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, TX, United States

Chemical exchange saturation transfer (CEST) is a new contrast mechanism in MRI. However, a successful application of CEST is hampered by its slow acquisition and fast acquisition is desired. Compressed sensing (CS) is powerful for perfect reconstruction of highly undersampled data. Existing works mostly focus on the retrospectively downsampled studies, but few implementation and analysis of truly undersampled scheme with CEST has been reported. This work experimentally implements the random Cartesian undersampled scheme and the golden angle radial sampling sequence for CEST. The results demonstrate influence of experimental conditions that are not accounted for in the retrospectively undersampled studies.

3767

Computer 57

Robust image registration in CEST-acquisitions by exploiting a low-rank plus sparse decomposition of the Z-spectrum

Tobias Wech^{1,2} and Herbert Köstler^{1,2}

¹Department of Diagnostic and Interventional Radiology, University Hospital of Würzburg, Würzburg, Germany, ²Comprehensive Heart Failure Center, University Hospital of Würzburg, Würzburg, Germany

A robust motion correction technique for in vivo CEST-acquisitions is proposed. The algorithm exploits a low-rank plus sparse decomposition of the Z-spectrum to separate signal variations due to different off-resonance preparations from accompanying motion. The method was validated in a phantom study and subsequently used to register a CrCest acquisition of the human thigh during exercise.

3768

Computer 58

snapCEST – A single-shot 3D CEST sequence for motion corrected CEST MRI

Moritz Zaiss¹, Philipp Ehses¹, and Klaus Scheffler¹

¹Magnetic Resonance Center, Max-Planck-Institute for biological cybernetics, Tuebingen, Germany

In this study, we present a single-shot 3D MRI readout that allows acquisition of a CEST prepared volume within 2 s. This makes it possible to correct for motion, which otherwise can cause severe artifacts in CEST imaging.

3769

Computer 59

Multi-Band Enhanced Magnetization Transfer Contrast (MBE-MTC) Preparation

Xiufeng Li¹, Jialu Zhang^{1,2,3}, Wendy Elvendahl¹, Dingxin Wang⁴, Kamil Ugurbil¹, and Gregory J. Metzger¹

¹Radiology-CMRR, University of Minnesota, Minneapolis, MN, United States, ²Interdisciplinary Institute of Neuroscience and Technology, Zhejiang University, Hangzhou, People's Republic of China, ³Department of Biomedical Engineering, Zhejiang University, Hangzhou, People's Republic of China, ⁴Siemens Healthcare, Minneapolis, MN, United States

To overcome the limitations of traditional magnetization transfer contrast (MTC) preparation methods, the Multi-Banded (MB) RF-pulse Enhanced Magnetization Transfer Contrast (MBE-MTC) preparation was proposed by using the multi-banded RF pulses for the MTC preparation. Such an approach has been evaluated via studies in the skeleton muscle, kidneys and the brain with demonstrated benefits. The proposed MBE-MTC preparation provides an alternative way for MTI either for increased MTC or simultaneous and symmetric capture of the MTC or its changes in tissue.

¹Department of Electronic Science, Xiamen University, Xiamen, People's Republic of China, ²Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ³F.M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Research Institute, Baltimore, MD, United States, ⁴Department of Mechanical and Biomedical Engineering, City University of Hong Kong, Hong Kong, People's Republic of China, ⁵Department of Anesthesiology/Critical Care Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States

We demonstrate that off-resonance VDMP can be used as an exchange rate filter to distinguish and quantify the slow- and fast-exchanging components in Z-spectra by applying an appropriate number of pulses and varying the mixing times. The method can be used to extract predominantly fast-exchanging protons by separating out the slow-MTC pool, and provides information about the chemical exchanging species in tissue that conventional MT/CEST technique cannot access.

Chemical Exchange Rotation Transfer Imaging of CEST signal at 2ppm

Zhongliang Zu¹, Elizabeth A Louie¹, Eugene Lin¹, Xiaoyu Jiang¹, Mark D Does¹, John C Gore¹, and Daniel F Gochberg¹

¹Vanderbilt University, Nashville, TN, United States

The CEST signal around 2 ppm may have applications in cancer and muscle imaging and is likely related to an important energy molecule, creatine. In this work, we provide a specific metric to better quantify this signal based on modification of our previously developed CERT approach and an inverse analysis. Results show that the CEST signal at 2 ppm is hypointense in tumors which may be due to decreased creatine content.

3772

Chemical Exchange Saturation Transfer (CEST) with a Multiple Gradient Echo Chemical Shift Imaging (CSI) Sequence

Ken-Pin Hwang¹, Chunxiao Guo², Joshua Yung¹, Christopher J. MacLellan¹, Erik N.K. Cressmann², and R. Jason Stafford¹

¹Department of Imaging Physics, The University of Texas M.D. Anderson Cancer Center, Houston, TX, United States, ²Department of Interventional Radiology, The University of Texas M.D. Anderson Cancer Center, Houston, TX, United States

Chemical exchange saturation transfer (CEST) is observed by applying off-resonance saturation pulses at multiple frequencies and measuring the change in water signal. However, if lipid molecules are present, signals from both species contribute to overall voxel signal, confounding spectral measurement. A multiple gradient echo sequence was developed to simultaneously perform chemical shift imaging with CEST to decouple these signals and measure the independent effect of off-resonance saturation transfer to water. 2D spectra were reconstructed, from which individual water-only z-spectra were obtained. In data from a mixed species phantom, amide proton peaks were clearly visible despite the presence of lipid signal.

Chemical exchange-sensitive MRI at 9.4 T versus 15.2 T: Effect on Sensitivity and Background Signals

Julius Juhyun Chung^{1,2}, Wonmin Choi^{1,3}, Tao Jin⁴, Jung Hee Lee^{1,2,3,5}, and Seong-Gi Kim^{1,2,3}

¹Center for Neuroscience Imaging Research, Institute for Basic Science (IBS), Suwon, Korea, Republic of, ²Samsung Advanced Institute for Health Sciences and Technology, SKKU, Seoul, Korea, Republic of, ³Biomedical Engineering, Sungkyunkwan University, Suwon, Korea, Republic of, ⁴Radiology, University of Pittsburgh, ⁵Radiology, Sungkyunkwan University, Seoul, Korea, Republic of

With chemical-exchange sensitive imaging, increasing field narrows the linewidth of magnetization transfer effects and shifts relative exchange rates (exchange rate vs. chemical shift) toward a slower exchange regime. This study is intended to explore the interplay of contrast mechanisms and sensitivity benefits by comparing phantom and in-vivo data acquired at the fields of 9.4T and 15.2T. The linewidth narrowing effect between the fields is demonstrated in agar phantoms with nicotinamide as well as spectra from the rat cortex. Spectra taken at higher power shows increase of sensitivity by shifting toward a slower exchange regime.

Computer 64

Dual-CEST: a novel 3D-CEST sequence exploiting simultaneous transverse and longitudinal CEST signal encoding.

Robert C. Brand¹, Nicholas P. Blockley¹, Michael A. Chappell², and Peter Jezzard¹

¹Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom, ²Department of Engineering Science, University of Oxford, Oxford, United Kingdom

We propose a novel 3D method called Dual-CEST, which simultaneously captures the CEST contrast stored in the longitudinal and transverse magnetisation of the bulk water. By including ADC events and a hexagonal spoiling scheme during the CEST preparation phase we collected the usually neglected transverse signal, generated by direct water saturation (a method we call NoXi-CEST). The unaffected longitudinal magnetisation is then acquired using a 3D-GRASE readout resulting in one (Dual-CEST) sequence (3:15 min) that provides XY-spectra, in addition to conventional Z-spectra, and producing additional CEST-contrast and B₀-maps without loss of contrast or additional scan time (compared with conventional imaging).

Computer 66

Dominant pH-sensitive amide proton transfer effect during acute ischemic stroke - Quantification of multi-pool contribution to commonly used MTR_{asym} analysis in a rat model of acute stroke

Yin Wu¹, Iris Yuwen Zhou², Jing Zhao¹, and Phillip Zhe Sun²

¹Paul C. Lauterbur Research Center for Biomedical Imaging, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, People's Republic of China, ²Athinoula A. Martinos Center for Biomedical Imaging, Department of Radiology, Massachusetts General Hospital and Harvard Medical School, MA, United States

Routinely used magnetization transfer (MT) asymmetry in measurement of pH-sensitive amide proton transfer (APT) effect is susceptible to concomitant contributions, including semisolid MT and nuclear overhauser effect (NOE). In this study, multi-pool contribution from NOE, MT, CEST at 2 ppm and APT during the acute stroke was resolved with a sum of five Lorentzian functions. Results confirmed the changes in MT and NOE offset each other, and reduction of APT was approximately two-fold of the CEST effect decrease at 2 ppm, dominating the commonly observed pH-sensitive MTR_{asym} change during acute stroke.

3777

Computer 67

Towards Fast Quantitative CEST: A New Model for Quantifying the CEST Effect in the Presence of MT

Alex K Smith^{1,2,3}, Richard D. Dortch^{2,3,4}, and Seth A Smith^{2,3,4,5}

¹FMRIB, University of Oxford, Oxford, United Kingdom, ²Vanderbilt University Institute of Imaging Science, Vanderbilt University, Nashville, TN, United States, ³Department of Biomedical Engineering, Vanderbilt University, Nashville, TN, United States, ⁴Department of Radiology and Radiological Sciences, Vanderbilt University, Nashville, TN, United States, ⁵Department of Ophthalmology, Vanderbilt University, Nashville, TN, United States

Basic models to characterize the CEST effect *in vivo* suffer from competing magnetization transfer (MT) effects. Here, we use qMT to model the CEST effect and derive CEST indices that are independent of MT. Additionally, simultaneously assessing the MT and CEST effects provides more robust estimates of other elements of the MT effect. Simulations and initial *in vivo* findings suggest that combining MT and CEST fitting provides a more accurate fit of CEST z-spectra than a traditional single pool Lorentzian fit, and thus provides estimates of the CEST effect that are not dependent on the MT effect.

3778

Computer 68

Overlap-resolved cest (orCEST) MRI: imaging gaba and glutamate at 16.4T

Frederico Severo¹ and Noam Shemesh¹

¹Chamalimaud Centre for the Unknown, Lisbon, Portugal

Chemical Exchange Saturation Transfer (CEST) affords metabolic imaging at high spatial resolution, especially at ultrahigh fields. However, when spectral overlap exists downfield, metabolite maps may be contaminated by other unwanted signals. Here, we present a methodology termed overlap-resolved-CEST (orCEST), which, through subtraction in CEST_{asym} spectra, provides enhanced specificity. We demonstrate how this technique can be used to resolve the signals of Glutamate and GABA – the Central Nervous System's primary neurotransmitters *in vivo*.

Model-Based Analysis of Partial Z-spectra for Rapid Quantification of Amide Proton Transfer MRI

Paula L. Croal¹, Kevin Ray², Yunus Msayib¹, James Larkin², Brad Sutherland^{3,4}, George Harston³, Andy Baldwin⁵, Alastair Buchan³, Peter Jezzard⁶, James Kennedy³, Nicola Sibson², and Michael Chappell¹

¹Institute of Biomedical Engineering, University of Oxford, Oxford, United Kingdom, ²Oxford Institute for Radiation Oncology, University of Oxford, Oxford, United Kingdom, ³Acute Vascular Imaging Centre & Acute Stroke Programme, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom, ⁴School of Medicine, Faculty of Health, University of Tasmania, Hobart, Australia, ⁵Physical and Theoretical Chemistry Laboratory, Department of Chemistry, University of Oxford, Oxford, United Kingdom, ⁶Oxford Centre for Functional MRI of the Brain, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom

Model-based analysis of APT MRI has been shown to quantitatively outperform conventional approaches such as asymmetry analysis. However clinical application is hindered by slow acquisition of whole z-spectra, and processing times. Here, we demonstrate that by using only a subset of frequency offsets, acquisition and processing time can be reduced by ~70% and ~90%, respectively. Using an MCAO model of ischemic stroke, we demonstrate that our Reduced Frequency Offset approach is able to detect significant differences in APTR* between healthy and ischemic tissue.

Peak RF Optimization for Baseline Enhancement (PROBE) for CEST/NOE with in-vitro application at 7T

Tobias Lenich¹, André Pampel¹, Toralf Mildner¹, Riccardo Metere¹, and Harald E. Möller¹

¹Max-Planck-Institute for Human Cognitive and Brain Sciences, Leipzig, Germany

In CEST/NOE experiments, induced saturation intended for certain metabolites also saturates other moieties, leading to mingled backgrounds in Z-spectra. Precise quantification of endogenous metabolites is impeded by slow acquisition times and confounding background contributions. We present an optimization framework targeting a flattened baseline in Z-spectra, with direct water saturation and non-specific macromolecular contributions fully compensated. Saturation pulse amplitudes as a function of frequency offset were derived using optimal-control-based calculation. Feasibility of this approach is demonstrated in vitro for NOE/CEST in the presence of tissue-like background and accelerated acquisition by distinct offset selection. Experimental results show good agreement with concentration levels.

3781

Computer 71

Volatility analysis for asymmetry-based CEST/NOE evaluation methods in the presence of multi-pool background systems with MT – Application to creatine CEST

Tobias Lenich¹, André Pampel¹, Toralf Mildner¹, Riccardo Metere¹, and Harald E. Möller¹

¹Max-Planck-Institute for Human Cognitive and Brain Sciences, Leipzig, Germany

Here, we aim to demonstrate the effects of complex multi-pool background systems with magnetization transfer (MT) on asymmetry and ratio-based analyses for CEST/NOE experiments. By using creatine in cross-linked BSA as a model, we show effects of background variations on such analyses for creatine CEST (CrCEST) based on experimentally obtained spin system parameters. For changes of up to 50% in background pool fractions, the CrCEST peak was found to change by up to 35% in asymmetry analysis. The necessity of model-based fitting with inclusion of complex background systems in contrast to conventional lineshape-based analysis is outlined.

3782

Computer 72

CEST and NOE signals in ischemic stroke at 9.4T evaluated using a Lorentzian multi-pool analysis: a drop, an increase or no change?

Yee Kai Tee¹, Badrul Abidin¹, Alexandr Khrapitchev², Brad A Sutherland^{3,4}, James Larkin², Kevin Ray², George Harston⁴, Alastair M Buchan⁴, James Kennedy⁴, Nicola R Sibson², and Michael A Chappell⁵

¹Department of Mechatronics and Biomedical Engineering, Universiti Tunku Abdul Rahman, Kajang, Malaysia, ²Cancer Research UK & Medical Research Council Oxford Institute for Radiation Oncology, Department of Oncology, University of Oxford, United Kingdom, ³School of Medicine, Faculty of Health, University of Tasmania, Australia, ⁴Acute Stroke Programme, Radcliffe Department of Medicine, University of Oxford, United Kingdom, ⁵Department of Engineering Science, Institute of Biomedical Engineering, University of Oxford, United Kingdom

CEST and NOE effects in ischemic stroke at 9.4T were studied using a Lorentzian multi-pool approach. It was found that both the CEST and NOE signals had significant changes in region of acute ADC reduction when compared with contralateral tissue. The contrast or relative values to the contralateral tissues of MTR_{asym}(3.5 ppm) was found to correlate moderately strongly with the relative amide signal at 3.5 ppm but not the relative reference signal at -3.5 ppm, suggesting that it should be used in the group analysis in a population-wide basis to assess the change of APT in the ischemic stroke.

Image contrast at sub-millisecond echo times

Jinil Park^{1,2}, Soon Ho Yoon³, Chanhee Lee¹, Jin Mo Goo³, and Jang-Yeon Park^{1,2}

¹Center for Neuroscience Imaging Research, Institute for Basic Science (IBS), Suwon, Korea, Republic of, ²Department of Biomedical Engineering, Sungkyunkwan University, Suwon, Korea, Republic of, ³Department of radiology, Seoul National University Hospital, Seoul University College of Medicine, Seoul, Korea, Republic of

Some contrast mechanisms like in- and out-of-phase contrasts of fat and water come into play at sub-millisecond echo times(TE) at high field strengths above 3T, and under-recognition of them can lead to misunderstanding of signal intensities and inappropriate interpretation of normal and disease pathology. Here the TEs including the sub-millisecond ones were estimated at various field strengths and it was demonstrated by phantom and human lung imaging that contrast mechanisms are apparently seen at the sub-millisecond TE and thus should not be overlooked at high field strengths when using UTE imaging techniques that can cover the range of sub-millisecond TE.

High Resolution Magic Angle Spinning (HR-MAS) NMR characterization of inhomogeneous magnetization transfer (ihMT) responsive samples

Olivier M. Girard¹, Victor Carvalho^{1,2}, Pierre Thureau², Valentin H. Prevost¹, Samira Mchinda¹, Gopal Varma³, David C. Alsop³, and Guillaume Duhamel¹

¹Aix Marseille Univ, CNRS, CRMBM, Marseille, France, ²Aix Marseille Univ, CNRS, ICR, Marseille, France, ³Division of MR Research, Beth Israel Deaconess Medical Center, Harvard Medical School

Inhomogeneous magnetization transfer (ihMT) is a promising technique for central nervous system imaging. Although ihMT signal is mostly observed in myelinated tissues, weaker ihMT signal may be revealed in other biological tissue. The fundamental relationship between the underlying NMR lineshape and the ihMT signal is still an open question. Here we investigate high resolution magic-angle spinning (HR-MAS) NMR to provide insight into the mechanisms underpinning line broadening of ihMT responsive samples. The resulting spectra evidence different dipolar Hamiltonian components contributing to line broadening and support ihMT as being dominated by inhomogeneous interaction in myelinated tissues.

¹University of Aberdeen, Aberdeen, United Kingdom, ²U1205 BrainTech Lab, INSERM, Grenoble, France, ³INAC-SCIB, CEA, Grenoble, France

FFC-NMR is a unique tool for the measurements of molecular dynamics in the range of nano- to microseconds. With the development of FFC-MRI scanner, it is now possible to investigate new contrasts using field-dependant variations of T₁ to obtain quantitative markers in diseases. In this work we investigate what information FFC-NMR can provide in the context of glioma, using frozen human brain resection from glioma and epileptic surgery. We found that the quadrupolar peaks and T₁ dispersions values may be useful biomarkers.

3791

Computer 105

Optimisation of Fast Field-Cycling MRI pulse sequences by numerical simulation.

Nicholas R. Payne¹, Lionel M. Broche¹, and David J. Lurie¹¹University of Aberdeen, Aberdeen, United Kingdom

Fast Field-Cycling MRI (FFC-MRI) has the ability to access contrast invisible to conventional scanners – that resulting from the dependence of T_1 on magnetic field strength. Simulating FFC-MRI sequences by iteratively applying the Bloch equations as the magnetic field strength changes with time was found to give highly accurate predictions of signal intensity at the end of each cycle. This information was used to optimise parameters of the FFC-MRI scans.

3792

Measurement of R2 dispersion profiles using Fast Field Cycling MRI

Nicolas Chanet¹, Geneviève Guillot¹, and Ludovic de Rochefort²

¹IR4M (Imagerie par Résonance Magnétique Médicale et Multi-modalités), Univ. Paris-Sud, CNRS, UMR8081, Université Paris-Saclay, Orsay, France, ²Aix Marseille Univ., CNRS, CRMBM UMR 7339, Marseille, France

Fast Field Cycling (FFC) MRI enables rapid and precise relaxometry measurements as a function of magnetic field B_0 . Up to now, it was possible to measure longitudinal R_1 -NMRD profiles and to generate innovative R_1 -dispersive contrasts. However, the ability to measure transverse R_2 -NMRD profiles has still to be investigated. Here, a spin-echo based FFC sequence is developed to measure R_2 -dispersion, and is applied to ferritin and Gd-DOTA in the range 1.15 to 1.85 T. It is shown that measurements of R_2 dispersion could be obtained accurately with the FFC-MRI technology.

Computer 117

Estimation of arterial blood T₁ during hyperoxic gas-mixture breathingErin K Englund¹, Zachary B Rodgers¹, Hyunyeol Lee¹, and Felix W Wehrli¹

¹Department of Radiology, University of Pennsylvania, Philadelphia, PA, United States

Hyperoxia gas mixture breathing causes additional oxygen to be dissolved in blood plasma thereby shortening the T₁ of arterial blood (T_{1a}). Here, we propose a method estimate T_{1a} during hyperoxia gas breathing by solving a perfusion quantification model for T_{1a} given CBF measured during hyperoxia via phase contrast (PC) of the feeding arteries in the neck. The ratio between PC-based total CBF and ASL-based regional CBF was first determined at baseline, and then applied to normalize the expected ASL-based CBF during hyperoxia. T_{1a} was estimated as 1.46±0.09 s during hyperoxia gas mixture breathing, in reasonable agreement with previous reports.

Tagging distance dependent Z-spectrum (TADDZ) for ASL MRI free from B₀-inhomogeneity induced errorsFrederick C. Damen^{1,2}, Rong-Wen Tain^{1,2}, Weigo Li³, Xiaohong Joe Zhou^{1,2}, Leon Tai⁴, and Kejia Cai^{1,2}

¹Radiology, University of Illinois at Chicago, Chicago, IL, United States, ²Center for Magnetic Resonance Research 3T Program, University of Illinois at Chicago, Chicago, IL, United States, ³Research Resources Center, University of Illinois at Chicago, Chicago, IL, United States, ⁴Anatomy and Cell Biology, Chicago, IL, United States

Arterial spin labeling (ASL) MRI, based on endogenous contrast from blood water, is used for research and diagnosis of cerebral vascular conditions. However, artifacts due to imperfect imaging conditions such as B₀ inhomogeneity could lead to variations in the quantification of cerebral blood flow (CBF). In this study, we investigated the CBF variation artifacts due to B₀-inhomogeneity using Signal Targeting with Alternating Radio frequency (STAR) based ASL. We developed a novel technique, TADDZ, similarly to the corrections for chemical exchange saturation transfer (CEST) experiments, to remove the B₀ inhomogeneity induced CBF artifacts.

A 3D printed perfusion phantom for quality controlled measurement of arterial spin labeled perfusion

Joshua S. Greer^{1,2}, Xinzeng Wang², Keith Hulsey², Robert E. Lenkinski^{2,3}, and Ananth J. Madhuranthakam^{2,3}

¹Bioengineering, UT Dallas, Richardson, TX, United States, ²Radiology, UT Southwestern Medical Center, Dallas, TX, United States, ³Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, TX, United States

Arterial spin labeling (ASL) is a rapidly growing area of interest, primarily because of its ability to provide non-contrast quantitative perfusion maps. For the technique to be adopted for clinical use, these quantitative measurements need to be accurate and robust, which will require a quality controlled perfusion phantom to ensure consistency for different magnet strengths and manufacturers. In this study, we demonstrate a 3D printed perfusion flow phantom that can be easily replicated, and used to test the precision and repeatability of ASL perfusion measurements.

Computer 120

Dynamic Magnetic Resonance Imaging with Vaginal and Rectal Contrast for the Observation of Vaginal Vault and Rectocele

Huici Zhu¹, Jianyu Liu¹, and Lizhi Xie²

¹Radiology Department of Peking University Third Hospital, Beijing, People's Republic of China, ²GE Healthcare, MR Research China, Beijing, People's Republic of China

To determine which method is better for the observation of vaginal vault and rectocele, this research compared the routine dynamic MRI with the dynamic MRI with vaginal and rectum contrast. There was statistically significant difference between the dynamic MR imaging and dynamic MR imaging with vaginal and rectum contrast. For the observation of vaginal vault prolapse and rectocele, the dynamic MR imaging with vaginal and rectum contrast was better than the routine method.

NUFFT: Fast Auto-Tuned GPU-Based Library

Teresa Ou¹, Frank Ong¹, Martin Uecker², Laura Waller¹, and Michael Lustig¹

¹University of California, Berkeley, Berkeley, CA, United States, ²University of Göttingen, Göttingen, Germany

We present a fast auto-tuned library for computing non-uniform fast Fourier Transform (NUFFT) on GPU. The library includes forward and adjoint NUFFT using precomputation-free and fully-precomputed methods, as well as Toeplitz-based operation for computing forward and adjoint NUFFT in a single step. Computation of NUFFT depends heavily on gridding parameters, desired accuracy, trajectory type, amount of undersampling, and level of precomputation. The library automatically chooses optimal gridding parameters and algorithms, and it can be easily extended to include implementations from other libraries. The library allows researchers to accelerate iterative reconstructions without the difficulties of choosing optimal parameters and algorithms.

[MRIQC: automated assessment and quality reporting of MRI scans](#)

Oscar Esteban¹, Craig Anthony Moodie¹, William Triplett², Russell Alan Poldrack¹, and Krzysztof Jacek Gorgolewski¹

¹Department of Psychology, Stanford University, Stanford, CA, United States, ²Department of Physical Therapy, University of Florida

Assessing the quality of MRI is necessary and time-consuming. MRIQC automates the quantification extracting a number of image quality measures (IQMs), and eases the individual inspection through specialized visual reports. MRIQC supports T1w, fMRI and dMRI brain images. MRIQC is an easy to use, "plug-and-play" tool, since it is multi-platform (including desktop and high performance clusters), and BIDS- and BIDS-apps compliant. The IQMs extracted automatically will yield unbiased exclusion criteria in MRI analyses.

Computer 4

[Simulation Reveals Evidence for Bias in Parameter Estimates for Compressed Sensing of Temporally Dynamic Systems](#)

Nathan Murtha^{1,2}, James Rioux^{1,2,3}, Olliver Marriott², Chris Bowen^{1,2,3}, Sharon Clarke^{1,2,3}, and Steven Beyea^{1,2,3}

¹Physics and Atmospheric Science, Dalhousie University, Halifax, NS, Canada, ²Biomedical Translational Imaging Centre, QE2 Health Sciences Centre, Halifax, NS, Canada, ³Diagnostic Radiology, Dalhousie University, Halifax, NS, Canada

There exists no objective framework for assessment of acquisition and reconstruction methods in compressed sensing (CS) MRI involving temporal dynamics. We propose a simulation framework to address this gap. Image quality was assessed using two quantitative metrics, and temporal parameters were recovered using least-squares fitting. CS regularization weighting was varied to determine the effect on both image quality and accuracy of recovered temporal dynamic parameters. Image quality metrics displayed distinct optima, though bias, dependent on the underlying temporal dynamics, was introduced to temporal parameter estimates. These results support the need for an objective tool to characterize CS MRI methodologies.

Computer 5

[Developing an automated MRI Decision support system: MIROR a non-region specific modular analysis toolbox](#)

Niloufar Zarinabad^{1,2}, Karen Manias^{1,2}, Katharine Foster², and Andrew Peet^{1,2}

¹University of Birmingham, Birmingham, United Kingdom, ²Birmingham children hospital, Birmingham, United Kingdom

There is a need for an MRI diagnostic analysis-tool which can provide healthcare investigators with a platform for extraction of relevant information and allow for comparison with similar cases to aid decision-making. The aim of this study was to develop a modular, non-region-specific Medical-Image-Region-of-interest-analysis-tool and Repository (MIROR) in order for advanced MRI techniques to become a part of the clinical routine. Here, the first development phase is presented as applied to diffusion-weighted-imaging of pediatric body-tumors combined with comparison to a repository of cases. MIROR acts as a foundation which can be extended to more advanced image-analysis and sophisticated decision-support.

Computer 6

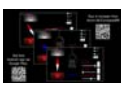

[Implementation of a parallel processing pipeline of multi-channel phase data](#)

Timothy M Whelan¹, Martyn L Klassen¹, Igor Solovey¹, Junmin Liu¹, and Maria Drangova^{1,2}

¹Imaging Research Laboratories, Robarts Research Institute, London, ON, Canada, ²Dept. of Medical Biophysics, Schulich School of Medicine & Dentistry, Western University, London, ON, Canada

Evidence exists to show that phase unwrapping performed before channel combination results in fewer artifacts (singularities, open ended fringe lines) than when phase unwrapping occurs after channel combination. We have implemented a fast and efficient pipeline designed to enable processing of multi-channel phase data. Specifically, non-iterative phase unwrapping and channel combination are employed within the pipeline that links the MR scanner to a DICOM server, which displays the final combined images, while preserving all metadata.

- 3813 **Computer 7** [An abstraction layer for simpler EPIC pulse programming on GE MR systems in a clinical environment](#)
Stefan Skare^{1,2}, Enrico Avventi¹, Ola Norbeck¹, and Henric Ryden¹

¹Neuroradiology, Karolinska University Hospital, Stockholm, Sweden, ²Karolinska Institutet, Stockholm, Sweden
- A C-library that simplifies EPIC pulse programming on GE MR systems is presented, containing a large set of new structs and functions for EPIC. Three pulse sequences have been developed (GRE, FSE and EPI) using this library with EPIC. These sequences have most of the functionality expected in a clinical neuro MRI setting, including arbitrary scan planes, full user interface support, online/offline reconstruction, and with common generic sequence plugins/modules such as SpatialSat, FatSat, and Inversion. The KSFoundation library, pulse sequences and sequence modules can be used to quickly develop new pulse sequences with reduced amount of code.
-

Annika Liebgott^{1,2}, Sergios Gatidis¹, Petros Martirosian¹, Fritz Schick¹, Bin Yang², and Thomas Küstner^{1,2}

¹Diagnostic and Interventional Radiology, University Hospital of Tübingen, Tübingen, Germany, ²Institute of Signal Processing and System Theory, University of Stuttgart, Stuttgart, Germany
- In various image processing applications, finding appropriate mathematical descriptions which reflect or extract characteristics of the underlying content from acquired MR images is an important and crucial step. There exists a variety of features which can be used for MRI, but which ones are the most meaningful depends on the underlying scientific or diagnostic question/application as well as the image itself. To reduce the time spent searching for, implementing and testing features for a specific application, we provide a toolbox of features along with a GUI to easily choose and extract them, which will be made publicly available.
-
- 3816 **Computer 10** [PyMRT and DCMPI: two new Python packages for MRI data analysis](#)
Riccardo Metere¹ and Harald E. Möller¹

¹NMR Unit, Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany
- Among the many packages available for data analysis in magnetic resonance imaging, only few offer specific tools for quantitative MRI. Additional limitations often come from implementation details, where fast development cycles and code maintainability can be difficult to achieve. Recently, Python has emerged as an ideal tool for the development of software for scientific computing. Here, we propose two easily extensible software packages implemented in Python: PyMRT for the analysis of MRI data, notably for quantitative applications; DCMPI for simplifying and automatize portions of the data collection step.
-
- 3817 **Computer 11** [A Matlab-based graphical user interface for processing dynamic CEST-MRI data](#)
Neil Wilson¹, Hari Hariharan¹, and Ravinder Reddy¹

¹CMROI, University of Pennsylvania, Philadelphia, PA, United States
- A graphical user interface was designed in Matlab to process dynamic CEST-MRI experiments. Field corrections due to B0 and B1 inhomogeneities are applied, ROIs are taken, CEST signal is fitted, and high quality figures are produced with minimal user input. Data is presented for an exercise-induced skeletal muscle creatine elevation experiment though the GUI is highly customizable.
-
- 3818 **Computer 12** [Day 1 of MRI and NMR education: Interactive visualization of MR basics](#)
Lars G. Hanson^{1,2}

¹Center for Magnetic Resonance, DTU Elektro, Technical University of Denmark, Kgs. Lyngby, Denmark, ²Danish Research Centre for MR, Centre for Functional and Diagnostic Imaging and Research, Copenhagen University Hospital, Hvidovre, Denmark
- It is challenging to teach and learn the very basics of Magnetic Resonance as used in NMR and MRI. A simple approach is demonstrated that provides accurate understanding of basic MR phenomena, also for non-technical students. An interactive free simulation tool is used that invites student exploration of Compass and Nuclear MR via browser or app. This CompassMR simulator offers you a unique opportunity to finally make anybody intuitively understand MR in minutes, even your parents who always wanted to know what you are doing.
-
- 3819 **Computer 13** [IMAGING ON THE EARTH'S MAGNETIC FIELD](#)
Ruth Agjobu-Alafun¹, Steven Sourbron¹, and Leonidas Georgiou¹

¹Division of Biomedical Imaging, University of Leeds, Leeds, United Kingdom

This educational abstract is aimed at providing a better understanding of NMR principles and optimisation of scan parameters for imaging using graphical illustrations and images generated with the Terranova-MRI EFNMR system. It is beneficial to clinicians who seek a more intuitive way to educate themselves with regards to MRI; to students who need hands on experience to gain a better understanding of the underlying mechanisms of signal and image formation; and to academic researchers who are looking to introduce alternative teaching methods of MRI techniques in their institutions.

Hough-transform based detection of vascular structures applied to automate and accelerate planning of super-selective Arterial Spin Labeling

Thomas Lindner¹, Olav Jansen¹, and Michael Helle²

¹Clinic for Radiology and Neuroradiology, University Hospital Schleswig-Holstein, Kiel, Germany, ²Tomographic Imaging Department, Philips Research, Hamburg, Germany

Super-selective Arterial Spin Labeling (ASL) is a technique to perform non-contrast enhanced flow territory mapping. Prior to image acquisition, the labeling focus has to be positioned on each artery of interest separately. Depending on the arterial architecture, this process can be time-consuming, especially for untrained operators. In this study, an algorithm for automated vessel detection and planning is introduced to accelerate the planning procedure of super-selective ASL measurements, which is based on the Hough transform to detect circular structures (i.e. arteries) on a transversal time-of-flight (TOF) scan.

3824

Computer 18

Advanced platform-independent MR prototyping: From EPI to Arterial Spin Labeling without code compilation

Thorsten Honroth¹, Cristoffer Cordes^{1,2}, Saulius Archipovas¹, Federico von Samson-Himmelstjerna^{1,2}, Matthias Günther^{1,2,3}, and David Porter¹

¹Fraunhofer MEVIS, Bremen, Germany, ²University of Bremen, Bremen, Germany, ³mediri GmbH, Heidelberg, Germany

A previously demonstrated, platform-independent rapid prototyping environment for MR sequences that provides a workflow without code compilation has been extended with features that allow the creation of a FAIR Arterial Spin Labeling (ASL) sequence. Also, the calculation code for the necessary FOCI inversion pulse, which is protocol dependent and which needs to be executed during runtime on the scanner, can be implemented compilation-free using a scripting language.

An Automated Phantom QA procedure for the Rhineland Study

Eberhard Daniel Pracht¹, Christian Schmickler¹, Monique Breteler¹, and Tony Stoecker^{1,2}

¹German Center for Neurodegenerative Diseases, Bonn, Germany, ²Department of Physics and Astronomy, University of Bonn, Bonn, Germany

For the Rhineland study, a fully automated phantom QA procedure was developed to monitor the quality characteristics of the MRI scanners. Various QA metrics are investigated to characterize scanner stability and performance over time and across different sites. To ensure measurement reproducibility and consistency standardized phantoms were developed and a dedicated QA protocol as well as a processing pipeline was implemented. The QA scans are acquired each day after the last subject to be able to detect data inconsistencies and hardware defects as soon as possible. This ensures high-throughput data collection with minimal data loss.

Implementation of a Dual Parameter Segmentation Tool for Identification of Brown Adipose Tissue on Magnetic Resonance Imaging

David Reading¹, Dana Mathews², Yee Ng¹, Binu Thomas³, Orhan Oz², Jonathan Graff⁴, and Takeshi Yokoo⁵

¹Radiology, UT Southwestern Medical Center, Dallas, TX, United States, ²Radiology, Division of Nuclear Medicine, UT Southwestern Medical Center, Dallas, TX, United States, ³Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, TX, United States, ⁴Department of Developmental Biology, UT Southwestern Medical Center, Dallas, TX, United States, ⁵Radiology, Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, TX, United States

Defining regions of brown adipose tissue (BAT) on MRI remains challenging. Dissemination of existing methods is complicated by propriety algorithms, variability between institutions, and the need for time consuming manual segmentation. In this pilot imaging study, we implemented an online segmentation tool for the open-source OsiriX DICOM viewer platform (Pixmeo, Geneva) that can be used to identify regions of BAT on MRI through simultaneous fat fraction and T2* thresholding automatic segmentation. Since an OsiriX plugin is easily distributable and usable across different centers, our tool may facilitate future research studies of BAT using MRI.

3829

Computer 23

An Image Simulation Tool for 3D TSE Including Flow Effects

John W Grinstead¹, Gregor Koerzdoerfer², Gerhard Laub², William Rooney³, and Mathias Nittka²

¹Siemens Healthcare, Portland, OR, United States, ²Siemens Healthcare, ³Oregon Health & Science University, Portland, OR, United States

A 3D TSE simulation tool designed as both an educational tool as well as a guide for optimizing protocols is described. The pulse sequence protocol user interface triggers integrated Bloch simulations for a user-defined set of tissues based on current protocol settings including the variable flip angle scheme and reordering mode. The tool models tissue T1 & T2 as well as flow effects. We demonstrate applicability to the issue of flow-induced signal loss in CSF and compare simulations to in vivo measurements. The effects of parameter changes that would otherwise require lengthy in vivo comparisons can now be easily explored.

3830

Computer 24

SNR and volume characterization of RF coils: A simple procedure and an automatic post-processing tool for a straightforward comparison

laurent Mahieu-Williams¹, Sophie Gaillard¹, Denis Grenier¹, Radu Bolbos², Jean-Baptiste Langlois², Franck Lambertson², Sorina Camarasu-Pop¹, and Olivier Beuf¹

¹Univ.Lyon, CREATIS, CNRS UMR 5220, Inserm U1206, INSA-Lyon, UJM- Saint Etienne Université Claude Bernard Lyon 1, Villeurbanne, France, Lyon, France, Metropolitan, ²CERMEP – imagerie du vivant, Lyon, France, Lyon, France, Metropolitan

To choose the most suitable RF coil available for an MRI study, we propose a procedure which uses a calibrated phantom, a 3D gradient-echo sequence, and an automatic post-processing tool available on the web. This tool generates a report which contains the measurement of a SNR with uniform volumes located in the depth. The post-processing could be done on MR images acquired on most main MRI vendors (Siemens, GE, Philips and Bruker) with prior verification of applied scaling or filtering. RF coil characterization results performed on at 4.7T and 7T were compared. The tool can be used for quality control.

[MR Fingerprinting ASL: multi-slice acquisition, sequence optimization, and validation with DSC](#)

Pan Su^{1,2}, Yang Li^{1,2}, Deng Mao^{1,2}, Wenbo Li^{1,3}, Qin Qin^{1,3}, Jay J. Pillai¹, and Hanzhang Lu¹

¹Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins University, Baltimore, MD, United States, ²Graduate School of Biomedical Sciences, The University of Texas Southwestern Medical Center, Dallas, TX, United States, ³F.M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD, United States

MR Fingerprinting (MRF) based Arterial Spin Labeling (ASL) has been recently proposed as a new approach to measure multiple hemodynamic parameters in a single scan. However, the previous implementation of MRF-ASL has several limitations, including a single-slice-only acquisition, incomplete optimization of the sequence, and an absence of comparison with existing techniques such as Look-Locker ASL and dynamic-susceptibility-contrast (DSC) MRI. In this work, we conducted a series of six studies to fill these technical gaps: we optimized several key imaging parameters in MRF-ASL and compared the results to existing methods.

3832

Computer 26

[Using a Novel Multiband Multi-Echo Simultaneous ASL/BOLD Sequence to Measure Cerebrovascular Reactivity](#)

Alexander D. Cohen¹, Andrew S. Nencka¹, and Yang Wang¹

¹Radiology, Medical College of Wisconsin, Milwaukee, WI, United States

A multiband, multi-echo simultaneous ASL/BOLD sequence was developed and used to estimate cerebrovascular reactivity (CVR) using a breath hold (BH) task. In addition, both the BOLD and ASL data were denoised using multi-echo independent component analysis (ME-ICA). ICA was used to extract the BH activation component from the data, which was then correlated with the whole brain. CVR was estimated as the percent signal change from the BH task. Denoising resulted in increased BH activation and more robust CVR maps. Furthermore, the data-driven approach used here eliminates the need to model for the complicated BH response.

3833

Computer 27

[Comparison of Methods for Simultaneous Multi-Slice Balanced SSFP Imaging](#)

Yuan Zheng¹, LeLe Zhao², Cong Zhang², Jian Xu¹, Ruchen Peng³, and Weiguo Zhang²

¹UIH America, Houston, TX, United States, ²Shanghai United Imaging Healthcare Co., Ltd, Shanghai, People's Republic of China, ³Medical Imaging Center, Beijing Luhe Hospital Affiliated to Capital Medical University, Beijing, People's Republic of China

Many previously reported SMS-bSSFP sequences use RF phase modulation for slice shifting, which inevitably shifts the bSSFP frequency band and is thus susceptible to banding artifacts. Another slice-shifting method is to modulate slice-select dephasing/rephasing gradients. We have studied these two strategies and showed that gradient modulation is more advantageous, since it does not modify the RF phase cycling scheme and bSSFP frequency selectivity is kept the same for all slices. We have acquired phantom and in-vivo head images using both approaches, and demonstrated that gradient modulation does not introduce banding artifacts and produces high quality images.

3834

Computer 28

[Tailored 3D RF pulses for g-factor reduction in phase-constrained simultaneous multislice imaging](#)

Ádám Kettinger^{1,2}, Stephan A. R. Kannengiesser³, Felix A. Breuer⁴, Zoltán Vidnyánszky¹, and Martin Blaimer⁴

¹Brain Imaging Centre, Research Centre for Natural Sciences, Hungarian Academy of Sciences, Budapest, Hungary, ²Department of Nuclear Techniques, Budapest University of Technology and Economics, Budapest, Hungary, ³MR Application Predevelopment, Siemens Healthcare GmbH, Erlangen, Germany, ⁴Magnetic Resonance and X-ray Imaging Department, Fraunhofer Development Center X-ray Technology (EZRT), Würzburg, Germany

Simultaneous multislice imaging techniques are widely used to accelerate the acquisition process, however, non-ideal coil geometries can introduce noise enhancement. This effect can be reduced by using the virtual-conjugate-coil technique, in which case the g-factors will be dependent of the object background phase. It has been shown that an optimal phasemap exists that minimizes the g-factors. We have used 3D tailored RF pulses to approximate the optimal phase distribution in each simultaneously acquired slice to reduce the noise amplification in phantom and also in vivo. Our results imply that g-factors can be reduced significantly while flip angle homogeneity remains reasonable.

3835

Computer 29

[Quantitative Susceptibility Mapping Using 2D Simultaneous Multi-slice Gradient-echo Imaging at 7T](#)

Wei Bian¹, Adam Bruce Kerr², Kongrong Zhu², Paymon Rezaii¹, Maged Goubran¹, Christopher Lock³, May Han³, Yi Wang⁴, Zhe Liu⁴, Sherveen Parivash¹, Brian Rutt¹, and Michael Zeineh¹

¹Department of Radiology, Stanford University, Stanford, CA, United States, ²Department of Electrical Engineering, Stanford University, Stanford, CA, United States, ³Department of Neurology and Neurological Sciences, Stanford University, Stanford, CA, United States, ⁴Department of Radiology, Weill Cornell Medical College, New York, NY

A 2D multi-echo simultaneous multi-slice (SMS) gradient-echo imaging sequence was implemented for simultaneous anatomical imaging, R2* mapping and quantitative susceptibility mapping (QSM). Imaging acceleration in the slice direction speeds up the sequence to clinical scan times while using a longer TR and larger flip angle compared to 3D imaging. Evaluation from both healthy and multiple sclerosis subjects showed that, using the same acquisition time and imaging resolution as a 3D sequence, the proposed sequence improved tissue susceptibility contrast, suggesting 2D SMS GRE imaging may be a viable alternative for clinical applications of susceptibility-based imaging.

3836

Minimum-Duration Parallel Transmit Pulses for Simultaneous Multislice Imaging

Mihir Pendse¹ and Brian K Rutt¹

¹Stanford University, Stanford, CA, United States

We describe a procedure for obtaining minimum duration parallel transmit pulses for simultaneous multislice imaging. The strategy involves a combination of the IMPULSE parallel transmit pulse design algorithm for mitigating local SAR hotspots and enforcing flip angle homogeneity; an optimal control algorithm for intelligent design of slice selective subpulse shape with minimum power; and time-optimal VERSE for reducing peak power with minimum increase in pulse duration. Results indicate a reduction in pulse duration by a factor of 4.9 compared to a pTx-SMS pulse designed with conventional techniques.

3837

Computer 31

Super Resolution Motion Correction (SUPREMO) using Simultaneous Multi-Slice EPI based fMRI

Simultaneous multi-slice triple-echo steady-state (SMS-TESS) T_1 , T_2 , PD, and B_0 mapping in the human brain

Rahel Heule^{1,2}, Zarko Celicanin^{1,2}, Sebastian Kozerke³, and Oliver Bieri^{1,2}

¹Division of Radiological Physics, Department of Radiology, University of Basel Hospital, Basel, Switzerland, ²Department of Biomedical Engineering, University of Basel, Basel, Switzerland, ³Institute for Biomedical Engineering, University and ETH Zurich, Zurich, Switzerland

Triple-echo steady-state (TESS) has so far been investigated mainly as a particular robust and intrinsically B_1 -insensitive method for T_2 relaxation time mapping. Here, its potential for fast simultaneous multi-parametric (T_1 , T_2 , PD, and B_0) mapping of human brain tissues from a single scan is explored. TESS imaging is performed in 2D mode to mitigate motion sensitivity in the brain and accelerated by simultaneous multi-slice (SMS) imaging using CAIPIRINHA to excite two slices simultaneously providing similar SNR in half the acquisition time as compared to sequential single-slice imaging.

3840

Computer 34

Snapshot whole-brain T_1 mapping using 2D multi-slice variable flip angle spiral imaging with steady-state preparation

Rahel Heule^{1,2}, Josef Pfeuffer³, and Oliver Bieri^{1,2}

¹Division of Radiological Physics, Department of Radiology, University of Basel Hospital, Basel, Switzerland, ²Department of Biomedical Engineering, University of Basel, Basel, Switzerland, ³Siemens Healthcare, Application Development, Erlangen, Germany

Spiral imaging substantially shortens MR fingerprinting acquisitions to tolerable scan times. Also more traditional "state-of-the-art" parametric mapping techniques can potentially benefit from the speed-up ability of fast spiral trajectories as opposed to Cartesian sampling. Here, a variable flip angle T_1 quantification approach based on an interleaved 2D spiral multi-slice spoiled gradient echo sequence is combined with a steady-state preparation scheme. The investigated method offers accurate whole-brain T_1 determination at clinically relevant resolution in only half a minute (including the B_1 mapping scan in about 40 s) with an acceleration factor of an order of magnitude compared to conventional Cartesian sampling.

Improvements in Simultaneous Multislice Imaging Through the Use of SPIRIT and Virtual Conjugate Coils

Nikolai J Mickevicius¹ and Eric S Paulson²

¹Biophysics, Medical College of Wisconsin, Milwaukee, WI, United States, ²Radiation Oncology, Biophysics, Radiology, Medical College of Wisconsin, Milwaukee, WI, United States

Simultaneous multislice (SMS) imaging is an attractive solution for accelerating MR acquisition due to its higher inherent SNR. However, further acceleration of SMS images along the phase encoding direction results in increased noise amplification. We demonstrate here the advantages of a combined virtual conjugate coil based phase-constrained SPIRiT reconstruction to minimize the g-factor penalty associated with highly accelerated SMS acquisitions.

Computer 36

Slice-GRAPPA calibration using pre-scan data and application to simultaneous multi-slice PROPELLER

Kun Zhou¹, Wei Liu¹, Fang Dong¹, and Shi Cheng¹

¹Siemens Shenzhen Magnetic Resonance Ltd., Shenzhen, People's Republic of China

In simultaneous multi-slice imaging technique, the kernels used for unfolding the collapsed slices are estimated using integrated or separated reference scans, which require additional scan time. In this work a slice-GRAPPA calibration method utilizing the pre-scan data is developed to save the time for acquiring training data. This method has been applied to slice accelerated PROPELLER sequence. The result shows that the proposed method can correctly fit the SG kernel and reconstruct the slice undersampled images.

An optimized slice-GRAPPA reconstruction method to reduce leakage artifacts in small-animal multiband imaging

Hiroshi Toyoda¹, Sosuke Yoshinaga², Naoya Yuzuriha², Mitsuhiro Takeda², and Hiroaki Terasawa²

¹Center for Information and Neural Networks, National Institute of Information and Communications Technology, Suita, Japan, ²Department of Structural Biomedicine, Kumamoto University, Kumamoto, Japan

Accurate slice separation for simultaneous multi-slice acquisition continues to be challenging, especially when animal scanners equipped with relatively few receiver coil elements are used. We propose an optimized slice-GRAPPA method to reconstruct the dual-band EPI of rat brains, in which the size-optimized kernel was iteratively estimated to reduce artifacts. The reconstructed images were evaluated in terms of inter-slice leakage, g-factor, and temporal variation across the repetitions. With the proposed method, inter-slice leakage artifacts and the g-factor were reduced, and the average signal-to-noise ratio was improved. Thus, the total reconstruction accuracy was improved in the multiband EPI in a small animal study.

SOMS: Simultaneous Orthogonal Multi-Slice Imaging

Sebastian Rosenzweig^{1,2} and Martin Uecker^{1,2}

¹Diagnostische und Interventionelle Radiologie, University Medical Center Göttingen, Göttingen, Germany, ²Partner site Göttingen, German Centre for Cardiovascular Research (DZHK), Göttingen, Germany

Simultaneous multi-slice (SMS) MRI has become a popular technique in both research and clinical practice, as it provides information about multiple slices at the time of a conventional single-slice measurement. For technical reasons, SMS is commonly limited to the acquisition of parallel slices. Here, we propose a new Cartesian sequence for the simultaneous excitation of orthogonal slices. We dub this technique simultaneous orthogonal multi-slice (SOMS). In this proof of concept phantom study, we reconstruct two 2-fold undersampled, simultaneously acquired orthogonal slices.

Evaluation of upper airway neuromuscular reflex and passive collapsibility using real-time multi-slice MRI during CPAP

Weiji Chen¹, Emily Gillett², Sally L. Davidson Ward², Michael C.K. Khoo¹, and Krishna S. Nayak¹

¹University of Southern California, Los Angeles, CA, United States, ²Children's Hospital Los Angeles, Los Angeles, CA, United States

We demonstrate a new imaging test that uses simultaneous multi-slice real-time MRI during continuous positive airway pressure (CPAP) to quantify upper airway neuromuscular reflex and passive collapsibility. Both are measured using cross-sectional area fluctuation during abrupt changes to CPAP. We applied this test to patients with obstructive sleep apnea (OSA) and healthy controls. Subjects with OSA showed 3-5x higher airway area fluctuation compared to healthy volunteers, and this difference was statistically significant ($p < 0.05$). Neuromuscular reflex and area fluctuation varied greatly among the OSA patients, suggesting a potential spectrum of active/physiological and passive/anatomical factors contributing to OSA.

Computer 42

Simultaneous Multi-Slice Radial Phase Contrast MRI

Liyong Chen^{1,2} and David Feinberg^{1,2}

¹Advanced MRI Technologies, LLC, Berkeley, CA, United States, ²Helen Wills Neuroscience Institute, Univ of California, Berkeley, Berkeley, CA, United States

The purpose was to develop and evaluate a novel approach to MR phase imaging of blood flow by combining radial cine phase contrast (radial cine-PC) with simultaneous multi-slice (SMS) technique to measure velocity in several slice planes simultaneously. Comparisons were made between SMS radial and SMS Cartesian 2D cine-PC and the velocity curves measured in cerebral vessels were similar between them. The higher acquisition efficiency of SMS radial cine PC allows for simultaneous cross-sectional hemodynamic quantification and may be useful for medical diagnoses.

Improved CAIPIRINHA for Simultaneous Multislice Imaging Using Total Variation Regularization

Song Gao¹ and Yajun Ma¹

¹Medical Physics Department, Peking University, Beijing, People's Republic of China

The CAIPIRINHA (Controlled Aliasing in Parallel Imaging Results in Higher Acceleration), proposed for simultaneous multislice imaging, combines the multiband excitation and phase cycling techniques to reduce scan time and improve the subsequent imaging reconstruction. The total variation (TV) regularization uses an edge-preserving prior which imposes a relationship between neighboring pixels for image reconstruction. In this work, the TV regularization method is applied to further improve the CAIPIRINHA. In vivo data results demonstrate that the TV regularization is very powerful in suppressing noise, maintaining fine imaging details and reducing aliasing artifacts.

Computer 46

Independent band-specific correction for B₀ and B₁ inhomogeneities in multiband 2D RF pulsesYuxin Hu^{1,2}, Valentina Taviani³, Bruce L. Daniel¹, and Brian A. Hargreaves¹

¹Department of Radiology, Stanford University, Stanford, CA, United States, ²Department of Electrical Engineering, Stanford University, Stanford, CA, United States, ³GE Healthcare, Menlo Park, CA, United States

2D in-plane multiband RF pulses have been developed to offer high-resolution diffusion-weighted imaging (DWI) with minimal distortion. However, B₀ and B₁ inhomogeneities may lead to significant and varying signal loss in different bands, that can in turn result in signal inconsistency between bands. In this work, correction for B₀ and B₁ variations was implemented by independently tuning the RF center frequency and amplitude for each band. Phantom images acquired with corrected pulses were shown to have higher signal amplitude and reduced slab boundary artifacts.

Computer 47

Simultaneous multi-slice (SMS) imaging technique for radial trajectory using inter-slice shifting gradient

Dongchan Kim¹, Jaejin Cho², Kinam Kwon², Byungjai Kim², Yeji Han¹, Jun-Young Chung¹, and HyunWook Park²

¹Gachon University, Incheon, Korea, Republic of, ²Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

SMS imaging techniques utilized phase modulated RF pulses, blipped gradients, or inter-slice shifting gradients to increase the use of sensitivity information of multi-channel coils. In this work, we extended the use of inter-slice shifting gradient based SMS techniques of a Cartesian trajectory to a radial trajectory. We modulated the ratio between inter-slice shifting gradient and readout gradient (*i.e.* view angle) with the cosine function. In addition, we adjusted the direction of shift of each slice by adjusting the offset of cosine function, thereby increase sampling efficiency of a radial trajectory when the imaging objects need an anisotropic field-of-view.

Improved Simultaneous Multislice Pulse Design Directly Constraining Peak RF Amplitude

Sydney N Williams¹, Douglas C Noll², and Jeffrey A Fessler³

¹Biomedical Engineering, University of Michigan, Ann Arbor, MI, United States, ²Blomedical Engineering, University of Michigan, Ann Arbor, MI, United States, ³Electrical Engineering and Computer Science, University of Michigan, Ann Arbor, MI, United States

In this abstract, we propose the design of SMS RF pulses using a new method based on the small-tip angle approximation that directly constrains peak amplitude using a least-square optimization. We compare our proposed method to the equivalent phase-modulated Shinnar-Le Roux (SLR) SMS pulse with optimized phase scheduling for minimal RF power. Our proposed method provides lower simulation error than SLR-based designs at equivalent pulse lengths and same error for shorter pulse lengths that are unrealizable (in the peak amplitude sense) with the SLR-based approach. In experiment we show sharp excitation slice profiles for our SMS designs.

Improved Accelerated Model-based Parameter Quantification with Total-Generalized-Variation Regularization.

Oliver Maier¹, Matthias Schloegl¹, Andreas Lesch¹, Andreas Petrovic¹, Martin Holler², Kristian Bredies², Thomas Pock³, and Rudolf Stollberger¹

¹Institute of Medical Engineering, Graz University of Technology, Graz, Austria, ²Institute of Mathematics and Scientific Computing, University of Graz, Graz, Austria, ³Institute for Computer Graphics and Vision, Graz University of Technology, Graz, Austria

Incorporating TGV-regularization to accelerated model-based parameter-quantification can lead to improved image quality, however, adds non-differentiability to the problem which poses a problem for commonly used first order optimization methods like non-linear Conjugate-Gradient. The proposed method overcomes this limitation by handling the problem within a Gauss-Newton-framework and applying a Primal-Dual-algorithm to solve the inner TGV-regularized problem. Numerical simulations exhibit high agreement to references for four different parameter mapping problems up to 18-fold acceleration. In-vivo results for T1-VFA and T2-MESE models strengthen these findings. The proposed method offers huge acceleration potential for model-based parameter-quantification with similar quantification quality as fully sampled data.

Computer 50

Comparison of Compressed Sensing Accelerated TOF MRA of the Neck with Conventional TOF MRA and Ultrasound in Clinical Cases

Takayuki YAMAMOTO¹, Tomohisa OKADA², Yasutaka FUSHIMI¹, Koji FUJIMOTO³, Akira YAMAMOTO¹, Peter SPEIER⁴, Michaela SCHMIDT⁴, Yutaka NATSUAKI⁵, and Kaori TOGASHI¹

¹Diagnostic Imaging and Nuclear Medicine, Kyoto University, Graduate School of Medicine, Kyoto, Japan, ²Human Brain Research Center, Kyoto University, Graduate School of Medicine, Kyoto, Japan, ³Center for Advanced Imaging Innovation and Research (CAI2R) and Bernard and Irene Schwartz Center of Biomedical Imaging, New York University School of Medicine, New York, NY, United States, ⁴Siemens Healthcare GmbH, ⁵Siemens Medical Solutions USA, Inc.

Compressed sensing (CS) can accelerate time-of-flight magnetic resonance angiography (TOF MRA) of the neck. The whole length of carotid arteries from the aortic arch to the skull base was scanned in 2 minutes with an acceleration factor of 7.5. Iterative reconstruction that exploits regularization in 3 spatial directions required less than 3 minutes on a GPU. The degree of stenosis at carotid bifurcation for 22 patients was subjectively evaluated on maximum intensity projection images. Results of CS accelerated TOF MRA and conventional TOF MRA were compared with stenotic rates measured by ultrasound, and showed an excellent correlation.

Self-Calibrated Non-Cartesian Multi-shot Diffusion Imaging

Merry Mani¹, Arnaud Guidon², Baolian Yang², Vincent Magnotta¹, and Mathews Jacob³

¹Radiology, University of Iowa, Iowa City, IA, United States, ²GE Healthcare, ³Electrical and Computer Engineering, University of Iowa, Iowa City, IA, United States

Non-Cartesian multi-shot sequences (e.g. spiral) offer several benefits over Cartesian counterparts in the context of high spatial resolution diffusion weighted imaging (DWI), including reduced B_0 & T_2^* artifacts, as well as improved SNR resulting from lower TE. However, their main drawback of the above scheme is the sensitivity of the multi-shot imaging to motion artifacts. To achieve motion compensation, the multi-shot reconstruction methods rely on a phase-calibration procedure, during which an estimate of motion induced phase map is computed. Not only is the phase-calibration step time consuming, it also involves heavy optimization of parameters. The main focus of this work is to develop a phase calibration-free motion-compensated reconstruction for multi-shot non-Cartesian diffusion imaging.

Computer 53

Low Rank Alternating Direction Method of Multipliers Reconstruction for MR Fingerprinting

Jakob Assländer^{1,2,3}, Martijn A Cloos^{1,2}, Florian Knoll^{1,2}, Daniel K Sodickson^{1,2}, Jürgen Hennig³, and Riccardo Lattanzi^{1,2}

¹Dept. of Radiology - Bernard and Irene Schwartz Center for Biomedical Imaging, New York University School of Medicine, New York, NY, United States, ²Dept. of Radiology - Center for Advanced Imaging Innovation and Research, New York University School of Medicine, New York, NY, United States, ³Dept. of Radiology - Medical Physics, University Medical Center Freiburg, Freiburg, Germany

The proposed reconstruction framework for MR-Fingerprinting (MRF) combines a low rank approximation of the signal's temporal evolution with the alternating direction method of multipliers. This general framework allows for incorporating parallel imaging and compressed sensing. The low rank approximation of the signal's temporal evolution reduces the number of fast Fourier transformations significantly and addresses the non-convexity of the MRF-reconstruction problem. Overall, the convergence is improved and undersampling artifacts are reduced, resulting in a fast, robust and flexible reconstruction framework.

Compressed Sensing 3D GRASE with Group-Sparse Reconstruction for Brain Myelin Water Imaging

Henry Szu-Meng Chen¹, Emil Ljungberg², Alex L MacKay^{1,3,4}, and Piotr Kozlowski^{3,5}

¹Physics and Astronomy, University of British Columbia, Vancouver, BC, Canada, ²Medicine, University of British Columbia, Vancouver, BC, Canada, ³Radiology, University of British Columbia, Vancouver, BC, Canada, ⁴UBC MRI Research Centre, Vancouver, BC, Canada, ⁵UBC MRI Research Centre, Vancouver, BC, Canada

Myelin water fraction (MWF), which reflects myelin content, can be derived from multiple T2 weighted images. In this study, compressed sensing was used to accelerate 3D GRASE myelin water imaging in simulated experiments using a Cartesian undersampling scheme. Group-sparse reconstruction that exploits the correlation between the echoes, and different echo sampling schemes, were tested. Group-sparse reconstruction was found to improve the overall data quality, and identical phase encode undersampling for each echo was found to improve MWF map quality. Using both, MWF map quality remained usable for up to 4x acceleration.

3862

Computer 57

Compressive T2 Mapping with Non-Local Clustering and Subspace Constraints

Sagar Mandava¹, Mahesh B Keerthivasan¹, Maria I Altbach², and Ali Bilgin^{1,2,3}

¹Electrical and Computer Engineering, University of Arizona, Tucson, AZ, United States, ²Medical Imaging, University of Arizona, Tucson, AZ, United States, ³Biomedical Engineering, University of Arizona, Tucson, AZ, United States

Subspace constrained T2 mapping uses PCA to reconstruct a few principal components instead of all the echo train images before T2 fitting. The temporal (contrast) subspace in these methods is estimated either from acquired training data or via training curves from a signal model. Typically, a single global PC basis is used for all the contrast signals. In this work we present a T2 mapping method based on non-local clustering of signal relaxation curves and tailor the PC bases for the curves in each cluster and compare it with the global PC basis approach.

True Temporal Resolution TWIST Imaging using Annihilating Filter-based Low-rank wrap around Hankel Matrix

Eun Ju Cha¹, Kyong Hwan Jin², Eung Yeop Kim³, and Jong Chul Ye¹¹KAIST, Daejeon, Korea, Republic of, ²EPFL, Lausanne, Switzerland, ³Gachon University Gil Medical Center, Incheon, Korea, Republic of

Temporal resolution is an important factor in dynamic enhanced contrast (DCE) MRI. Time-resolved angiography with interleaved stochastic trajectories (TWIST) has been widely used due to its improved temporal and spatial resolution. However, the temporal resolution of TWIST imaging is not a true one because of the view sharing. To provide more improved temporal resolution, we proposed a novel reconstruction algorithm based annihilating filter-based low rank Hankel matrix approach (ALPHA) which exploits the fundamental duality between sparsity in transform domain and low-rankness of Hankel matrix constructed using k-space data. Experimental result using in-vivo data showed the significantly improved temporal resolution than the conventional reconstruction.

Robust GRASP: A novel approach using the Huber norm in projection space for robust data consistency in undersampled radial MRI

Marcelo V. W. Zibetti¹, Rebecca Ramb², Li Feng², Ricardo Otazo², Leon Axel², and Gabor T. Herman³¹NYU/CUNY/UTFPR, New York, NY, United States, ²Radiology, NYU School of Medicine, New York, NY, United States, ³Computer Science, CUNY, New York, NY, United States

Robust data consistency using the Huber norm is proposed for compressed sensing radial MRI to reduce artifacts associated with outliers in the acquired data that cannot be removed by the sparse reconstruction. System imperfections such as chemical shift can introduce this type of large data distortions, or outliers. The quadratic shape of the usually employed Euclidean norm for data consistency is very sensitive to very large errors. In the proposed method, named RObust Golden-angle Radial Sparse Parallel MRI (ROGRASP), the Huber norm enables large errors to remain in the data discrepancy, not transferring them to the reconstructed image. In vivo acquisitions with outlier-contaminated data illustrate this improvement in quality for free-breathing cardiac MRI.

Joint Reconstruction of Multi-Contrast Images: Compressive Sensing Reconstruction using both Joint and Individual Regularization Functions

Emre Kopanoglu¹, Alper Gungor¹, Toygan Kilic^{2,3}, Emine Ulku Saritas^{2,3}, Tolga Cukur^{2,3}, and H. Emre Guven¹

¹Aselsan Research Center, Ankara, Turkey, ²Electrical and Electronics Engineering, Bilkent University, Turkey, ³National Magnetic Resonance Research Center (UMRAM), Bilkent University, Turkey

In many clinical settings, multi-contrast images of a patient are acquired to maximize complementary information. With the underlying anatomy being the same, the mutual information in multi-contrast data can be exploited to improve image reconstruction, especially in accelerated acquisition schemes such as Compressive Sensing (CS). This study proposes a CS-reconstruction algorithm that uses four regularization functions; joint L1-sparsity and TV-regularization terms to exploit the mutual information, and individual L1-sparsity and TV-regularization terms to recover unique features in each image. The proposed method is shown to be robust against leakage-of-features across contrasts, and is demonstrated using simulations and in-vivo experiments.

Self-Calibrating Multi-Coil Phase Combination Using The Localized Singular Value Decomposition
Jong Bum Son¹

¹Department of Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston, TX, United States

MRI can encode clinically important information in the image-phase, thus has great potentials to extend its capability for clinical applications. However, if phase references are not available, the multi-coil phase combination using the weighted average suffers from dominant signal losses coming from phase cancellations due to uncompensated coil-dependent phase offsets.

In this work, we developed a self-calibrating multi-coil phase combining method which does not require any additional scans for phase references. When applied to a single-point Dixon imaging, we verified the proposed method could successfully estimate the global phase-map with the minimal signal loss only using a single-scan image.

OEDIPUS: Towards optimal deterministic k-space sampling for sparsity-constrained MRI
Justin P. Haldar¹ and Daeun Kim¹

¹Electrical Engineering, University of Southern California, Los Angeles, CA, United States

We propose a novel approach to designing optimal k-space sampling patterns for sparsity-constrained MRI. The new approach, called OEDIPUS (Oracle-based Experiment Design for Imaging Parsimoniously Under Sparsity constraints), is inspired by insights and methods from estimation theory and the statistical design of experiments. Specifically, OEDIPUS combines the oracle-based Cramér-Rao bound for sparsity-constrained reconstruction with sequential greedy algorithms for observation selection. We demonstrate that OEDIPUS can be used to deterministically and automatically generate k-space sampling patterns that are tailored to specific hardware and application contexts, and which lead to better reconstruction performance relative to conventional sampling approaches for sparse MRI.

GenSeT: Reconstruction of k-space under-sampled DCE-MRI data using high-order generalized series and temporal constraint
Hien Minh Nguyen¹, Yuan Le², and Wei Huang³

¹Electrical Engineering & Information Technology, Vietnamese-German University, Binh Duong New City, Vietnam, ²Department of Radiology, Mayo Clinic Arizona, Scottsdale, AZ, United States, ³Advanced Imaging Research Center, Oregon Health & Science University, Portland, OR, United States

A novel reconstruction method exploiting high-order generalized series and temporal sparsity constraint has been presented for sparsely-sampled DCE-MRI. The method uses a static reference to model high-resolution anatomical structures while extrapolating the missing k-space and imposing the sparsity of the time frame difference. Our initial experience with human breast DCE-MRI data shows that the proposed GenSeT method yields more accurate spatiotemporal dynamics and PK analysis than the conventional zero-filling and TWIST reconstruction methods. Further validation of the method as a useful reconstruction approach for sparsely-sampled DCE-MRI is warranted in a larger cohort and with data from different organs.

Correlating ZTE MRI signal to bone density to derive a patient-specific attenuation correction map in brain PET/MR

Maya Khalifé¹, Brice Fernandez², Olivier Jaubert¹, Michael Soussan³, Irène Buvat³, Vincent Brulon³, and Claude Comtat³

¹Brain and Spine Institute (ICM), Hôpital de la Pitié-Salpêtrière, Paris, France, ²Applications and Workflow, GE Healthcare, Orsay, France, ³Laboratoire d'Imagerie Moléculaire In Vivo (IMIV), Commissariat à l'Energie Atomique et aux Energies Alternatives (CEA), Orsay, France

Attenuation correction (AC) is needed for an accurate PET image quantification in brain PET/MR. Regular MRI cannot distinguish between different tissue types based on electron density, thus, Zero Echo Time (ZTE) has been used to segment bone, air and soft tissue. Furthermore, a correlation has been established between histogram normalized ZTE intensity and measured CT density in Hounsfield Unit (HU) in bone on a CT-MR database of 16 patients. The patient-specific AC map generated by combining ZTE-based segmentation and linear scaling of normalized ZTE signal into HU showed to be a good substitute of the measured CT-AC map in brain PET/MR.

Computer 74

Fully-Integrated 3D High-Resolution Multi-Contrast Abdominal PET-MR with High Scan Efficiency

Christoph Kolbitsch^{1,2}, Radhouene Neji³, Matthias Fenchel⁴, Andrew Mallia², Paul Marsden², and Tobias Schaeffter^{1,2}

¹Physikalisch-Technische Bundesanstalt (PTB), Braunschweig and Berlin, Germany, ²Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, ³MR Research Collaborations, Siemens Healthcare, Frimley, United Kingdom, ⁴MR Oncology Application Development, Siemens Healthcare, Erlangen, Germany

Abdominal PET-MR scans commonly combine free-breathing PET with breathhold or respiratory-triggered MR scans (T1/T2-weighted). This ensures high MR image quality but can lead to PET images impaired by motion blurring. Furthermore, PET can suffer from artefacts close to tissue-lung interfaces due to misalignment of breathhold MR-based attenuation correction (AC) information used for free-breathing PET. Here we present a free-breathing MR-technique which yields motion-compensated 3D T1-weighted and T2-weighted MR images. Respiratory-resolved AC maps and motion compensation improved uptake values ($125\pm 131\%$) and resolution ($22\pm 16\%$). Respiratory motion information is obtained with an accuracy of 1.3 ± 0.1 mm without an increase in scan time.

Computer 75

Penta-contrast imaging: a Novel Pulse Sequence for Simultaneous Acquisition of Proton Density, T₁, T₂, T₂* and FLAIR images

Jinhee Jeong¹, Yoonho Nam², and Jongho Lee¹

¹Department of electrical and computer engineering, Seoul National University, Seoul, Korea, Republic of, ²Department of Radiology, Seoul Saint Mary's Hospital

A penta-contrast imaging sequence that generates proton density (PD), T₁, T₂, T₂* and FLAIR images in a single scan is developed. Compared to conventional imaging sequences, the scan time is reduced by 50 %. Additionally, the new method generates T₁ and T₂ maps.

3882

Computer 76

Magnetic Resonance Fingerprinting for T₁ and T₂* quantification with Cartesian readout

Benedikt Rieger¹, Fabian Zimmer¹, Jascha Zapp¹, Sebastian Weingärtner^{1,2,3}, and Lothar R. Schad¹

¹Computer Assisted Clinical Medicine, Heidelberg University, Mannheim, Germany, ²Electrical and Computer Engineering, University of Minnesota, ³Center for Magnetic Resonance Research, University of Minnesota

Magnetic resonance fingerprinting (MRF) has shown exceptional promise for simultaneous quantification of T₁ and T₂, based on numerous spiral readouts. We propose an implementation of the MRF paradigm for quantitative imaging using spoiled echo-planar imaging (EPI) with Cartesian readout for simultaneous assessment of T₁ and T₂* within 10s. Joint T₁ and T₂* parameter-maps acquired in phantoms with the proposed MRF method are in good agreement with reference measurements and demonstrate high quality in-vivo. This approach offers a rapid supplement to the non-Cartesian MRF portfolio, with potentially increased usability and robustness.

Computer 77

Validation of an Image Derived Input Function Method for PET/MR Brain Scans

Mohammad Mehdi Khalighi¹, Mathias Engström², Mark Lubberink³, and Greg Zaharchuk⁴

¹Applied Science Lab, GE Healthcare, Menlo Park, CA, United States, ²Applied Science Lab, GE Healthcare, Uppsala, Sweden, ³Nuclear Medicine & PET, Department of Surgical Sciences, Uppsala University, Uppsala, Sweden, ⁴Radiology Department, Stanford University, Palo Alto, CA, United States

Accurate measurement of the arterial input function (AIF) is essential in quantitative analysis of cerebral blood flow (CBF) using ¹⁵O-water PET imaging. The time-of-flight enabled SIGNA PET/MR scanner (GE Healthcare, Waukesha, WI, USA) provides high quality PET images, which can be used for non-invasive Image Derived Input Function (IDIF) estimation. AIF was measured using a proposed IDIF method on 4 patients and the results were compared with the gold standard, arterial blood sampling. The comparison shows excellent correspondence between IDIF and blood sampling, thus validating the IDIF method.

Computer 78

Whole-body morphological and functional atlas using an integrated PET-MRI system and fat-water registration

Simon Ekström¹, Therese Sjöholm¹, Filip Malmberg^{1,2}, Lars Lind³, Håkan Ahlström^{1,4}, Joel Kullberg^{1,4}, and Robin Strand^{1,2}

¹Division of Radiology, Department of Surgical Sciences, Uppsala University, Uppsala, Sweden, ²Centre for Image Analysis, Uppsala University, Uppsala, Sweden, ³Department of Medical Sciences, Uppsala University, Uppsala, Sweden, ⁴Antaros Medical, Sweden

Today, when whole-body PET-MRI datasets are analyzed, the data is typically reduced to a few a priori specified measurements. New tools are developed in an attempt to utilize the full potential of large whole-body datasets. The purpose of this work was to build a preliminary whole-body atlas, containing both morphological (fat and water MR) and functional (FDG-PET) information on normality. An atlas was built out of 30 subjects using an integrated PET-MRI system together with an efficient registration method for fat-water MR images. The atlas was used in a proof-of-concept anomaly detection in FDG-PET using a pointwise t-test, which successfully detected anomalies in our test subject.

Rapid Dual Echo UTE MR-Based Attenuation Correction

Hyungseok Jang¹ and Alan B McMillan¹

¹Department of Radiology, University of Wisconsin, Madison, WI, United States

Recently, ultrashort TE imaging based MR-based attenuation correction (MRAC) has been proposed in literature to overcome the intrinsic difficulty in MRI to resolve bone contrast and hence enable more reliable estimation of attenuation map. However, the long acquisition time required for UTE imaging still remains challenging. In this study, we propose a novel, rapid dual echo method for UTE based MRAC, which allows segmentation of bone, air, fat, and water with high spatial resolution (1mm³) in a single scan with extremely short scan time (35sec).

3887

Computer 81

Atlas-based generation of synthesized transmission images for brain PETMR attenuation correction using MPRAGE

Karl D Spuhler¹, Nandita Joshi², Christine DeLorenzo^{1,3}, Ramin Parsey³, and Chuan Huang^{1,3,4}

¹Biomedical Engineering, Stony Brook University, Stony Brook, NY, United States, ²Electrical and Computer Engineering, Stony Brook University, Stony Brook, NY, United States, ³Psychiatry, Stony Brook Medicine, Stony Brook, NY, United States, ⁴Radiology, Stony Brook Medicine, Stony Brook, NY, United States

Attenuation correction remains a challenge in simultaneous PETMR, as MR signal is not directly related to attenuation. This is particularly problematic in PETMR studies of the brain, where accurate radiotracer quantification is extremely important. Here, we present a method for generating individual-specific transmission data for attenuation correction from an input MPRAGE MR volume. The method uses an atlas of matched MPRAGE and transmission images in order to achieve this. Our method does not add to scan time, as do common MR-based methods, and directly yields attenuation data for PET energies, unlike CT-based methods.

3888

Computer 82

Intensity inhomogeneity correction of whole body fat-water images using fat and water fraction information on a 3T PET/MR scanner

Therese Sjöholm¹, Simon Ekström¹, Filip Malmberg^{1,2}, Robin Strand^{1,2}, Magnus Johansson¹, Lars Lind³, Mathias Engström⁴, Håkan Ahlström^{1,5}, and Joel Kullberg^{1,5}

¹Radiology, Uppsala University, Uppsala, Sweden, ²Centre for Image Analysis, Uppsala University, Uppsala, Sweden, ³Medical Sciences, Uppsala University, Uppsala, Sweden, ⁴Applied Science Laboratory, GE Healthcare, Uppsala, Sweden, ⁵Antaros Medical, Mölndal, Sweden

We describe and evaluate a method for intensity non-uniformity correction of whole-body fat-water MR data acquired with both surface and body coils on a 3T PET/MRI system. The proposed method consists of two steps. Abrupt station intensity changes are first suppressed, followed by correction of smooth intensity changes using fat and water fraction information. Visual and quantitative evaluations of 42 corrected fat-water datasets show that the method gives improved adipose and lean tissue uniformity for both surface and body coil acquisitions. This renders the data suitable for continued analysis in a whole-body imaging framework.

Multiple Instantaneous Switchable Scans interleaving T2W and DWI for Prostate Biparametric MRI

Wei WANG¹, Xiubo QIN¹, Juan WEI², and Xiaoying WANG¹

¹Peking University First Hospital, Beijing, People's Republic of China, ²Philips Research China, Shanghai, People's Republic of China

Multiple Instantaneous Switchable Scans (MISS) is a type of interleaved scan method. In our study of prostate MRI, we combined the 3D-T2W and DWI by MISS into one scan, both of which are essential sequences for PIRADS v2. The combined sequences improved the scan efficiency (6min to 4min30s). The image quality and lesion display of MISS is similar to conventional T2W and DWI. The 3D-T2W in MISS showed better performance of seminal vesicles and lesion contrast and allowed for interactive multiplanar reformation.

PET-MRI in hepatocellular carcinoma: Correlation of DCE-MRI perfusion quantification using shutter-speed model with FDG uptake

Stefanie Hectors¹, Mathilde Wagner¹, Cecilia Besa¹, Wei Huang², and Bachir Taouli¹

¹Translational and Molecular Imaging Institute, Icahn School of Medicine at Mount Sinai, New York, NY, United States, ²Advanced Imaging Research Center, Oregon Health & Science University, Portland, OR, United States

Shutter-speed modeling (SSM) of DCE-MRI data allows for estimation of the mean intracellular water molecular lifetime (τ_i), which has been suggested to be associated with tissue metabolic activity. In this study, we assessed the correlation between SSM DCE-MRI parameters and FDG-PET uptake in hepatocellular carcinoma (HCC) lesions. While K^{trans} did show a significant negative correlation with the standardized uptake value (SUV) in the HCC lesions, τ_i was not significantly associated with FDG uptake. Our preliminary findings suggest that τ_i may not be associated with the up-stream tumor glucose metabolism as measured by FDG-PET.

Computer 88

[Water content, diffusion measures \(DTI/DKI\) and FET-PET in brain tumours: investigating similarities and differences](#)
Ana-Maria Oros-Peusquens^{*1}, Ricardo Loucao^{*1,2}, Hugo Ferreira², Karl-Josef Langen¹, and Nadim Jon Shah¹

¹INM-4, Research Centre Jülich, Jülich, Germany, ²Instituto de Biofísica e Engenharia Biomédica, Sciences Faculty, University of Lisbon, Lisbon, Portugal

Water content, diffusion measures and FET-PET measured simultaneously on a hybrid 3T scanner in 40 brain tumour patients were investigated. Despite reasonable expectations of finding some microscopic-structure-driven correlations between these parameters, compared here for the first time, low correlations were found in healthy tissue. Interestingly, the correlation between water content and diffusion indices -while still rather low - increased in tumour tissue. Importantly, this implies that each parameter reflects different aspects and thus their combination should be more powerful for oncology than using single parameters

3895

Computer 89

[In Vivo T1 and T2 Mapping using Single-Shot EPI Fingerprinting](#)
Cory Robert Wyatt^{1,2}, John Grinstead³, and Alexander Guimaraes¹

¹Radiology, Oregon Health and Science University, Portland, OR, United States, ²Advanced Imaging Research Center, Oregon Health and Science University, Portland, OR, United States, ³Siemens Healthcare, Portland, OR, United States

MR fingerprinting (MRF) studies have been performed using heavily undersampled spiral acquisitions, which constantly rotate and use uncorrelated aliasing to fit quantitative T1 and T2 maps. On top of the usual spiral sensitivity to off-resonance, the undersampling used in MRF requires a slowly varying signal evolution to "see through" the aliasing artifacts. Echo-planar imaging (EPI) would avoid these aliasing issues while still having a short measurement time due to a single-shot acquisition and parallel imaging acceleration. In this study, a single-shot EPI sequence is combined with fingerprinting techniques to obtain T1 and T2 maps similar to those from spiral fingerprinting.

3896

Computer 90

[Fast Magnetic Resonance Fingerprinting of Mouse Brain Using a Spiral Trajectory](#)

Yuning Gu¹, Charlie Wang¹, Christian Anderson¹, Yuchi Liu¹, Dan Ma¹, Yun Jiang¹, Mark A. Griswold^{1,2}, Chris A. Flask^{1,2,3}, and Xin Yu^{1,2,4}

In this study we developed spiral-based MRF sequences for fast T₁ and T₂ mapping of mouse brain at 7T. A variable density spiral trajectory that fully sampled the inner 10×10 k-space with 4 interleaves enabled up to 6-fold acceleration for both MRF-bSSFP and MRF-FISP sequences, corresponding to a 3-min scan to acquire 1024 time frames for simultaneous T₁ and T₂ mapping.

3897

Computer 91

[PET-MR Motion Correction of Entire Listmode Data Sets Using Pilot Tone Navigation](#)

Thomas Vahle¹, David Stephen Rigie², Ryan Brown², Tiejun Zhao, Li Feng², Matthias Fenchel¹, Peter Speier¹, and Fernando Boada²

¹Siemens Healthcare GmbH, Erlangen, Germany, ²Radiology, Center for Advanced Imaging Innovation and Research (CAI2R), New York University Langone Medical Center, New York, NY

The introduction of simultaneous PET-MR provides new opportunities for motion tracking and correction during PET imaging. The ideal clinical workflow for a PET-MR exam would allow for PET data to be continuously acquired alongside any desired MR sequences and to reconstruct a motion-corrected PET image utilizing the entire dataset. In this work we combine a surface coil driven by an external signal generator with an MR motion model to navigate PET data during an entire PET-MR exam. We demonstrate the approach on one human subject that underwent a PET-MR exam.

Dual-echo UTE MR sequences are widely used to estimate PET attenuation coefficients in simultaneous PET/MR imaging. However, due to susceptibility artefacts, air cavities in the head together with brain tissues and bones, can be misclassified, especially around air-tissue interface regions. In this work, we propose an SPM-based air and background segmentation method to improve the PET attenuation correction for simultaneous PET/MR imaging of the human brain. We compare air segmentation methods for more accurate air classification using an *in-vivo* MR-PET dataset and demonstrate improved PET image reconstruction accuracy.

3899

Computer 93

Impact of MR-based Motion Correction on clinical PET/MR data of patients with thoracic pathologies

Marcel Gratz^{1,2}, Verena Ruhlmann³, Lale Umutlu⁴, Matthias Fenchel⁵, and Harald H. Quick^{1,2}

¹Erwin L. Hahn Institute, University Duisburg-Essen, Essen, Germany, ²High Field and Hybrid MR Imaging, University Hospital Essen, Essen, Germany, ³Department of Nuclear Medicine, University Hospital Essen, Essen, Germany, ⁴Department of Diagnostic and Interventional Radiology and Neuroradiology, University Hospital Essen, Essen, Germany, ⁵Siemens Healthcare GmbH, Erlangen, Germany

A new PET/MR method for MR-based motion correction of PET data was set up and evaluated in a clinical study to assess the potential gain of significance and visibility of lesions in the thorax for a free-breathing patient. The new method (MoCo) was applied to 20 patients and compared to reconstructions of a single respiratory state (gated) and the total non-corrected (static) dataset. Having a comparably high statistical confidence like the static PET imagery, the motion-corrected reconstruction shows superior image quality with sharper depiction of moving lesions and thus may facilitate the diagnosis of thoracic pathologies in routine PET/MR applications.

MR-Based Respiratory and Cardiac Motion Corrected 18F-FDG-PET/MR in Cardiac Sarcoidosis

Philip M Robson¹, Nicolas A Karakatsanis¹, Maria Giovanna Trivieri¹, Ronan Abgral², Marc R Dweck³, Jason C Kovacic⁴, and Zahi A Fayad¹

¹Translational and Molecular Imaging Institute, icahn school of medicine at mount sinai, New York, NY, United States, ²Department of Nuclear Medicine, European University of Brittany, ³British Heart Foundation/University Centre for Cardiovascular Science, University of Edinburgh, ⁴Cardiovascular Institute, Icahn School of Medicine at Mount Sinai

A major advantage of hybrid PET/MR systems is the radiation-free high spatial and temporal resolution of cardiac MR imaging that can be used to estimate respiratory and cardiac motion present during PET data acquisition. This information can be incorporated into algorithms to correct for the effects of motion in the PET data to reduce blurring and increase target-to-background ratios of PET hotspots. In this work, we demonstrate a method for respiratory and cardiac motion correction in patients with cardiac sarcoidosis.

3901

Computer 95

Automatic Extraction of Cardiac and Respiratory Motion via Self-Refocused Rosette Navigators and Independent Component Analysis

David Rigie¹, Thomas Vahle², Tiejun Zhao³, Klaus Schäfers⁴, Björn Czekalla⁴, Lynn Frohwein⁴, and Fernando Boada¹

¹Radiology, Center for Advanced Imaging Innovation and Research (CAI2R), New York University Langone Medical Center, New York, NY, United States, ²Siemens Healthcare GmbH, Erlangen, Germany, ³Siemens Healthcare, New York, NY, ⁴European Institute for Molecular Imaging, University of Münster, Münster, Germany

Due to the recent availability of simultaneous PET-MR, there has been much interest in MR-based motion correction for PET imaging. A key component of any such scheme is a mechanism for tracking respiratory and cardiac motion phases throughout the entire exam. In this work, we present a robust, automated approach whereby respiratory and cardiac motion information is jointly encoded with rosette navigators and decoded via independent component analysis (ICA). This approach obviates the need for any external motion tracking devices (e.g. bellows or ECG) and requires just a contrast-neutral, self-refocused navigator echo (≈ 2 ms) per repetition time and so may be easily incorporated into many clinical sequences.

Limitations of NMR Field Cameras for B₀ Field MonitoringPaul Chang^{1,2}, Sahar Nassirpour^{1,2}, and Anke Henning^{1,3}

¹MPI for Biological Cybernetics, Tuebingen, Germany, ²IMPRS for Cognitive and Systems Neuroscience, Eberhard University of Tuebingen, Tuebingen, Germany, ³Institute of Physics, Ernst-Moritz-Arndt University Greifswald, Greifswald, Germany

We compare the fields measured by a field camera to the fields obtained from B₀ mapping at 9.4T. The B₀ maps have higher spatial resolution and are therefore taken as a benchmark. We analyse the loss of spatial fidelity due to the lower spatial samples of the field camera and compare two different field probe position calibration and optimisation methods that would help alleviate the problem of discrepancies between field monitoring and field mapping.

3903

Computer 98

Estimating B₀ inhomogeneities with projection FID navigator readoutsAlexander Loktyushin^{1,2}, Philipp Ehses^{1,3}, Bernhard Schölkopf², and Klaus Scheffler^{1,3}

¹High-field MRI, Max Planck Institute for Biological Cybernetics, Tübingen, Germany, ²Empirical Inference, Max Planck Institute for Intelligent Systems, Tübingen, Germany, ³Biomedical Magnetic Resonance, University of Tübingen, Tübingen, Germany

B₀ field inhomogeneities can negatively impact the image acquisition process, cause artifacts such as ghosting and blurring and introduce physiological noise in fMRI time series. It is common to address the static inhomogeneity components by using shim coils. Physiological motion during the acquisition can lead to temporal variations in the field configuration. Dynamic shimming necessitates fast, real-time estimation of B₀ distortions. In this work, we augment projection-encoded FID readouts with a simple projection-based spatial encoding and train a neural network to learn the mapping from projection FIDs to field maps, which we obtain using a double-echo EPI sequence.

3904

Computer 99

High-Dynamic-Range High-SNR B₁⁺ Mapping Using Multiple Cyclic MR SignalsMéline Bouldi¹, Tatiana Nemetan^{2,3}, and Jan M Warkning^{2,3}

¹Département Ingénierie des Equipements de Travail, INRS, Nancy, France, ²U1216, Inserm, Grenoble, France, ³Grenoble Institut des Neurosciences, Université Grenoble Alpes, Grenoble, France

A method is presented to perform B₁⁺-mapping simultaneously with high dynamic range and high SNR by optimally combining data from acquisitions with different acquisition parameters. Reconstruction of the B₁⁺-maps is performed using dictionary matching methods. This approach is applicable to various B₁⁺-mapping sequences. Examples based on the AFI sequence are shown in both numeric simulations and a phantom experiment in the presence of a severe B₁⁺ hot-spot. The performance of the proposed methods largely exceeds that of classic AFI sequences, simultaneously matching low-flip-angle acquisitions in dynamic range and high-flip-angle acquisitions in SNR, at identical acquisition times.

Assessment of Geometric Distortion in EPI with a SPAMM Tagged Acquisition

Ken-Pin Hwang¹, Joseph Meier¹, Joshua Yung¹, and R. Jason Stafford¹

¹Department of Imaging Physics, The University of Texas M.D. Anderson Cancer Center, Houston, TX, United States

Diffusion weighted EPI is susceptible to distortions due to multiple causes, and the amount of distortion is dependent on many interacting factors. Hence no good methodology currently exists for assessing and characterizing these distortions. In this work an EPI sequence is modified to include Spatial Modulation of Magnetization (SPAMM), a preparation technique that produces tagged grid lines in the imaged volume. This sequence is acquired to measure induced distortion in several phantoms in different coils with different sequence options, measuring distortion as it varies with parallel imaging acceleration, diffusion weighting direction, and susceptibility of various phantom materials.

3906

Computer 101

Encoding of Inductively Measured k-Space Trajectories in MR Raw Data

Jan Ole Pedersen^{1,2}, Christian G. Hanson, Rong Xue³, and Lars G. Hanson^{1,2}

¹Centre for Magnetic Resonance, DTU Elektro, Technical University of Denmark, Kgs Lyngby, Denmark, ²Danish Research Centre for Magnetic Resonance, Centre for Functional and Diagnostic Imaging and Research, Copenhagen University Hospital, Hvidovre, Denmark, ³Institute of Biophysics, Chinese Academy of Sciences, State Key Laboratory of Brain and Cognitive Science, Beijing, People's Republic of China

For reconstruction of MRI from raw data, the k-space trajectory is needed. We propose to measure this simultaneously with the MRI signal using novel hardware and the scanner itself. As a first step, we demonstrate real-time processing of a gradient pickup coil voltage during scanning, modulation of this signal to a frequency within the MR acquisition bandwidth, and signal extraction from MR raw data. This principle is applied to measure k-space trajectories inductively and perform image reconstruction based on this. The resulting images have comparable quality to images reconstructed using nominal k-space trajectories. The method can potentially provide generic image reconstruction with limited hardware, even for challenging and dynamically updated gradient schemes.

Computer 102

On the deviation of actual isocenter slice position in magnetic resonance imaging

Julian Emmerich¹, Sina Straub¹, and Frederik Bernd Laun^{1,2}

¹Medical Physics in Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany, ²Institute of Radiology, University Hospital Erlangen, Erlangen, Germany

Due to imperfect laser positioning, actual isocenter slice positions can deviate from manufacturer indication. Using MRI as tool for dose planning in MR guided radiation therapy, the geometric correct position of MR-slices is an essential quality parameter that can affect dose calculation and definition of the planning target volume (PTV). To evaluate the magnitude of the deviation of the actual slice position from the true isocenter of the scanner, a phantom study was performed. Scanner-dependent deviations in isocenter slice position occurred in the range of 1 mm - 5 mm.

Robust B1 Mapping with Phase-sensitive Orthogonal Excitation RF Pulses

Jie Wen¹, Alexander Sukstansky¹, and Dmitriy Yablonskiy¹

¹Radiology, Washington University in St. Louis, St. Louis, MO, United States

Accurate B1 measurement is important in many MR related applications. In this study, we proposed and optimized a phase-sensitive approach for B1 mapping that relies on a multi-gradient-echo sequence with two successive orthogonal RF pulses used for signal excitation. We also proposed optimized methods for combining multi-channel data, allowing for optimal parameters' estimation. The method was validated on phantoms and tested on human participants. By applying this method on SMART (Simultaneous Multi-Angular Relaxometry of Tissue) MRI, we reaffirmed the importance of the B1 correction for quantifying biological tissues relaxation and magnetization transfer parameters.

Implementation of a Gradient Pre-emphasis Based on the Gradient Impulse Response Function

Manuel Stich¹, Tobias Wech¹, Anne Slawig¹, Ralf Ringler², Andrew Dewdney³, Andreas Greiser³, Gudrun Ruyters³, Thorsten Bley¹, and Herbert Köstler¹

¹Department of Diagnostic and Interventional Radiology, University of Würzburg, Würzburg, Germany, ²X-Ray & Molecular Imaging Lab, Technical University Amberg-Weiden, Weiden, Germany, ³Siemens, Erlangen, Germany

The gradient impulse response function (GIRF) completely characterizes the gradient system as a linear and time-invariant (LTI) system, and has recently been used to correct for distorted k-space trajectories in image reconstruction. We now report on the implementation of a GIRF-based pre-emphasis, which is resulting in gradient waveforms already matching the desired k-space trajectory and rendering post-corrections obsolete. The method was successfully tested in a sequence with modulated phase-encoding gradients, as for example used in Wave-CAIPI.

Spatiotemporal Magnetic Field Monitoring with Hall Effect Sensors

Koray Ertan¹, Soheil Taraghinia¹, Ayca Takmaz², Secil Eda Dogan², Safa Ozdemir¹, and Ergin Atalar¹

¹National Magnetic Resonance Research Center (UMRAM), Bilkent University, Ankara, Turkey, ²Electrical and Electronics Engineering, Bilkent University, Ankara, Turkey

Hall effect sensors can be used to monitor the spatiotemporal field dynamics. However, measurement of the z component of the magnetic field (Bz) requires very large dynamic range for the Hall effect sensors due to superposition of encoding fields with main magnetic field (B0). Instead, we propose to measure the transverse components of the magnetic field in several spatial positions to reconstruct spatiotemporal dependency of Bz and we have demonstrated reconstruction of the first order spherical harmonic field distributions.

Free breathing Motion-Robust Cardiac B1+ mapping at 3.0T based on DREAM

Teresa Rincón^{1,2}, Anne Menini², Ana Beatriz Solana², André Fischer^{2,3}, Guido Kudielka², and Wei Sun⁴

¹Technische Universität München, Munich, Germany, ²GE Global Research, Munich, Germany, ³Cardiac Center of Excellence, GE Healthcare, Munich, Germany, ⁴GE Healthcare, Waukesha, WI, United States

Radiofrequency (RF) field inhomogeneities affect image quality while performing body and cardiac imaging especially at high field strengths. RF shimming and quantitative MR applications such as T1 mapping can potentially benefit from an accurate knowledge of variations of the transmitted RF field (B_1^+).

The purpose of this work is to investigate spatial homogeneity of the B_1^+ in the myocardium at 3.0T. For this study, we developed a prospective ECG-gated method based on DREAM (Dual Refocusing Echo Acquisition Mode).

The presented approach allows free breathing multi-shot acquisition B_1^+ mapping and its feasibility is shown in vivo.

Quality Assurance Phantoms and Procedures for UHF MRI – The German Ultrahigh Field Imaging (GUFI) Approach

Maximilian N. Voelker¹, Oliver Kraff¹, Eberhard Pracht², Astrid Wollrab³, Andreas K. Bitz⁴, Tony Stöcker², Harald H. Quick^{1,5}, Oliver Speck^{3,6}, and Mark E. Ladd^{1,4}

¹Erwin L. Hahn Institute for Magnetic Resonance Imaging, University of Duisburg-Essen, Essen, Germany, ²German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany, ³Otto-von-Guericke-University, Magdeburg, Germany, ⁴Medical Physics in Radiology, German Cancer Research Center (dkfz), Heidelberg, Germany, ⁵High Field and Hybrid MR Imaging, University Hospital Essen, University of Duisburg-Essen, ⁶Leibniz Institute for Neurobiology, Magdeburg, Germany

The German Ultrahigh Field Imaging network (GUFI, www.mr-gufi.de) is a user group of 13 German and neighboring sites that all operate a UHF (7T or 9.4T) MRI system. Due to the lack of common quality assurance (QA) procedures for UHF, GUFI started an initiative to unify QA procedures at these sites. A QA phantom and measurement protocol were developed especially for UHF that is currently being rolled out to all member sites. The QA data allow monitoring of individual system performance based on long-term data analysis or by comparison to pooled data from all sites.

Computer 108

Application of Magnetic Resonance Fingerprinting to evaluate degradation of Magnetic Resonance Imaging system

Imam Ahmed Shaik¹, Rajeshree Malage¹, and Sairam Geethanath¹¹Medical Imaging Research Centre (MIRC), Dayanada Sagar Institutions, Bangalore, India

Detection of artefact and its automated correction is an active area of MRI research. The aim of this study is to evaluate MR system/sub-system degradation and detection of root cause for image quality degradation using Magnetic Resonance Fingerprinting (MRF). The method is demonstrated on Terranova, an earth's field MR imager as part of the preliminary studies. The 3 major coils: polarizer, gradient and Audio Frequency (AF) coils were considered for degradation evaluation. A dictionary similar to MRF with 64 entries for different ranges of inputs was generated. It is shown that based on dictionary a decision can be made about the status of the system.

Computer 109

Characterization of a matrix gradient system using a magnetic field probe

Ying-Hua Chu^{1,2}, Sebastian Littin², Yi-Cheng Hsu^{1,2}, and Maxim Zaitsev²¹Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ²Medical Physics, Department of Radiology, University Medical Center Freiburg, Freiburg, Germany

Measuring GIRF using field probe and chirp gradient waveform is an efficient method to characterize the gradient behavior. We demonstrate that by measuring GIRF for each channel we are able to predict the response of simultaneously driven 12-channel gradient operation. Full characterization of the gradient system can be used to detect suboptimal matching of the amplifier and can be used to achieve desired performance also in such complex systems as matrix gradient coils.

3915

Computer 110

Accurate dynamic magnetic field monitoring and diffusion-weighted image reconstruction using uncorrelated local field measurements

Ying-Hua Chu¹, Yi-Cheng Hsu¹, and Fa-Hsuan Lin^{1,2}¹Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ²Department of Neuroscience and Biomedical Engineering, Aalto University, Espoo, Finland

We proposed a method to decouple field probes and to improve the accuracy of dynamic magnetic field estimation. A sensitivity matrix of probes was measured and to decouple NMR signals. Diffusion weighted phantom images with off-resonance characterized by decoupled probes had a more invariant structure than by coupled probes when diffusion sensitivity gradients along different directions were applied. The phantom image reconstructed with field disturbances estimated from decoupled probes also shows a more homogeneous background than from coupled probes. Human brain images also demonstrated the improved image quality when decoupled probes were used.

Computer 111

DREAM-based B₁-shimming for cardiac imaging at 7 TBart R. Steensma¹, Ingmar Voogt¹, Luijten R. Peter¹, Tim Leiner¹, Dennis W.J. Klomp¹, van den Berg A.T. Nico², and Alexander J.E. Raaijmakers^{1,3}¹Division Imaging, Department of Radiology, University Medical Center Utrecht, Utrecht, Netherlands, ²Division Imaging, Department of Radiotherapy, University Medical Center Utrecht, Utrecht, Netherlands, ³Biomedical Image Analysis, Eindhoven University of Technology, Eindhoven, Netherlands

RF shimming for multi-transmit systems is commonly performed by phase-only shimming. Improved B₁⁺ homogeneity is reached by phase-amplitude shimming but this requires knowledge of the B₁⁺ magnitude distributions. For cardiac imaging at 7 Tesla, the acquisition of these distributions is challenging. We present a DREAM-based acquisition series to reconstruct B₁⁺ magnitude maps in the heart. This method is applied to homogenize the transmit field for three subjects using phase-amplitude shimming. Results demonstrate a clear improvement of transmit field homogeneity in the heart in comparison to phase-only shimming without B₁⁺ magnitude information.

Computer 112

Interaction between trajectory deviations and B₀ field inhomogeneity in readout-segmented EPI and spiral imagingYoko A Spirig^{1,2}, Nadine N Graedel², Lars Kasper¹, Karla L Miller², Robert Frost², Stuart Clare², Klaas P Pruessmann¹, and S Johanna Vannesjo²¹Institute for Biomedical Engineering, University of Zurich and ETH Zurich, Zurich, Switzerland, ²FMRIB centre, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom

We studied the effect of encoding imperfections due to gradient errors with a focus on their interaction with B₀ inhomogeneities. Using a simulation framework, we retrospectively sampled data using k-space trajectories of two fast imaging sequences and compared reconstructions based on nominal, gradient impulse response (GIRF) predicted and measured (ground-truth) trajectories for spiral and readout-segmented EPI sequences. We found that the detrimental impact of trajectory imperfections on image quality is strongly amplified by B₀ inhomogeneities, especially for non-Cartesian trajectories. Furthermore, we confirmed that GIRF-predicted trajectory based reconstructions (requiring only a one-time calibration) allow effective artifact reduction.

3918

Computer 113

Robust Accelerated Reconstruction for Bloch-Siegert B₁-mappingAndreas Lesch¹, Matthias Schlögl¹, and Rudolf Stollberger^{1,2}¹Institute of Medical Engineering, Graz University of Technology, Graz, Austria, ²BioTechMed Graz, Graz, Austria

In this work we evaluate the performance and the robustness of an algorithm for the reconstruction of B1+-maps out of highly accelerated Bloch-Siegert data. The algorithm is based on variational modeling with a problem specific regularization approach. We evaluate the influence of different sampling patterns on the achievable accuracy and sampling efficiency and the influence of both regularization parameters on the final result. All results are compared to the fully-sampled reference using conventional reconstruction. We can show the general robustness of our algorithm and the most effective sampling pattern for this purpose.

[Field Mapping using bSSFP Elliptical Signal Model](#)

Meredith Taylor¹, Joseph Valentine¹, Steven Whitaker¹, Michael N Hoff², and Neal Bangerter¹

¹Electrical Engineering, Brigham Young University, Provo, UT, United States, ²University of Washington

It is well known that the bSSFP signal is highly dependent on the precession frequency off-resonance value at each pixel. The bSSFP signal can be modeled as an ellipse in the complex plane that rotates about the origin, with the degree of rotation depending on the regional off-resonance value. If a specific point on the axis of the ellipse could be localized, the phase of that point could be used to produce a field map. Xiang and Hoff came up with a geometric solution (GS) which removes banding artifacts by estimating a consistent cross point within the ellipse.

3921

Computer 116

[Magnetic Field Monitoring of Spiral Echo Train Imaging](#)

Craig H Meyer¹, Gudrun Ruyters², John P. Mugler III³, Samuel W. Fielden⁴, Berthold Kiefer⁵, and Josef Pfeuffer⁵

¹Biomedical Engineering, University of Virginia, Charlottesville, VA, United States, ²Physics, Siemens Healthineers GmbH, Erlangen, Germany, ³Radiology & Medical Imaging, University of Virginia, Charlottesville, VA, United States, ⁴Geisinger Health System, Lewisburg, PA, United States, ⁵Application Development, Siemens Healthineers GmbH, Erlangen, Germany

The goal of this study was to characterize the k-space trajectories of a spiral echo train pulse sequence using a dynamic field camera. The spiral trajectories were quite repeatable, with typical measured error less than 0.01% of the maximum k-space magnitude. This was true for constant-density, dual-density, and spiral-in/out trajectories. A somewhat larger error was typically observed in the first echo. Overall, this study demonstrates that 3D spiral echo train imaging using the same k-space estimation method for all echoes was sufficient to achieve high image quality.

Computer 117

[Assessing changes in MRI measurands incurred in a scanner upgrade: Is my study comprised?](#)

Kathryn E Keenan¹, Slavka Carnicka¹, Sophia C Gottlieb², and Karl F Stupic¹

¹Physical Measurement Laboratory, National Institute of Standards and Technology, Boulder, CO, United States, ²Bates College, Lewiston, ME, United States

Scanner upgrades due to software and hardware changes are an inevitable part of MR research and, without quality assurance protocols, can jeopardize studies. We used two standardized phantoms to evaluate change in T_1 relaxation time and ADC measurements on a system that underwent an 'everything but the magnet' upgrade. Post-upgrade, the ADC measurements are comparable or better than the pre-upgrade measurements, while T_1 measurements (VFA and IR) are affected by the upgrade. Upgrades can have unintended consequences, and we recommend the development of standardized quality assurance protocols that test not only contrast, but also quantitative measurements to identify variations and enable corrections.

3923

Computer 118

[A within-subject comparison of anatomical and diffusion scans from Siemens TimTrio and Prisma scanners](#)

Ross William Mair^{1,2} and Stephanie McMains¹

¹Center for Brain Science, Harvard University, Cambridge, MA, United States, ²Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Charlestown, MA, United States

Siemens' latest 3 Tesla scanner, the Magnetom Prisma, represents a significant upgrade in performance capability over the Magnetom TimTrio. To quantify the improvements offered by such a significant system upgrade, we scanned 8 subjects using a variety of anatomical, functional and diffusion protocols on the TimTrio platform, and then repeated the same protocols on the Prisma platform with the same subjects after the upgrade process. We found consistency in morphometric results from anatomical scans acquired using recommended T_1 -weighted imaging protocols. Modest improvements in tSNR for high-resolution and highly-slice accelerated BOLD scans were seen, but more traditional 3mm resolution scans yielded no improvement presumably due to the dominance of physiological noise. The DTI scans conducted here benefit greatly from the new gradient coil in the Prisma, when protocols are optimized to reduce TE and bandwidth as allowed by the new gradient set.

Computer 119

[Compensating for Eddy Current Effects in Motion-compensated Diffusion-prepared TSE Sequences](#)

Anh Tu Van¹, Barbara Cervantes², Hendrik Kooijman³, and Dimitrios C Karampinos²

¹IMETUM, Technical University of Munich, Garching, Germany, ²Department of Diagnostic and Interventional Radiology, Technical University of Munich, Munich, Germany, ³Philips Healthcare, Hamburg, Germany

Diffusion-prepared (dprep-TSE) TSE sequences are gaining attention for high-resolution distortion-free body DWI. However, dprep-TSE suffers from phase errors induced by both motion and eddy current effects. Motion compensation reduces motion effects, but eddy currents remain a source of phase errors. The present study investigates the performance of two alternative methods for compensating for eddy current effects in a motion-compensated dprep-TSE sequence: the use of phase cycling and the use of magnitude stabilizers.

A Three-Dimensional Spiral-In/Out Turbo-Spin-Echo Technique with Long Readout Echo Train and Concomitant Phase Compensation
Zhiqiang Li¹, John P Karis², and James G Pipe¹

¹Imaging Research, Barrow Neurological Institute, Phoenix, AZ, United States, ²Neuroradiology, Barrow Neurological Institute, Phoenix, AZ, United States

TSE is a rapid technique routinely used for T2 and FLAIR imaging. Three-Dimensional TSE with variable flip angles provides high scan efficiency, high SNR, and contiguous slice coverage. In this project we develop a 3D spiral TSE sequence employing a spiral-in/out readout for efficient acquisition but without the drawbacks associated with conventional spiral-out TSE. The variable flip angle schedule is adapted for long echo space to reduce waste in acquisition time. A concomitant phase compensation technique is incorporated to minimize the violation of the CPMG condition. Preliminary results demonstrate the feasibility of the proposed technique.

More than meets the eye: Quantitative evaluation of prospective motion correction at 7T
Hendrik Mattern¹, Falk Lüsebrink¹, Alessandro Sciarra¹, and Oliver Speck^{1,2,3,4}

¹BMMR, Otto-von-Guericke-University, Magdeburg, Germany, ²German Center for Neurodegenerative Disease, Magdeburg, Germany, ³Center for Behavioral Brain Sciences, Magdeburg, Germany, ⁴Leibniz Institute for Neurobiology, Magdeburg, Germany

Prospective motion correction inherently does not provide uncorrected images. Thus, for image assessment usually motion corrected and uncorrected data from two different scans – therefore with different motion patterns – are qualitatively compared. In this study, prospectively corrected data from a highly trained cohort is retrospectively decorrected to enable a quantitative assessment with image-based and segmentation-based metrics. The results indicate that for the observed small-scale, involuntary subject motion quantitative rather than qualitative assessment is necessary to estimate the image degradation.

Head movement is a major issue in dynamic brain PET imaging. The introduction of a simultaneous MR-PET scanner enabled new opportunities to use MR information for PET motion correction. Here we present a novel method based on routinely acquired MRI sequences. Multi-contrast MR images are co-registered to extract motion parameters. These motion parameters are then used to guide PET image reconstruction. Results on both phantom and human data provide evidences that this method can significantly enhance image contrast and reduce motion artefact in brain PET images, without affecting MR protocol.

A Registration Framework for Prostate mpMRI via Combining Intensity and Shape Information

Xia Li¹, Sandeep Gupta¹, Rakesh Mullick², Oguz Akin³, and Dattesh Shanbhag²

¹GE Global Research Center, Niskayuna, NY, United States, ²GE Global Research Center, Bengaluru, India, ³Memorial Sloan-Kettering Cancer Center, New York, NY, United States

In prostate MRI, tissue alignment between T2w and DWI can be challenging due to elastic distortions in DWI induced by fast switching of gradients. In this work, we propose a joint approach to perform registration between DWI and T2w on the prostate data, by considering both image intensity and prostate gland shape information. After rigid alignment between segmented prostate masks, surface points on the prostate masks were extracted and Gaussian mixture model was used to build shape correspondence. The shape information was integrated into mutual-information based deformable registration to constrain undesired distortions. The proposed framework was compared with other strategies and demonstrated the best registration accuracy (DICE = 0.91 between T2 and DWI based prostate masks).

Computer 80

Effect of head motion on B₀ shimming based on magnetic field probes

Joep Wezel¹, Andrew G. Webb¹, and Matthias J. van Osch¹

¹Radiology, Leiden University Medical Center, Leiden, Netherlands

Magnetic field probes (FP) can be used to monitor B₀-changes and this approach has shown great potential for real time correction of artifacts produced by such changes. When estimating B₀ fluctuations in the brain it is, however, not known how head motion influences the FP-based B₀-estimation. Head motion introduces a B₀-change both inside and outside the head, this study assesses the impact on field probe estimated B₀-distributions within the brain at 7 Tesla. FP based correction after head motion can actually lead to a higher error especially evident when using third order spherical harmonics. Improved performance is, however, identified when using first order spherical harmonics.

Computer 81

A generalized prospective motion correction framework for improved spectroscopy, structural and angiographic imaging

Mads Andersen¹, Vincent Olthman Boer², Anouk Marsman², and Esben Thade Petersen^{2,3}

¹Philips Healthcare, Copenhagen, Denmark, ²Danish Research Centre for Magnetic Resonance, Centre for Functional and Diagnostic Imaging and Research, Copenhagen University Hospital Hvidovre, Denmark, ³Electrical Engineering, Technical University of Denmark, Lyngby, Denmark

Subject motion is a major problem in brain imaging and spectroscopy, misleading diagnosis in the clinic and lowering data quality in research. A promising solution is to update the field-of-view in real time based on tracking with volumetric navigators. This was implemented using a new interleaved scanning framework and a product functionality for self-navigation of fMRI. The implementation is simple to use and very flexible, as the navigator and target sequence are simply defined as two different scans, that can be interleaved at any level. It was demonstrated to improve motion robustness in single voxel spectroscopy, T1-weighted imaging and angiography.

Computer 82

[One-Dimensional Phase Navigation of Diffusion-Weighted 3D TSE for High Resolution Musculoskeletal Diffusion Imaging](#)

Barbara Cervantes¹, Anh T Van², Hendrik Kooijman³, Kim van de Ven⁴, Andreas Hock³, Ernst J Rummeny¹, Jan S Kirschke⁵, and Dimitrios C Karampinos¹

¹Department of Diagnostic and Interventional Radiology, Technical University of Munich, Munich, Germany, ²IMETUM, Technical University of Munich, Garching, Germany, ³Philips Healthcare, Hamburg, Germany, ⁴Philips Healthcare, Best, Netherlands, ⁵Department of Neuroradiology, Technical University of Munich, Munich, Germany

Diffusion-prepared 3D TSE (dprep-3D-TSE) imaging has been recently applied for high-resolution distortion-free body and musculoskeletal DWI. Dprep-3D-TSE has been combined with magnitude stabilizers to reduce magnitude modulation effects induced by both motion and eddy current effects. In addition, velocity compensation has been proposed to reduce motion-induced phase modulation effects. However, given that dprep-3D-TSE is a multi-shot diffusion technique, it suffers from motion-induced phase variation effects across different shots and it requires phase navigation. The purpose of the present study is to develop an acquisition and phase correction scheme for one-dimensional phase navigation of dprep-3D-TSE imaging.

[Optical Motion Monitoring for Abdominal and Lung Imaging](#)

Joseph Y. Cheng¹, Jonathan Lu², Grieg Scott², and Shreyas S. Vasanawala¹

¹Department of Radiology, Stanford University, Stanford, CA, United States, ²Department of Electrical Engineering, Stanford University, Stanford, CA, United States

The accuracy to compensate or correct for MR image artifacts from motion depends on the ability to precisely measure patient motion. Optical cameras are a compelling solution as they simplify patient setup and do not negatively impact MR data acquisition. However, most efforts have been focused on integrating and applying optical cameras to neuroimaging. In this work, setup and methods for video processing were developed for lung and abdominal MRI where MRI acquisition is especially sensitive to motion. The proposed solution had high correlation with conventional approaches of respiratory bellows and MRI navigators; also, comparable image quality was achieved.

[Joint Non-Rigid Motion Estimation and Image Reconstruction via Sparse Blind Deconvolution](#)

Frank Ong¹ and Michael Lustig¹

¹Electrical Engineering and Computer Sciences, University of California, Berkeley, Berkeley, CA, United States

We propose a non-parametric method of jointly estimating non-rigid motion and the underlying image without the assumption of motion smoothness. We model non-rigid motion as local linear translation, which is equivalent to convolution with 1-sparse kernels. We then pose the non-rigid motion recovery problem as a sparse blind deconvolution problem. Our reconstruction results demonstrate that non-rigid motion can be well approximated as local translation motion using the proposed method. The proposed formulation can also be viewed as a generalization of locally low rank reconstruction.

[Exploring the Sensitivity of Magnetic Resonance Fingerprinting to Different Types of Motion and Possible Correction Mechanisms](#)

Zidan Yu^{1,2,3}, Tiejun Zhao^{1,2,4}, Jakob Assländer^{1,2}, Riccardo Lattanzi^{1,2,3}, Daniel K Sodickson^{1,2,3}, and Martijn A Cloos^{1,2,3}

¹Bernard and Irene Schwartz Center for Biomedical Imaging, Department of Radiology, New York University School of Medicine, New York, NY, United States, ²Center for Advanced Imaging Innovation and Research (CAI2R), Department of Radiology, New York University School of Medicine, New York, NY, United States, ³The Sackler Institute of Graduate Biomedical Sciences, New York University School of Medicine, New York, NY, United States, ⁴Siemens Medical Solutions USA, Inc., Siemens Healthineers, New York, NY, United States

In this work, we experimentally explore the sensitivity of Magnetic Resonance Fingerprinting (MRF) to various types of motion at different time intervals during the scan. Our results show that the T1 values are least affected by motion, but the maps may be blurred if the motion occurs early in the scan. Also, motion in the middle of the scan leads to a systematic underestimation in T2. In addition, we show that simply removing the corrupted time-points from the data can restore quantitative parameter values to the correct range.

[Reconstruction of highly accelerated free-breathing 3D abdominal MRI using Stacked Convolutional Auto-Encoder Network](#)

Jun Lv¹, Kun Chen¹, Ming Yang², Jue Zhang^{1,3}, Xiaoying Wang^{1,4}, and Jing Fang^{1,3}

¹Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, People's Republic of China, ²Philips Healthcare, Suzhou, People's Republic of China, ³College of Engineering, Peking University, Beijing, People's Republic of China, ⁴Department of Radiology, Peking University First Hospital, Beijing, People's Republic of China

Free-breathing 3D abdominal imaging is a challenging task for MRI since respiratory motion severely degrades image quality. Our purpose is to develop a novel reconstruction approach for highly accelerated free-breathing 3D abdominal images with stacked convolutional auto-encoders. The whole structure of our proposed method consists of 9 hidden layers except to input and output layer. The proposed method achieves similar quality to the whole sampling reconstruction with non-significant differences for structural similarity index measure (SSIM) (0.99 and 1.00, respectively). Moreover, the average reconstruction time is very short (about 0.25 s/image). Therefore, our method should be employed for a wide range of clinical applications.

[Real-time prospective bulk motion exclusion for robust 3D free-breathing abdominal imaging](#)

Bjorn Stemkens^{1,2,3}, Thomas Benkert^{2,3}, Hersh Chandarana^{2,3}, Cornelis A.T. Van den Berg¹, Jan J.W. Lagendijk¹, Daniel K. Sodickson^{2,3}, Rob H.N. Tijssen¹, and Kai Tobias Block^{2,3}

¹Department of Radiotherapy, University Medical Center Utrecht, Utrecht, Netherlands, ²Center of Advanced Imaging Innovation and Research (CAI2R), Department of Radiology, New York University School of Medicine, New York, NY, United States, ³Bernard and Irene Schwartz Center for Biomedical Imaging, Department of Radiology, New York University School of Medicine, New York, NY, United States

3D free-breathing approaches have shown potential for abdominal imaging in patients who are unable performing breath-holds, such as pediatric patients and uncooperative adults. However, these free-breathing techniques fail when bulk motion occurs. This study proposes a method to detect and exclude such bulk motion to ensure diagnostic image quality, even in this challenging group of patients. Without requiring user interaction, this technique improves robustness for abdominal MR imaging, while minimizing the scan time on an individual basis, using a real-time implementation on the MRI system, which may enable robust non-sedated pediatric imaging.

[Radial MRI and model-based iterative reconstruction for motion robust quantification of the water content in the brain at 3 Tesla](#)

Markus Zimmermann¹, Zaheer Abbas^{1,2}, Dominik Ridder¹, Ana-Maria Oros-Peusquens¹, and N. Jon Shah^{1,2}

¹Institute of Neuroscience and Medicine – 4, Medical Imaging Physics, Forschungszentrum Juelich GmbH, Juelich, Germany, ²Department of Neurology, Faculty of Medicine, RWTH Aachen University, JARA, Aachen, Germany

Quantitative water content mapping is a promising technique to monitor brain diseases. However, established protocols suffer from long acquisition times and sensitivity to patient motion. To overcome these issues, we propose to use golden angle radial MRI and model-based iterative reconstruction. This allows accurate and precise estimation of water content and T_1 values, while providing significantly higher motion robustness, as shown in phantom and in vivo experiments. The golden angle-based k-space sampling allows for a nearly optimal k-space coverage even in the event of early termination of measurement. This opens the opportunity to apply such a technique in the clinic.

Computer 90

[A head motion model for fusion of patient pose measurements from different sensing modalities.](#)

Adam M. J. van Niekerk¹, Ernesta M. Meintjes¹, and Andre J. W. van der Kouwe^{1,2,3}

¹Division of Biomedical Engineering, Human Biology, University of Cape Town, Cape Town, South Africa, ²Athinoula A. Martinos Center, Massachusetts General Hospital, Charlestown, MA, United States, ³Radiology, Harvard Medical School, Boston, MA, United States

In this work we aim to address the challenges of fusing motion parameters measured using different sensing modalities, as temporal resolutions differ widely between navigator and external motion tracking techniques. A model is presented in which head motion is characterised as simple rolling motion. The resulting equations describe subject motion to within 2 mm when applied in an open loop manner. A filter, with feedback, is then implemented where navigator data is used to estimate model parameters. The filtered translation output is smooth without the cost of increased latency due to the fast orientation estimates.

Computer 91

[Accurate High-speed 3D-Registration of EPI vNavs for Head Motion Correction](#)

Yingzhuo Zhang¹, Iman Aganj^{2,3}, André J.W. van der Kouwe^{2,3}, and Matthew Dylan Tisdall⁴

¹John A. Paulson School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, United States, ²Athinoula A. Martinos Center for Biomedical Imaging, Radiology Department, Massachusetts General Hospital, Charlestown, MA, United States, ³Department of Radiology, Harvard Medical School, Boston, MA, United States, ⁴Department of Radiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States

Low-resolution, whole-head volumes can be acquired rapidly with EPI-based volumetric navigators (vNavs). vNavs interspersed in a longer scan are widely used for prospective motion correction in a variety of sequences. To further improve the accuracy and flexibility of vNavs, we present a novel registration algorithm, tailored specifically for the vNavs application. Accuracy of the algorithm is tested on navigator volumes acquired with human volunteers at three isotropic resolutions, 6.4mm, 8mm, and 10mm, using a series of field of view (FOV) rotations and translations to provide ground truth rigid "motion".

Regularly Incremented Phase Encoding Magnetic Resonance Fingerprinting (RIPE-MRF) for Enhanced Motion Suppression in Cartesian MRF
Christian Anderson¹, Charlie Wang¹, Yuning Gu¹, Mark Griswold^{1,2}, Xin Yu^{1,2,3}, and Chris Flack^{1,2,4}

¹Biomedical Engineering, Case Western Reserve University, Cleveland, OH, United States, ²Radiology, University Hospitals Cleveland Medical Center, Cleveland, OH, United States, ³Physiology and Biophysics, Case Western Reserve University, Cleveland, OH, United States, ⁴Pediatrics, University Hospitals Cleveland Medical Center, Cleveland, OH, United States

Preclinical quantitative MRI is susceptible to the motion artifacts caused by the rapid respiratory motion and high heart rates present in small animals. This can be alleviated through the use of gating/triggering but these are difficult to implement in magnetic resonance fingerprinting due to the need for dynamic, coherent signal evolutions. We propose a method for an incremented phase encoding MRF acquisition that enhances motion suppression in Cartesian MRF. This phase incremented strategy distributes motion artifacts throughout the acquisition creating incoherent artifacts allowing the MRF method to "see through" the artifacts and produce artifact free T1 and T2 maps.

Computer 93

A novel and robust reconstruction method for free-breathing cine DENSE by minimizing k-space entropy

Xiaoying Cai¹, Kenneth C Bilchick², and Frederick H Epstein^{1,3}

¹Biomedical Engineering, University of Virginia, Charlottesville, VA, United States, ²Medicine, University of Virginia, Charlottesville, VA, United States, ³Radiology, University of Virginia

A reliable free-breathing (FB) cine DENSE method would benefit myocardial strain imaging in many patients. An echo due to T1 relaxation is an important source of artifacts, particularly for free-breathing acquisitions. We propose to optimize suppression of these echoes by minimizing k-space entropy. The method was tested in 10 subjects (6 healthy volunteers and 4 heart failure patients) and compared to a conventional diaphragm navigator method (dNAV). Image reconstruction by minimizing k-space entropy provided better image quality than the conventional dNAV method.

Motion-Robustness Evaluation and Motion Correction of Wave-Encoding

Feyu Chen¹, Joseph Y Cheng², Tao Zhang³, John M Pauly¹, and Shreyas S Vasanawala²

¹Electrical Engineering, Stanford University, Stanford, CA, United States, ²Radiology, Stanford University, Stanford, CA, United States, ³Global MR Applications and Workflow, GE Healthcare, Houston, TX, United States

The motion-robustness of a 3D wave-encoded SPGR sequence was evaluated by simulating the acquisition of a Gaussian-profile object with periodic motion. Compared with non-wave-encoded sampling, wave-encoding provides better motion property because of wider diffusion of motion artifacts. A motion-correction method was also proposed for wave-encoding based on 3D translational motion estimates. This motion-correction method is demonstrated to effectively reduce motion artifacts in wave-encoded scans.

3948

Computer 95

Simultaneous motion and B0 correction using FID-SNAVs

Patricia M Johnson^{1,2}, Junmin Liu¹, and Maria Drangova^{1,2}

¹Robarts Research Institute, London, ON, Canada, ²Department of Medical Biophysics, Schulich School of Medicine and Dentistry, Western University, London, ON, Canada

Global B₀ shifts caused by subject motion and scanner heating, result in phase inconsistencies, which lead to image artefacts. In this work, an FID readout is added to Spherical Navigator Echoes (FID-SNAVs) in order to perform retrospective motion and frequency shift (Δf) correction. The accuracy of FID-SNAVs in measuring Δf is evaluated, and simultaneous Δf and motion measurement is demonstrated in phantom experiments. FID-SNAVs estimate Δf accurately, and shifts of approximately -10 to 6Hz are measured during translations of ± 1.5 cm. Combined Δf and motion correction demonstrates dramatic improvement of image quality compared to motion correction alone.

Computer 96

3D motion quantification based on the temporal evolution of the noise covariance matrix of a receive array

Robin J.M. Navest¹, Anna Andreychenko¹, Jan J.W. Lagendijk¹, Baudouin Denis de Senneville^{1,2}, and Cornelis A.T. van den Berg¹

¹Department of Radiotherapy, Center for Image Sciences, University Medical Center Utrecht, Utrecht, Netherlands, ²IMB, UMR 5251 CNRS/University of Bordeaux, Bordeaux, France

Motion quantification is essential for successful MR imaging and MRI guided radiotherapy of mobile organs. Currently, 3D MRI is too slow to quantify organ displacements and a motion model could alternatively be used for tracking and/or motion compensation. A motion model trained on MRI data and driven by the noise covariance matrix (NCM) of a receive array is proposed to quantify internal anatomy motion. Passive thermal noise measurements have a high temporal resolution (~10ms) and do not interfere with or rely on MR signal. Abdominal organ displacement can be accurately estimated in 3D, through the NCM of the receive array.

[A Fast Interleaved Bipolar Imaging Method for Fat Quantification](#)

JaeJin Cho¹, Hyunseok Seo¹, Kinam Kwon¹, Seohee So¹, Byungjai Kim¹, and HyunWook Park¹

¹Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of

The fat quantification using the bipolar multi-echo signals has several benefits such as fast imaging time, SNR, resolution, and robust separation. However, the fat quantification using the bipolar multi-echo signals suffers from the bipolar artifacts due to the imperfect gradient. In this abstract, to overcome these problems, fat quantification is independently performed for each polarity of the readout gradient. Because the acquisition of fully sampled data takes too much time, a new interpolation method for interleaved bipolar multi-gradient-echo acquisition is proposed, which uses the low-rankness of entire data. The experiment results show that the proposed method successfully quantifies the correct fat fraction without bipolar artifacts in a short imaging time.

[Gradient Field Design for RF Excitation in Simultaneous Multi-Slice and Simultaneous Multi-Slab Imaging by Using a Z-Gradient Array](#)

Koray Ertan¹, Soheil Taraghinia¹, Hamed Mohammadi², and Ergin Atalar¹

¹National Magnetic Resonance Research Center (UMRAM), Bilkent University, Ankara, Turkey, ²Electrical and Electronics Engineering, Bilkent University, Ankara, Turkey

Multiple locations inside the volume of interest can be mapped to same frequency by applying spatially oscillating magnetic fields (SOMFs) created by 9 channel z-gradient array. Such a mapping can lead to excitation of multiple slices or slabs with a single band RF pulse as well as doubling the number of slices excited by a multi-band RF pulse. Depending on the slice or slab locations, spatially oscillating magnetic fields can be shifted using a independent gradient amplifiers. We have demonstrated 2 slab excitation with a single band RF pulse and 6 slice excitation with a 3-band RF pulse.

[Simultaneous Variable-slab Dual-echo TOF MR Angiography and Susceptibility-Weighted Imaging](#)

Won-Joon Do¹, Seung Hong Choi², and Sung-Hong Park³

¹Dept. of Bio and Brain Engineering, KAIST, Daejeon, Korea, Republic of, ²Dept. of Radiology, Seoul National University Hospital, Seoul, Korea, Republic of, ³Dept. of Bio and Brain Engineering, KAIST, Daejeon, Korea, Republic of

Multi-slab time of flight MR angiogram (TOF MRA) provides more detailed vascular structure than single-slab MRA, whereas single-slab susceptibility weighed imaging (SWI) provides better SNR than multi-slab SWI. In previous CODEA study, conflicting requirement on number of slab was not solved. In this study, we proposed and demonstrated an efficient method to acquire TOF MRA and SWI simultaneously with different number of slabs using variable-slab CODEA, which suppressed slab boundary artifacts in TOF MRA. Also demonstrated was acceleration of the variable-slab CODEA with a parallel imaging technique, GRAPPA. These improvements would provide more diverse clinical information in a limited scan time.

Spatial biases in Magnetic Resonance Fingerprinting parameter maps arising from undersampling patterns

Gregor Kördörfer^{1,2}, Thomas Kluge¹, Josef Pfeuffer¹, Matthias Gebhardt³, Dan Ma⁴, Yun Jiang⁴, Mark Griswold^{4,5}, and Mathias Nittka¹

¹Application Development, Siemens Healthcare, Erlangen, Germany, ²Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany, ³Physics department, Siemens Healthcare, ⁴Department of Biomedical Engineering, Case Western Reserve University, OH, United States, ⁵Dept. of Radiology, Case Western Reserve University and University Hospitals of Cleveland, OH, United States

Magnetic Resonance Fingerprinting (MRF) is an MR technique that generates parameter maps by matching pseudo randomly generated MR signals with a precalculated dictionary. In order to acquire the signals in a reasonable time, rapid imaging techniques with high undersampling factors are necessary. We show a detailed analysis of the artifacts originating from this and their impact on measured signals and subsequently on parameter maps. Additionally, an analytical approach of predicting undersampling artifacts is proposed. With the help of this approach, a more robust and time efficient sampling of signals in MRF can be designed.

Fast T1 Correction for Fat Quantification using a Dual-TR Chemical Shift Encoded MRI Acquisition

Xiaoke Wang^{1,2}, Diego Hernando^{2,3}, Curtis N Wiens², and Scott Reeder^{1,2,3,4,5}

¹Biomedical Engineering, University of Wisconsin-Madison, Madison, WI, United States, ²Radiology, University of Wisconsin-Madison, Madison, WI, United States, ³Medical Physics, University of Wisconsin-Madison, Madison, WI, United States, ⁴Emergency Medicine, University of Wisconsin-Madison, Madison, WI, United States, ⁵Medicine, University of Wisconsin-Madison, Madison, WI, United States

Dual flip angle (DFA) methods facilitate T1-corrected proton density fat-fraction (PDFF) quantification at the cost of doubling scan time compared to small flip angle (SFA) methods. In this study, a novel "dual-TR" (DTR) fat quantification strategy was proposed. It acquired 2 spoiled gradient echo (SGRE) dataset sequentially, one with a shortened echo train and reduced TR to alleviate scan time penalties. Monte-Carlo simulation and Cramer-Rao lower bound demonstrated improved noise performance using the proposed method compared with SFA and DFA methods. Phantom experiments demonstrated the feasibility of T1-corrected PDFF estimates using the proposed DTR method.

Partial Fourier techniques in single-shot cross-term spatiotemporal encoding (xSPEN) MRI

Zhiyong Zhang¹ and Lucio Frydman¹

¹Weizmann Institute of Science, Rehovot, Israel

xSPEN is a new single-shot imaging approach with exceptional resilience to field heterogeneities: its images do not suffer from miss-registrations, require a priori information nor use post-acquisition corrections, to deliver faithfully the spins' spatial distribution. xSPEN, however, suffers from SNR penalties due to its non-Fourier nature and its considerable diffusion losses—especially when desiring high resolution. This study introduces partial Fourier transform approaches that acting along either the readout or the spatiotemporally-encoded dimensions, reduce both of these penalties. The principles of these partial FT methods are given, and applications in materials, preclinical and human single-shot xSPEN imaging are presented.

Computer 16

Optimized Trajectory Dual-Echo Fat and Water Separation

Hyungseok Jang¹ and Alan B McMillan¹

¹Department of Radiology, University of Wisconsin, Madison, WI, United States

Two-point Dixon methods enable robust fat suppression particularly in body and abdominal applications where large field of view imaging is required. However, a limitation of this approach is the decreased efficiency and longer TR's necessary to acquire multiple echoes. Furthermore, due to system performance constraints, flexible choice of image parameters necessary to obtain near in and out-of-phase echo times limits valid combinations of field of view, matrix size, and encoding bandwidth. In this study, we describe a novel, generalized framework to optimize a ramp-sampled readout, which allows reduced scan time, flexible parameter selection, and improved quantitative fat and water separation.

3966

Reference-Free Distortion Correction with Segmented Partial Fourier Acquisitions for High Resolution DTI at 7T

Michael Herbst¹, Benedikt A Poser², and Marco Reisert¹

¹Dept. of Radiology, Medical Physics, University Medical Center Freiburg, Freiburg, Germany, ²Department of Cognitive Neuroscience, Maastricht Brain Imaging Centre (MBIC)

Single-Shot diffusion weighted echo planar imaging (EPI) is known for its strong distortions due to long imaging readouts. However, even for segmented acquisitions, high resolution diffusion weighted imaging suffers from image distortions. Our approach shows that intrinsic field information of a segmented DTI acquisition can be used for robust distortion correction without blurring effects. In addition this approach offers the advantage to reduce artifacts from partial Fourier (PF) acquisitions due to better data distribution in k-space. In combination with the MUSE approach, this promising technique is applied to whole brain DTI with a resolution of 1mm isotropic.

Evaluation of phase-cycled bSSFP for qMT mapping in the brain in off-resonance conditions

Nicholas G Dowell¹, Nathan Evans², and Mara Cercignani¹

¹CISC, BSMS, Brighton, United Kingdom, ²Physics, University of Sussex, Brighton, United Kingdom

The balanced steady-state free precession acquisition approach is well-suited to quantitative magnetization transfer studies, owing to intrinsic MT weighting, rapid acquisition times and good SNR. However, the presence of off-resonance banding artefacts have limited its use, especially at B0 > 1.5T. This work is the first to evaluate a phase-cycled approach to bSSFP that can remove banding artefacts by taking maximum intensity projection MIP or taking a weighted mean as part of the qMT analysis. We conclude that neither MIP and weighted mean alone are capable of fully removing banding artefacts from qMT maps.

Computer 21

Field-of-View Packing and k-Space Fast Sampling

Yudong Zhu¹

¹Zhu Consulting, Scarsdale, NY, United States

By natural or artificial arrangement, excited spins may cluster in discrete areas of a multi-dimensional image-space. By leveraging gaps in-between, one may under-sample k-space while preserving the ability to map the spin distribution. FOV-packing is a new technology that maximizes efficiency mapping gapped distribution (spatially, spectrally and etc.) and extends reach. When applied to simultaneous multi-slice MRI, it leads to a unique technique that is speedy (due to sampling of image space and acceleration of encoding), with \sqrt{N} SNR scaling (due to volumetric encoding's noise averaging effect) and super-resolution capability (due to FOV packing and the option of resolving sub-slices).

Density Optimized Low-Discrepancy k-Space Trajectory for Accelerated Single-Point Imaging

Tobias Speidel¹ and Volker Rasche²

¹Core Facility Small Animal Imaging, University of Ulm, Ulm, Germany, ²Department of Internal Medicine II, University of Ulm, Ulm, Germany

Single-point imaging (SPI) methods are a rarely discussed topic due to the related long acquisition times. However, single-point imaging sequences provide a powerful tool for the suppression of susceptibility and chemical shift artefacts. Additionally, single-point imaging methods exhibit the intrinsic possibility of arbitrary sampling, which makes them predestinated for the combination with imaging acceleration methods, such as Compressed Sensing as a type of non-linear optimization. In this work, we present a three-dimensional spherical SPI quasi-random MRI trajectory, generated using low-discrepancy algorithms with density-optimized centre-oversampling, capable of high undersampling and metal-artefact suppression.

B0 Mapping of Highly Inhomogeneous Fields using Missing-Pulse Steady-State Free Precession (MP-SSFP)

Naoharu Kobayashi¹, Djaudat Idiyatullin¹, Gregor Adriany¹, and Michael Garwood¹

¹Center for Magnetic Resonance Research, Department of Radiology, University of Minnesota, Minneapolis, MN, United States

A B_0 mapping of highly inhomogeneous fields is introduced. The method acquires refocused echo signals generated by a missing-pulse steady-state free precession (MP-SSFP) sequence with three-dimensional phase-encoding gradients. A B_0 map is calculated from the refocusing and dephasing of spin phase around the echo centers. Validation was performed in a phantom experiment conducted with a permanently inhomogeneous field produced by mounting a head gradient coil at 36 cm out of the isocenter of a 90-cm 4T magnet. Using the measured B_0 field map, we demonstrate correction of image distortion caused by the extremely nonlinear inhomogeneous B_0 field.

In-vivo Segmentation of Carotid Plaque MRI with Deep Convolutional Neural Networks

Yuxi Dong¹, Yuchao Pan¹, Rui Li², and Wei Xu¹

¹Institute for Interdisciplinary Information Sciences, Tsinghua University, Beijing, People's Republic of China, ²Center for Biomedical Imaging Research, Tsinghua University, Beijing, People's Republic of China

MRI is gaining popularity for identifying atherosclerosis, a common disease caused by the accumulation of cholesterol in arteries. To identify vulnerable plaque, the components in plaque need to be segmented by radiologist manually, which is both hard and tedious. Previous attempts to solve the problem using probability maps are limited by their accuracy. We leverage the recently developed convolutional neural networks (CNN) to build a model based on 1,000 subjects automatically, achieving significantly better accuracy in almost every metric over traditional methods.

Deep network training based sparsity model for reconstruction

Jiahao Lin^{1,2}, Stamatios Lefkimmiatis³, and Kyunghyun Sung²

¹Electrical Engineering, University of California, Los Angeles, Los Angeles, CA, United States, ²Radiology, University of California, Los Angeles, Los Angeles, CA, United States, ³Skolkovo Institute of Science and Technology, Moscow, Russian Federation

One challenge for MR reconstruction is to heuristically select the appropriate regularizer for the optimization problem. This abstract proposes a novel deep learning based reconstruction approach for accelerated MR imaging. With the training using clinical MR images and their retrospectively undersampled noisy images, this algorithm learns the specific parameters of a general regularizer for the optimization problem, and uses this regularizer in the iterative reconstruction to achieves high image quality with high acceleration factors.

Super resolution reconstruction in MRI by deep convolutional neural networks

zhengchao dong¹ and hong Wang²

¹1. Columbia University, New York, NY, United States 2. New York State Psychiatric institute, New York, NY, United States, NY, United States, ²1. Columbia University, New York, NY, United States 2. School of Science, Tianjin University, Tianjin, People's Republic of China

The sparse-representation-based super resolution is an efficient learning-based method. This method involves two key steps. One is to learn two dictionaries for low/high-resolution image patches, and the other is to learn a mapping between low resolution example patches and their corresponding high resolution patches from massive external images. We presented a super resolution method for MRI from reduced k-space acquisition sequences via deep convolutional neural networks. The proposed method directly learns an end-to-end mapping between the low/high-resolution images. Our proposed method is tested on the OpenfMRI database. It significantly outperforms the zero-filled reconstruction and an existing learning-based MRI SR method.

Automated reference-free assessment of MR image quality using an active learning approach: Comparison of Support Vector Machine versus Deep Neural Network classification.

Sergios Gatidis¹, Annika Liebgott¹, Martin Schwartz¹, Petros Martirosian¹, Fritz Schick¹, Konstantin Nikolaou¹, Bin Yang², and Thomas Küstner^{1,2}

¹*Department of Radiology, University of Tuebingen, Tuebingen, Germany,* ²*Institute of Signal Processing and System Theory, University of Stuttgart*

In this study we compare the performance of Support Vector Machine (SVM)-based and Deep Neural Network (DNN)-based active learning for automated assessment of MR image quality. MR images were labeled by radiologists concerning perceived image quality and used as training and test data. DNN and SVM were trained to classify image quality on the training data. An active learning scheme was used for optimization of the training procedure. We found that using active learning with either SVM- or DNN- based classification allows for accurate and efficient automated assessment of MR image quality.

Fat/Water Classification Using a Supervised Neural Network

Anne Menini¹, Kang Wang², Zachary W. Slavens³, and Christopher J. Hardy⁴

¹*GE Global Research, Munich, Germany,* ²*Global MR Applications & Workflow, GE Healthcare, Madison, WI, United States,* ³*GE Healthcare, Waukesha, WI, United States,* ⁴*GE Global Research, Niskayuna, NY, United States*

Fat/Water classification methods relying on image intensity histograms or hydrogen chemical-shift spectra can be subject to failure when assumptions in the algorithm are not met. In this study, we propose a new classification method based entirely on machine learning. Different neural network types were trained and tested on databases covering various anatomies, RF-coil types and image contrasts. A 2D paired classification using a fully connected neural network was capable of reliably classifying fat versus water with an accuracy of 100% on test data sets different from the training data, with a clinically relevant processing time of 0.05 s per case.

Artificial Neural Network for Suppression of Banding Artifacts in Balanced Steady-State Free Precession MRI

Ki Hwan Kim^{1,2} and Sung-Hong Park^{1,2}

¹*Department of Bio and Brain Engineering, Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of,*

²*Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of*

This study is the first attempt for a learning-based algorithm to be applied to banding artifact suppression in balanced steady-state free precession (bSSFP). We trained multilayer perceptron (MLP) models with two or four phase-cycling datasets and banding-free datasets as inputs and outputs, respectively. We demonstrated that MLP was superior to existing methods in terms of banding artifact suppression and SNR efficiency, which was clearer in two phase-cycling datasets. Furthermore, MLP was widely applicable to various image sets, irrespective of scan parameters, body organs, and field strengths. The learning-based approach is promising for banding artifact suppression of bSSFP.

Boosting SNR and/or Resolution of Arterial Spin Label (ASL) imaging using Multi-contrast Approaches with Multi-lateral Guided Filter and Deep Networks

Enhao Gong¹, John Pauly¹, and Greg Zaharchuk²

¹*Electrical Engineering, Stanford University, Stanford, CA, United States,* ²*Radiology, Stanford University, Stanford, CA, United States*

Arterial Spin Labeling (ASL) MRI is a powerful neuro imaging tool which provides quantitative perfusion maps. However, ASL perfusion maps typically suffer from low SNR and resolution. Averaging from multiple scans (high Nex value) can improve the SNR but at the cost of significantly increased acquisition time. In the work we proposed a technique for improved ASL image quality with boosted SNR and/or resolution by 1) incorporating the information of multi-contrast images 2) using nonlinear, non-local, spatial variant multi-lateral filtering, 3) training a deep network model to adaptively tune the final denoising level and further boost the SNR and improve image quality. Various in-vivo experiments demonstrate the superior performance of the proposed method which will significantly accelerate ASL acquisition and improve image quality.

[Undersampling trajectory design for fast MRI with super-resolution convolutional neural network](#)
Shanshan Wang¹, Taohui Xiao^{1,2}, Sha Tan^{1,3}, Yuanyuan Liu¹, Leslie Ying⁴, and Dong Liang¹

¹Paul C. Lauterbur Research Center for Biomedical Imaging, SIAT, Chinese Academy of Sciences, Shenzhen, People's Republic of China, ²School of Physics and Optoelectronics, Xiangtan University, Xiangtan, People's Republic of China, ³School of Information Engineering, Guangdong University of Technology, Guangzhou, People's Republic of China, ⁴Department of Biomedical Engineering and Department of Electrical Engineering, The State University of New York, NY, United States

Deep learning based fast MR imaging (DeepLearnMRI) has been an appealing new research direction, which utilizes networks to draw valuable prior information from enormous existing high-quality MR images and then assists accurate MR image reconstruction from undersampled data. This paper explores optimal undersampling trajectory for DeepLearnMRI. Specifically, we designed hamming filtered asymmetrical 1D partial Fourier sampling scheme for fast MR imaging with our developed super-resolution convolutional neural network. Experimental results on in vivo dataset show that the proposed scheme allows DeepLearnMRI to reconstruct more accurate MR images with less time compared to the Classical GRAPPA and SPIRiT.

[Feasibility of Multi-contrast MR imaging via deep learning](#)

Shanshan Wang¹, Tao Zhao^{1,2}, Ningbo Huang^{1,3}, Sha Tan^{1,4}, Yuanyuan Liu¹, Leslie Ying⁵, and Dong Liang¹

¹Paul C. Lauterbur Research Center for Biomedical Imaging, SIAT, Chinese Academy of Sciences, Shenzhen, People's Republic of China, ²College of Mining and Safety Engineering, Shandong University of Science and Technology, Qingdao, People's Republic of China, ³School of Computer Science and Technology, Changchun University of Science and Technology, Changchun, People's Republic of China, ⁴School of Information Engineering, Guangdong University of Technology, Guangzhou, People's Republic of China, ⁵Department of Biomedical Engineering and Department of Electrical Engineering, The State University of New York, NY, United States

This paper develops a deep learning based multi-contrast MR imaging method. Unlike existing methods which mainly draw prior information from the target structure or a few reference images, we design a multi-contrast convolutional neural network to draw automatic feature descriptors for describing the multi-contrast correlations and identify the nonlinear mapping with the utilization of enormous existing multi-contrast MR images as training samples. Once the network is learned, it performs as a predictor for the online multi-contrast MR imaging. Experimental results on multi-contrast in vivo dataset show that the proposed method could restore lost information from the undersampled MR images while keeping their contrasts.

Magnetic resonance imaging (MRI) of bones has added value for fracture risk assessment in osteoporosis, a disease of weak bones. However, manual segmentation of bone images is time-intensive, causing slow throughput for test results and inefficient risk assessment for patients. In this work, we implemented an automatic proximal femur segmentation algorithm by modeling a convolutional neural network (CNN) as a pixel-wise binary classification. The accuracy of automatic segmentation was investigated by analyzing similarity between automatic and manual ground-truth segmentation. In addition, we compared the time required for manual fine-tuning of the CNN segmentation with original manual segmentation.

[Performance comparison of artificial neural network and fuzzy deep learning algorithms for respiratory motion prediction in pseudocontinuous arterial spin labeling of the abdomen](#)

H Michael Gach¹, Hao Song², Seonyeong Park³, Yuichi Motai³, Dan Ruan⁴, Wenyang Liu⁴, V Andrew Stenger⁵, Rolf Pohmann⁶, and Jingqin Luo⁷

¹Radiation Oncology and Radiology, Washington University in St Louis, St Louis, MO, United States, ²Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston, TX, United States, ³Electrical and Computer Engineering, Virginia Commonwealth University, Richmond, VA, United States, ⁴Radiation Oncology, University of California Los Angeles, Los Angeles, CA, United States, ⁵Medicine, University of Hawai'i at Manoa, Honolulu, HI, United States, ⁶High-Field Magnetic Resonance Center, Max Planck Institute for Biological Cybernetics, Tubingen, Germany, ⁷Biostatistics and Medicine, Washington University in St Louis, St Louis, MO, United States

Subtraction-based imaging methods like pseudocontinuous arterial spin labeling (pCASL) in the body are challenging due to physiological motion. Respiratory motion prediction (RMP) using an artificial neural network (ANN) and pencil beam navigators was previously integrated into a pCASL sequence to permit free-breathing perfusion MRI of the kidney. In an effort to improve the accuracy of the RMP, we compared the performance of a promising fuzzy deep learning (FDL) algorithm with ANN using navigator-echo displacements recorded from 8 volunteers during pCASL. FDL combines ANN with fuzzy logic. However, the ANN performance was significantly better than FDL for the pCASL application.

[A Study of Simulated Training Data for Image Reconstruction from Subsampled MR Data using Artificial Neural Network](#)

kinam kwon¹, Jaejin Cho¹, Seohee So¹, Byungjai Kim¹, Yoonmee Lee¹, kyungtak Min¹, and HyunWook Park¹

¹KAIST, Daejeon, Korea, Republic of

Recently, several works have applied the deep learning technique to medical imaging problems such as lesion classification and image reconstruction. The deep learning techniques have advantages of learning from big data, however, in medical imaging, collecting an amount of training data is not easy because of expense, privacy, and so on. Strategies to supplement insufficient training data are important topics for applying deep learning to medical imaging field. In this study, training data are generated from the simulated images and the acquired MR images, which are utilized to learn the architecture of multilayer perceptron to reduce imaging time.

[Machine-learning-based treatment response stratification for trans-arterial chemoembolization in HCC patients.](#)

Atilla Peter Kiraly¹, Robert Grimm², Mounes Aliyari Ghasebeh³, Li Pan⁴, David Liu¹, Berthold Kiefer², and Ihab Roushdy Kamel³

¹Medical Imaging Technologies, Siemens Medical Solutions USA, Princeton, NJ, United States, ²MR Application Predevelopment, Siemens Healthcare, Erlangen, Germany, ³The Russell H. Morgan Department of Radiology and Radiological Sciences, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ⁴Siemens Healthcare, Baltimore, MD, United States

In determining the effectiveness of chemoembolization in HCC, functional MRI has been shown to differentiate responders and non-responders earlier than anatomical measurements such as RECIST or EASL criteria. In previous studies, multiparametric response criteria based on thresholds of changes in ADC and venous enhancement (VE) intensities were proposed. We present improved stratification based on machine learning and image-based features. On a set of 57 chemoembolization patients, the proposed approach achieved a mean classification accuracy of 84% versus 66% for the previous threshold-based approach. These results further demonstrate the incremental value of functional MRI over traditional anatomical measures.

[A Machine Learning Based Approach for Fast T1 estimation with Improved Accuracy](#)

Anirban Sengupta¹, Rakesh Kumar Gupta², Sumeet Agarwal³, and Anup Singh⁴

¹CBME, IIT Delhi, New Delhi, India, ²Radiology Department, FORTIS hospital, Gurgaon, India, ³Electrical Engineering, IIT Delhi, India, ⁴Centre for Biomedical Engineering, IIT Delhi; AIIMS Delhi, New Delhi, India

The purpose of this study is to propose a fast T1 estimation method with improved accuracy over existing approaches in a Multiple Flip Angle setting. A supervised machine learning based approach has been proposed that can be used to predict additional Flip Angle data using limited available Flip Angle data, thereby producing more accurate T1 estimation in reduced scan time. Both experimental as well as simulation results are shown to illustrate the efficacy of this approach. The accuracy of T1 estimation depends on the choice of Flip Angle data to be predicted.

Application of Random Forest Regression for Fast and Robust MRF Dictionary Matching

Shivaprasad Ashok Chikop¹, Vimal Chandran², Imam Shaik¹, Mauricio Antonio Reyes Aguirre², and Sairam Geethanath¹¹Medical Imaging Research Centre, Dayananda Sagar Institutions, Bangalore, India, ²Institute of Surgical Technology and Biomechanics, University of Bern, Bern, Switzerland

Magnetic Resonance Fingerprinting (MRF) provides for simultaneous generation of MR multi-parametric maps from a single acquisition. In this work, a machine learning based regression method that does not require a dictionary has been demonstrated. A leave-one-out evaluation strategy was employed for numerical evaluation of the proposed MRF-RF approach. A comparative study was performed on two previously employed matching methods. Results depict that proposed MRF-RF method produces maps similar to the vector dot product approach, with a 10-fold saving in time. The method can also be extended to other non-linear maps such as B0 inhomogeneity, diffusion maps, and perfusion maps.

High-Resolution DWI Using Multishot Variable Density Spiral with SPIRiT-Based Reconstruction

Zijing Dong¹, Xiaodong Ma¹, Fuyixue Wang^{1,2}, Chun Yuan^{1,3}, and Hua Guo¹¹Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China, ²Harvard-MIT Health Sciences and Technology, MIT, Cambridge, MA, United States, ³Vascular Imaging Laboratory, Department of Radiology, University of Washington, Seattle, WA, United States

Multishot variable density spiral is an efficient sequence for diffusion imaging with the oversampled k-space center serving as a navigator. However, the shot-to-shot phase variation of multishot acquisition due to motion must be corrected. To improve the reconstruction accuracy, we propose a novel reconstruction framework using SPIRiT-based reconstruction, integrating the information of phase variation and coil sensitivity in order to correct for the ghosting artifacts of multi-shot DWI. Both simulation and in-vivo experiment validated the superior performance of the proposed method to reconstruct more accurate images than CG-SENSE for VDS DWI.

Golden-Ratio Rotated Stack-of-Stars Acquisition for Improved Volumetric MRI

Ziwu Zhou¹, Fei Han¹, Lirong Yan², Danny J.J. Wang², and Peng Hu¹¹Radiological Sciences, University of California, Los Angeles, Los Angeles, CA, United States, ²Neurology, University of Southern California, Los Angeles, CA, United States

In this abstract, we developed and evaluated an improved stack-of-stars (SOS) sampling strategy that can efficiently sample 3D k-space and reduce streaking artifacts. Compared with conventional SOS sampling strategies that collect the same radial angle for every slice, proposed method rotates the spokes in a golden-angle manner along the slice direction, which modifies the aliasing pattern resulted from k-space under-sampling. With either gridding reconstruction or more advanced methods, proposed rotated SOS sampling strategy provides improved image quality with reduced streaking artifacts and better delineation of fine structures.

Unstreaking: Radial MRI with Automatic Streaking Artifact Reduction

Li Feng¹, Hersh Chandarana¹, Daniel K Sodickson¹, and Ricardo Otazo¹

¹Center for Advanced Imaging Innovation and Research (CAI2R), New York University School of Medicine, New York, NY, United States

Streaking artifact is one of the major causes of image quality degradation in radial MRI. Since multicoil arrays are widely used in modern MR scanners, an easy way to reduce streaking artifacts is to identify coil elements that are contaminated by a high level of streaks, and then exclude them from image reconstruction. However, such an approach requires accurate clustering algorithms to automatically select unwanted coil elements. In this work, a method called "Unstreaking" is proposed for automatic streaking artifact reduction without the need to exclude coil elements. The method was tested for accelerated radial DCE-MRI of the liver.

Computer 54

Rapid Two-Step 2D Filtered Backprojection for 3D radial-data reconstruction: Comparison of computational times with conventional methods

JeongTaek Lee^{1,2}, Seung-Kyun Lee^{1,2}, Jinil Park^{1,2}, and Jang-Yeon Park^{1,2}

¹Center for Neuroscience Imaging Research, Institute for Basic Science (IBS), Suwon, Korea, Republic of, ²Department of Biomedical Engineering, Sungkyunkwan University (SKKU), Suwon, Korea, Republic of

3D-FFT via gridding is generally recognized as computationally faster than direct 3D filtered backprojection (FBP) in 3D radial-data reconstruction. To overcome the computational time issue of 3D-FBP, we investigated two-step 2D-FBP reconstruction having an alternative k-space trajectory. Computational requirements were theoretically analyzed to permit clear comparison among three reconstruction methods and computational burdens based on mathematical expressions were compared to actual computation times. In conclusion, two-step FBP provides considerable computational speed benefit over direct 3D-FBP and, under certain realistic conditions (e.g., with many channels), even over 3D-FFT, while showing almost same image quality in phantom and brain imaging.

Comparison of Sequential and Joint Methods for Spiral Water-fat Separation and Deblurring

Dinghui Wang¹ and James G. Pipe¹

¹Imaging research, Barrow Neurological Institute, Phoenix, AZ, United States

Most previous approaches to spiral water-fat imaging perform the water-fat separation and deblurring sequentially based on the assumption that the phase accumulation and blurring are separable. A joint water-fat separation and deblurring method has been recently proposed using more accurate signal models. In this study, the sequential and joint methods are quantitatively compared. Simulation and experiments have demonstrated that the results of the joint method are significantly better in regions where the field inhomogeneity changes rapidly in space. The loss of signal-to-noise-ratio is minor for both approaches at optimal TEs when the noise in the field map Δf_0 is negligible.

¹GE Global Research Europe, Garching bei München, Germany, ²Cardiac Center of Excellence, GE Healthcare, Garching bei München, Germany, ³GE Healthcare, Menlo Park, CA, United States, ⁴GE Healthcare, Waukesha, WI, United States
- Radial cardiac real-time datasets are usually compromised by streaking artifacts. Truncated principal component analysis (PCA) has been proposed to remove streaking and improve apparent SNR of the images. However, a proper threshold for truncation of the PCA has to be selected to maintain good temporal fidelity. This work proposes a method for automatic truncation of the PCA and compares a soft against the standard hard thresholding approach. Results indicate that the proposed method in combination with soft thresholding offers reduced temporal blurring and streaking artifacts while improving apparent SNR.

Evaluation of Rapid Radial Imaging Methods for Assessment of First Pass Myocardial Perfusion

James J Pilla¹, Gamaliel Isaac¹, Joseph H Gorman III¹, Robert C Gorman¹, and Lawrence Dougherty¹¹University of Pennsylvania, Philadelphia, PA, United States

Rapid image acquisition is required to assess myocardial first-pass perfusion. K-t CS which uses compressed sensing has produced dynamic images with sufficient resolution. View sharing methods such as k-t VS could potentially provide similar results eliminating the need for regularization weights and significantly decreasing reconstruction time. K-t CS and k-t VS were investigated to determine their temporal and spatial response during first-pass myocardial perfusion. Results demonstrate that images reconstructed using each method had similar resolution and showed good correlation in assessing uptake kinetics. However, at higher acceleration, k-t CS showed increased SNR and smoother appearance while k-t VS used a less computationally intense and faster reconstruction.

Variable-blipped-EPI (VB-EPI) for Lower Acoustic Noise and Higher Efficiency with non-Cartesian iterative Reconstruction

Patrick Liebig^{1,2}, Robin Martin Heidemann², Bernhard Hense¹, and David Porter³¹University of Erlangen-Nuremberg, Erlangen, Germany, ²Siemens Healthcare GmbH, ³Fraunhofer MEVIS

Echo-Planar-Imaging¹ (EPI) with trapezoidal Readout (RO) and blipped Phase-Encoding (PE) gradients gives a high level of acoustic noise². To reduce acoustic noise we suggest prolonging the duration of the blipped PE gradient in combination with a sinusoidal or trapezoidal RO gradient and continuous data sampling throughout the whole RO train. This results in a variable density sampling along PE (less dense at the edges, denser in the centre of k-space) with a non-Cartesian trajectory, where we use ESPIRiT³ to reconstruct the data. The efficiency is improved due to continuous data sampling, resulting also in a reduced echo time.

4015

Computer 66

Partial Fourier Shells Trajectory with Non-Iterative Homodyne Reconstruction

Shengzhen Tao¹, Yunhong Shu¹, Joshua D Trzasko¹, Paul T Weavers¹, Erin M Gray¹, John Huston III¹, and Matt A Bernstein¹¹Radiology, Mayo Clinic, Rochester, MN, United States

The 3D Shells trajectory-based MRI acquisition is a non-Cartesian acquisition technique that divides the 3D k-space into a series of concentric shells and samples each one with 3D helical readouts. Using the Shells trajectory, the inner k-space can be efficiently sampled within several interleaves, making it a maximally centric 3D acquisition. Partial Fourier (PF) acquisition is a commonly-used acceleration technique by exploiting the conjugate symmetry of k-space measurement. In this work, we present a new asymmetric 3D Shells trajectory design with PF acceleration to combine the advantages from both techniques, and develop a non-iterative homodyne reconstruction framework for it.

4016

Computer 67

Spherical-surface Poisson disc point selection for radial-trajectory MRI

Ethan M Johnson¹, Kim Butts Pauly², and John M Pauly¹¹Electrical Engineering, Stanford University, Stanford, CA, United States, ²Radiology, Stanford University, Stanford, CA, United States

A design consideration for center-out k -space trajectories is the angular distribution of trajectory endpoints (or equivalently, exit angles). Uniformity is desirable, but the regularity of spacing affects aliasing patterns, which can dictate undersampling performance. Here, a method for choosing points on a sphere with Poisson disc spacing is described, and its use in selecting angles for a 3D radial UTE sequence is validated.

Computer 68

Correction of dynamic off-resonance in spiral 2D real-time MRI of speech

Yongwan Lim¹, Sajan Goud Lingala¹, Shrikanth Narayanan¹, and Krishna Nayak¹¹Ming Hsieh Department of Electrical Engineering, University of Southern California, Los Angeles, CA, United States

Spiral real-time MRI (RT-MRI) is a valuable tool in speech production research. A key drawback is off-resonance blurring artifact that appears at the boundaries of important articulators. In this work, we demonstrate dynamic off-resonance estimation that is directly captured from phase of single echo-time dynamic images after coil phase compensation. Multi-frequency reconstruction then provides deblurring and improved depiction of articulator boundaries including the tongue, hard palate, and soft palate.

4018

Computer 69

Sliding Slice 2D Spiral Time of Flight MRA

Nicholas R. Zwart¹ and James G. Pipe¹¹MR Technology Design Group, Barrow Neurological Institute, Phoenix, AZ, United States

The scan technique and reconstruction method presented in this work are designed to reduce the scan duration of 2D time-of-flight angiography sequences. The acquisition makes use of a sliding-slice technique that eliminates the need for steady-state prep pulses, which are needed before each slice in time-of-flight. This reduces the total scan time of a 2D spiral time-of-flight sequence by almost half, without a reduction in k -space coverage.

Computer 70

Spiral MPRAGE Acquisition and Segmentation

Kyoko Fujimoto^{1,2}, Brian R. Keating², and V. Andrew Stenger^{1,2}¹Department of Electrical Engineering, University of Hawaii at Manoa, Honolulu, HI, United States, ²Department of Medicine, John A. Burns School of Medicine, University of Hawaii, Honolulu, HI, United States

High-resolution MPRAGE has become a standard structural imaging sequence in clinical settings yet it is difficult to repeat the scan because of its relatively long acquisition time. Acceleration techniques allow the reduction of acquisition times although excessive acceleration can result in artifacts. We implemented a fast MPRAGE sequence using a spiral trajectory and demonstrated segmentation of acquired images. The spiral MPRAGE can acquire a whole-brain T₁ volume in less than 25% of the acquisition time of the conventional MPRAGE while maintaining comparable contrast and segmentation results.

Computer 71

A Two-Dimensional Spiral Turbo-Spin-Echo Technique with T₂-delay Correction and Concomitant Phase Compensation

Zhiqiang Li¹, Dinghui Wang¹, Ryan K Robison¹, John P Karis², and James G Pipe¹

¹Imaging Research, Barrow Neurological Institute, Phoenix, AZ, United States, ²Neuroradiology, Barrow Neurological Institute, Phoenix, AZ, United States

Turbo spin-echo (TSE) is a rapid technique routinely used for T₂ and FLAIR imaging. Two-dimensional spiral TSE is very challenging due to T₂ signal decay. In this project we develop a 2D spiral TSE sequence employing a spiral-in/out readout for efficient acquisition without off-resonance phase errors, and a double encoding mechanism as well as signal demodulation to minimize T₂ signal decay induced artifacts. A concomitant phase compensation technique is incorporated to mitigate the violation of the CPMG condition. Preliminary spiral TSE FLAIR results demonstrate comparable image quality to its Cartesian counterpart.

4021

Computer 72

Spiral keyhole imaging for MR fingerprinting

Guido Buonincontri¹, Laura Biagi^{1,2}, Pedro A Gómez^{3,4}, Rolf F Schulte⁴, and Michela Tosetti^{1,2}

¹IMAGO7 Research Center, Pisa, Italy, ²IRCCS Stella Maris, Pisa, Italy, Pisa, Italy, ³Technische Universität München, Munich, Germany, ⁴GE Global Research, Munich, Germany

MR Fingerprinting can be used for a fast and quantitative estimation of physical parameters in MRI. For the fast acquisition of MRF, common approaches have used non-Cartesian sampling of k-space. Here, we introduce a method for non-iterative anti-aliasing of the spiral MRF time series, based on the concept of keyhole imaging. Our approach does not change acquisition or dictionary creation and matching procedures. As frames require only minimal density compensation in k-space, noise amplification during reconstruction is reduced. After applying our algorithm, individual images from the MRF time series are artifact-free and clearer parameter maps are obtained in a shorter time while preserving the accurate quantification of MRF.

2D Zero TE Imaging Implemented with Gradient-Extended 2D Spiral-in Excitation and Spiral-out Acquisition (GRESS-ZTE)

Qing Li¹, Xiaozhi Cao¹, Congyu Liao¹, Hongjian He¹, and Jianhui Zhong¹

¹Center for Brain Imaging Science and Technology, Department of Biomedical Engineering, Zhejiang University, Hangzhou, Zhejiang, People's Republic of China

A 2D zero TE imaging technique was implemented with a gradient-extended 2D spiral-in excitation to excite a slice within 3mm full-width-half-maximum (FWHM) with pulse duration less than 6ms and spiral-out acquisition (GRESS-ZTE) strategy. Our preliminary data showed its ability to acquire signals in bones with very short T₂*

4023

Computer 98

High resolution dual-echo subtraction ZTE imaging at 7T with TE estimation based on multiple scaled trajectories

Hyo Min Lee¹, Markus Weiger¹, and Klaas Paul Pruessmann¹

¹Institute for Biomedical Engineering, University and ETH Zürich, Zürich, Switzerland

In dual-echo subtraction ZTE (DE-ZTE) MRI, it is crucial to correct for gradient delays in the second echo for high image quality. Linear phase fitting on the relative phase difference between projection pairs in image domain can be performed to estimate TE shifts, but it is not highly robust. Field camera can be used to externally provide TE shifts arising from gradient delays, but the probes tend to dephase at high resolution DE-ZTE scans. We demonstrate that gradient delays can be characterized as a linear function of gradient strength. Furthermore, we show that this can be exploited to reconstruct high resolution DE-ZTE data at 7T for high image quality.

Computer 99

Ultra-short Echo-time MRI Lung Segmentation using High-Dimensional Features and Continuous Max-Flow

Fumin Guo¹, Khadija Sheikh¹, Robert Peters², Michael Carl², Aaron Fenster¹, and Grace Parraga¹

¹Robarts Research Institute, London, ON, Canada, ²General Electric Healthcare, Milwaukee, WI, United States

Ultra-short-echo-time MRI may be used to generate imaging biomarkers to phenotype pulmonary abnormalities and facilitate the development of novel treatments but requires clinically-acceptable lung segmentation. We proposed an adaptive kernel K-means approach combining MRI signal intensity and neighbourhood location information for optimized lung segmentation. The resultant high dimensional features were implemented using a K-nearest neighbour graph and relaxed to a point-wise upper-bound formulation regularized by image edge information, which was implemented iteratively using a continuous max-flow optimization approach. Experimental results for 10 asthmatics demonstrated highly accurate, reproducible and computationally efficient lung segmentation for our approach consistent with clinical workflows.

4025

Computer 100 Whole-Body, Zero TE Based Pseudo CT Conversion

Florian Wiesinger¹, Sangtae Ahn², Sandeep Kaushik³, Cristina Cozzini¹, Dirk Beque¹, Lishui Cheng², Jaewon Yang⁴, Andrew Leynes⁴, Dattesh Shanbhag³, Thomas A. Hope⁴, and Peder E. Z. Larson⁴

¹GE Global Research, Munich, Germany, ²GE Global Research, Schenectady, NY, United States, ³GE Global Research, Bangalore, India, ⁴Radiology and Biomedical Imaging, UCSF, San Francisco, CA, United States

Proton density (PD) weighted Zero TE (ZTE) MR imaging has been demonstrated to provide accurate bone depiction, segmentation and pseudo CT conversion in the head. However, when applied for the whole-body, discriminating between air and bone appears challenging (primarily because of SNR and RF shading). Here we present a novel method for decomposition of low ZTE signal intensity regions into bone and air based on connected component and shape analysis. The method is demonstrated for whole-body, pseudo CT conversion in three PET/MR patients.

4026

Computer 101 Accelerated Adaptive Quasi-Random Single-Point Imaging for in vivo Artefact Reduction

Tobias Speidel¹ and Volker Rasche²

¹Core Facility Small Animal Imaging, University of Ulm, Ulm, Germany, ²Department of Internal Medicine II, University of Ulm, Ulm, Germany

MR imaging of short relaxation times spin systems has been a widely discussed topic with serious clinical applications and led to the emergence of fast imaging ultra-short echo-time sequences such as UTE and ZTE. Nevertheless, these sequences suffer from image blurring due to the related point-spread function and are highly prone to imaging artefacts arising from e.g. chemical shifts or magnetic susceptibilities. In this work, we present a fully functional concept of spherical quasi-random single-point imaging that is highly acceleratable due to intrinsic undersampling properties and capable of strong metal artefact suppression with high tissue contrast.

4027

Computer 102 The Value of Ultrashort-Echo-Time (UTE) MR in Depiction of the Eustachian Tube at 3 Tesla

Wu Chao¹, Qian Tianyi², Wang Guangbin¹, Li Li³, Wang Yuyu⁴, Shi Honglu¹, Gao Fei¹, and Zhao Bin¹

¹Shandong Medical Imaging Research Institute, Shandong University, Jinan, People's Republic of China, ²MR Collaborations NE Asia, Siemens Healthcare, ³Shandong Provincial Hospital Affiliated with Shandong University, ⁴Siemens Shenzhen Magnetic Resonance Ltd., Shenzhen, People's Republic of China

This study aimed to investigate the feasibility of ultrashort echo time (UTE) in visualizing the Eustachian tube (ET). Nineteen healthy volunteers were involved in this study. The quality of images was rated by two experienced radiologists using a double-blind method. Using the depiction of the cartilaginous part of the ET from standard T2-weighted images and that of the bony part from CT acquisition as reference points, UTE images were analyzed. The results indicate that UTE can not only display ET cartilage, but also display bone structure. This could lead to the application of whole-ET imaging in one MR exam.

4028

Computer 103 2D-UTE based pantomography with half-pulse excitation

Kilian Stumpf¹, Elena Kaye², Jan Paul¹, Stefan Wundrak³, and Volker Rasche¹

¹Internal Medicine II, University Hospital of Ulm, Ulm, Germany, ²Department of Medical Physics, Memorial Sloan Kettering Cancer Center, New York, NY, United States, ³Dental Imaging, Sirona Dental Systems GmbH, Bensheim, Germany

Standard imaging methods in dental radiology are almost exclusively based on X-rays. Not only does magnetic resonance imaging (MRI) avoid ionizing radiation, but has also been shown to be superior in identifying carious lesions. In this work we present a 2D-UTE sequence with an echo time of 35µs, utilizing 240µs half-pulses to ensure reduced signal attenuation from tissues with short T2 relaxation during excitation. The feasibility of the method was demonstrated with the successful acquisition of in vivo MR pantomograms.

4029

Computer 104 An Iterative Gradient Delay Correction Method for 3D UTE Imaging

Qi Liu¹, Xiaomao Gong², Xiaolei Guan², Xueming Cao², Lingzhi Hu¹, Xiaodong Zhou², Jian Xu¹, and Weiguo Zhang²

¹UIH America, Inc., Houston, TX, United States, ²Shanghai United Imaging Healthcare Co., Ltd., Shanghai, People's Republic of China

Gradient imperfections such as gradient delay can cause image distortion and artifacts in UTE imaging. In this work, we report an iterative gradient delay correction method for 3D UTE imaging that allows use of arbitrary gradient waveform model, independent calibration of x, y, and z gradients, and subject-specific delay correction with an embedded prescan. The feasibility of improved image quality using this proposed method was demonstrated by volunteer data.

4030

Computer 105 Myelin and cortical bone short-T2 quantification using saturation and diffusion-based long-T2 suppression in a steady-state 3D-UTE sequence

Lucas Soustelle¹, Paulo Loureiro de Sousa¹, Julien Lamy¹, Mathieu D. Santin², François Rousseau³, and Jean-Paul Armspach¹

¹Université de Strasbourg, CNRS, ICube, FMTS, Strasbourg, France, ²ICM, CENIR, UPMC-Inserm U1127, CNRS 7225, Paris, France, ³Institut Mines Télécom, Télécom Bretagne, INSERM LaTIM, Brest, France

Imaging of the very-short T_2 tissues in the head is challenging in that the signals decay very rapidly ($T_2 < 1$ ms), as well as their signal quantity being often overwhelmed by long- T_2 relaxing components (fat, free-water). In this work, we explore the feasibility of short- T_2 quantification in the white matter and in the cortical bone using a novel method for long- T_2 suppression based on diffusion and coherence effects in a steady-state 3D-UTE sequence.

4031

Computer 106

Long- T_2 suppression based on saturation and diffusion in a steady-state 3D-UTE sequence

Lucas Soustelle¹, Julien Lamy¹, Paulo Loureiro de Sousa¹, François Rousseau², and Jean-Paul Armspach¹

¹Université de Strasbourg, CNRS, ICube, FMTS, Strasbourg, France, ²Institut Mines Télécom, Télécom Bretagne, INSERM LaTIM, Brest, France

A new method for long- T_2 suppression in a prepared steady-state 3D-UTE sequence is introduced. The method is based on long- T_2 signal behavior in steady-state as the diffusion-inducing spoiling gradients are modified, giving a theoretical signal cancellation using appropriate coherence combinations. At the same time, short- T_2 signal quantity is optimized, offering a positive contrast over this component. Imaging experiments over a Lego brick soaked in doped water show an excellent agreement with theoretical predictions.

4032

Computer 107

Inversion-non-Recovery (InoR) method for long- T_2 suppression in a steady-state 3D-UTE sequence for short- T_2 imaging

Lucas Soustelle¹, Julien Lamy¹, Paulo Loureiro de Sousa¹, François Rousseau², and Jean-Paul Armspach¹

¹Université de Strasbourg, CNRS, ICube, FMTS, Strasbourg, France, ²Institut Mines Télécom, Télécom Bretagne, INSERM LaTIM, Brest, France

A novel method for long- T_2 suppression in 3D-UTE imaging is introduced. The method is based on long- and short- T_2 components phase states in a dual-segment acquisition scheme (digital summation of two k-spaces before reconstruction, respectively acquired with and without adiabatic inversion), and offers a substantial contrast-to-noise ratio over the different components. We compare our method to the state-of-the-art IR-UTE. It shows higher performance and efficiency in terms of signal suppression and short- T_2 contrast.

4033

Computer 108

MR-embedded respiratory motion tracking in ZTE lung imaging for PET-MRI

Tanguy Boucneau¹, Brice Fernandez², Michael Soussan³, Luc Darrasse¹, and Xavier Maître¹

¹Imagerie par Résonance Magnétique Médicale et Multi-Modalités, IR4M, CNRS, Univ Paris-Sud, Université Paris-Saclay, Orsay, France, ²Applications & Workflow, GE Healthcare, Orsay, France, ³Imagerie Moléculaire in Vivo, IMIV, Inserm, CEA, CNRS, Univ Paris-Sud, Université Paris-Saclay, Orsay, France

This study aims at showing the feasibility of MR-embedded respiratory motion tracking in ZTE lung imaging. It was shown that the motion information in a moving phantom as well as in free-breathing human volunteers and patients could be extracted from the off-center k-space data sampled during a ZTE acquisition with a faithful accuracy and precision in time and in amplitude with respect to a respiratory belt measurement. This new intrinsic motion follow-up method could be useful for retrospective motion correction of simultaneously acquired PET/MR images.

4034

Computer 109

Influence of k-space trajectory corrections on the proton density mapping precision with Ultrashort Echo Time Imaging.

Peter Latta¹, Zenon Starčuk², Marco Gruwel³, and Boguslaw Tomaneck^{1,4}

¹Central European Institute of Technology, Masaryk University, Brno, Czech Republic, ²Institute of Scientific Instruments, Academy of Sciences of the Czech Republic, Brno, Czech Republic, ³Biological Resources Imaging Laboratory, Lowy Cancer Research Centre, Sydney, Australia, ⁴University of Alberta, Edmonton, Canada

The ultrashort echo time (UTE) sequence is capable to provide information about tissues with short T_2 . On the other hand, as with all non-Cartesian data sampling schemes in general, it is sensitive to mismatching in the acquisition trajectory. This can be a potential source of errors, especially when used for quantitative applications such as proton density (PD) mapping. This problem can be reduced by calibration and correction of the k-space acquisition trajectories. The presented experiments demonstrate the importance of sampling trajectory corrections for UTE imaging, especially when applied for quantitative measurements.

4035

Computer 110

Fast, Volumetric and Silent Multi-contrast Zero Echo Time Imaging

Xin Liu^{1,2}, Pedro Gómez^{1,2}, Tim Sprenger^{1,2}, Ana Beatriz Solana², Florian Wiesinger², Marion Menzel², Jonathan Sperl², and Bjoern Menze¹

¹Technical University Munich, Garching, Germany, ²GE Global Research, Garching, Germany

The current work aims to provide a volumetric, fast and silent method for quantitative T_1 mapping with Zero Echo Time (ZTE) imaging, and generate multiple T_1 -weighted images at virtual inversion times. By designing an interleaved radial trajectory for ZTE, and constraining the temporal behavior of the signal with low-dimensional subspace and spatiotemporal low rank regularization, we conducted a volumetric T_1 mapping in 2 minutes with acoustic noise only 1.1dB higher than scanner background.

4036

Computer 111

A new ultrafast 3D gradient-echo magnetic resonance imaging method: RASE-I

Jaekyun Ryu^{1,2}, SoHyun Han^{1,2}, Joon-sung Lee^{1,2}, Seong-gi Kim^{1,2}, and Jang-Yeon Park^{1,2}

¹Center for Neuroscience Imaging Research, Institute for Basic Science (IBS), Suwon, Korea, Republic of, ²Department of Biomedical Engineering Sungkyunkwan University (SKKU), Suwon, Korea, Republic of

One version of a new ultrafast *gradient-echo-based* 3D imaging technique using spatiotemporal encoding (RASE-I) is proposed which can provide very short TEs in some slices. RASE-I maintains most of appealing features of other *spin-echo-based* SPEN imaging methods including no Nyquist ghosting and high tolerance to field inhomogeneities. It is barely affected by T_2^* signal modulation and less sensitive to T_2^* effects due to local rephasing mechanism along the SPEN direction. Its performance is demonstrated by lemon and in-vivo mouse kidney imaging at 9.4T, including the measurement of dose-dependent arterial-input-function (AIF) of kidney-feeding artery.

4037

Computer 112 Ultra-high-bandwidth, high-resolution MRI of fast relaxing spins

Romain Nicolas Froidevaux¹, Markus Weiger¹, Manuela B. Rosler¹, Bertram Wilm¹, Franciszek Hennel¹, Roger Luechinger¹, Benjamin Dietrich¹, Jonas Reber¹, and Klaas Paul Pruessmann¹

¹University and ETH Zurich, Zürich, Switzerland

High resolution MRI of fast relaxing spins in human sets strong requirements on hardware and pulse sequences. Indeed, the acquisition duration is limited by the relaxation time of the protons of interest and high resolution can only be achieved with large magnetic field gradients. Also when large field-of-view is required, additional challenges appear. The sequence and receive hardware needs to be adapted to larger bandwidth. In this work, we image short T2 compounds in human scanners with gradient strengths up to 200 mT/m and bandwidth up to 1.63 MHz.

4038

Computer 113 Utilization of T1pMR imaging in Sjögren's syndrome with normal appearing parotid glands: initial findings

Zhengyang Zhou¹, huayong zhang², and Weibo Chen³

¹Department of Radiology, Drum Tower Hospital, School of Medicine, Nanjing University, Nanjing, People's Republic of China, ²Department of Rheumatology, Drum Tower Hospital, School of Medicine, Nanjing University, People's Republic of China, ³Philips Healthcare, Shanghai, People's Republic of China

Sixteen SS patients and age- and gender- match healthy volunteers underwent parotid MR imaging to evaluate whether T1p values could diagnose of SS patients. T1p values between the patients and healthy volunteers were compared. ROC analysis was used to evaluate the diagnostic performance of the T1p values. The T1p values of SS patients were significantly higher than those of healthy volunteers. With a cutoff value of 88.02 ms, the diagnostic sensitivity and specificity of the parotid T1p value was 75.0% and 100.0%, respectively. Parotid T1p MR imaging held the potential in the diagnosis of SS without morphological changes of glands.

4039

Computer 114 Human In-vivo MR Current Density Imaging (MRCDI) Based on Optimized Multi-echo Spin Echo (MESE)

Cihan Göksu^{1,2}, Lars Grüner Hanson^{1,2}, Philipp Ehses^{3,4}, Klaus Scheffler^{3,4}, and Axel Thielscher^{1,2,3}

¹Center for Magnetic Resonance, DTU Elektro, Technical University of Denmark, Kgs. Lyngby, Denmark, ²Danish Research Centre for Magnetic Resonance, Centre for Functional and Diagnostic Imaging and Research, Copenhagen University Hospital, Hvidovre, Denmark, ³High-Field Magnetic Resonance Center, Max-Planck-Institute for Biological Cybernetics, Tübingen, Germany, ⁴Department of Biomedical Magnetic Resonance, University of Tübingen, Tübingen, Germany

MRCDI aims at imaging an externally injected current flow in the human body, and might be useful for many biomedical applications. However, the method requires very sensitive measurement of the current-induced magnetic field component $\Delta B_{z,c}$ parallel to main field. We systematically optimized MESE to determine its most efficient parameters. In one of the first human in-vivo applications of MRCDI, the optimized sequence was successfully used to image the $\Delta B_{z,c}$ distribution in the brain caused by a two-electrode montage, as confirmed by finite-element calculations of $\Delta B_{z,c}$. Further improvements will be performed to increase its robustness to field drifts.

4040

Computer 115 Tissue Relaxometry Defined (TRD) pseudo-CT imaging based on a single multi-gradient-echo MRI scan

Jie Wen¹, Bin Cai², Michael Gach², Olga Green², Christina Tsien², Jiayi Huang², Sasa Mutic², and Dmitriy Yablonskiy¹

¹Radiology, Washington University in St. Louis, St. Louis, MO, United States, ²Radiation Oncology, Washington University in St. Louis, St. Louis, MO, United States

Generating MRI-based pseudo-CT images, providing electron density information for dose calculation, is the first step towards MRI-based radiation therapy treatment planning. Existing methods either require prior knowledge of a CT-MR atlas or require acquisition of multiple scans. In this study, we demonstrated the feasibility of producing pseudo-CT images by using a single multi-gradient-echo sequence. This method takes advantage of tissue-specific relaxation properties of MRI signal to provided segmentation of bone, air and other anatomical structures. Since all images are generated from a single scan and are naturally co-registered, this method is fast and avoids registration errors.

4041

Computer 116 Multi-compartment T2 relaxometry Model using Gamma Distribution representations: A framework for Quantitative Estimation of Brain Tissue Microstructures.

Sudhanya Chatterjee¹, Olivier Commowick², Simon K. Warfield³, and Christian Barillot⁴

¹VisAGeS, IRISA U746, Universite de Rennes-1, Rennes, France, ²VisAGeS Inserm U746, IRISA, Inria, Rennes, France, ³Boston Children's Hospital, Boston, MA, United States, ⁴VisAGeS, INRIA/IRISA, Inserm U746, CNRS, Rennes, France

Advanced MRI techniques (e.g. - d-MRI, MT, relaxometry etc.) can provide quantitative information of brain tissues. Image voxels are often heterogeneous in terms of microstructure information due to physical limitations and imaging resolution. Quantitative assessment of the brain tissue microstructure can provide valuable insights into neurodegenerative diseases (e.g. - Multiple Sclerosis). In this work, we propose a multi-compartment model for T2-Relaxometry to obtain brain microstructure information in a quantitative framework. The proposed method allows simultaneous estimation of the model parameters.

4042

Computer 117 [Fast, Robust and Simultaneous \(FRoST\) relaxometry at polarizing field](#)Rashmi Rao¹, Shreyas Indurkar¹, Girish Koulagi¹, Nithin V Vajuvalli¹, Arush Honnedevasthana Arun¹, Sneha Potdar¹, and Sairam Geethanath¹¹Medical Imaging Research Centre, Dayananda Sagar Institutions, Bangalore, India

T_1 and T_2 measurements in polarizing field systems have long acquisition times due to the inclusion of a polarizer pulse. Current work demonstrates Fast, Robust and Simultaneous relaxometry (FRoST) measurements at Earth's field on water and CuSO_4 phantoms. FRoST creates a variation of the net magnetization through a series of CPMG acquisitions by varying the polarizing pulse (τ_p) to obtain simultaneous T_1 and T_2 weighting. T_1 and T_2 values obtained are similar to standard sequences and the acquisition time is reduced by 55%-84%.

4043

Computer 118 [Impact of Magnetic Susceptibility Anisotropy at 3 T and 7 T on \$T_2^*\$ -based Myelin Water Fraction Imaging](#)Eva Alonso Ortiz¹, Ives R. Levesque^{1,2}, and G. Bruce Pike³¹McGill University, Montreal, QC, Canada, ²Research Institute, McGill University Health Centre, Montreal, QC, Canada, ³University of Calgary, Calgary, AB, Canada

In this work we estimated the impact of myelin's magnetic susceptibility anisotropy on the Myelin Water Fraction (MWF) at 3T and 7T. We simulated realistic multicomponent T_2^* decay and then computed the MWF using three different fitting models. Our findings indicate that the effect of myelin's magnetic susceptibility anisotropy does not need to be considered when computing the MWF at 3T. However, failure to do so at 7T can lead to a significant bias in the MWF.

4044

Computer 119 [A Fast Multi-Contrast Knee Imaging Method Using a Hybrid bSSFP Pulse Sequence](#)Hyunseok Seo¹, Seohee So¹, Byungjai Kim¹, Yoonmee Lee¹, Kyungtak Min¹, and HyunWook Park¹¹Electrical Engineering, KAIST (Korea Advanced Institute of Science and Technology), Daejeon, Korea, Republic of

To increase the contrast between the bone and the cartilage, fat saturation techniques are additionally applied to the conventional imaging sequences. However, the fat saturation techniques eliminate most of the bone information. Thus, using the modified bSSFP (balanced steady-state free precession) pulse sequence called a hybrid bSSFP pulse sequence, the proposed method offers the multi-contrast knee images with very short imaging time (< 10 sec).

4045

Computer 120 [High Resolution Steady State Diffusion and Magnetization Transfer Imaging of the Spinal Cord](#)Matthias Weigel^{1,2} and Oliver Bieri^{1,2}¹Radiology, Radiological Physics, University Hospital Basel, Basel, Switzerland, ²Dept. of Biomedical Engineering, University of Basel, Basel, Switzerland

The potential of high resolution steady state diffusion and magnetization transfer (MT) imaging approaches with short acquisition times of less than 2min were investigated for the depiction of the spinal cord. As a surprising result, diffusion weighted time-reversed fast imaging with steady state precession (PSIF) sequences are not able to generate notable diffusion based contrast in the spinal cord (identical diffusion quotient $DQ = 1.96 \pm 0.20$). High resolution balanced steady state free precession (bSSFP) sequences, however, are able to depict MT induced signal saturation in spinal cord white matter (MT ratio = 0.30 ± 0.07).

Tuesday 13:45 - 14:45

4046

Computer 1 [Longitudinal Study of MS lesions using Multi-contrast Ultra-high Field \(7Tesla\) MRI](#)SANJEEV CHAWLA¹, Ilya Kister², Tim Sinnecker³, Jens Thomas Wuerfel⁴, Friedemann Paul⁵, and Yulin Ge⁶

¹Radiology, UNIVERSITY OF PENNSYLVANIA, Philadelphia, PA, United States, ²Neurology, Multiple Sclerosis Care Center, NYU School of Medicine, New York, NY, United States, ³Neurology, Universitätsspital, Basel, Switzerland, ⁴Medical Image Analysis Center, Basel, Switzerland, ⁵NeuroCure Clinical Research Center, Charité-Universitätsmedizin, Berlin, Germany, ⁶Radiology, NYU School of Medicine, New York, NY, United States

To track evolution of multiple sclerosis (MS) lesions, 9 patients underwent gradient-echo- T_2^* and quantitative susceptibility mapping on 7T MR system at baseline and at follow-up period (mean duration=2.4years). Majority of lesions were non-iron laden at baseline and most of them remained unchanged in size, morphology and susceptibility patterns. Some of these lesions accumulated iron deposition on follow-up. A minority of iron-laden lesions underwent redistribution of iron content. Small increase in lesion count was observed at follow-up. Interestingly, majority of these lesions were iron-enriched. This study may provide insights into pathophysiological features of MS lesions during the course of disease evolution.

4047

Computer 2 [A longitudinal study of neurite orientation dispersion and density imaging in relapsing-remitting multiple sclerosis](#)Elda Fisch-Gomez^{1,2,3}, Guillaume Bonnier^{1,2}, Pavel Falkowskiy^{3,4,5}, David Romascano³, Myriam Schlupe⁶, Renaud Du Pasquier⁶, Alessandro Daducci³, Jean-Philippe Thiran^{3,4}, Gunnar Kruger⁷, and Cristina Granziera^{1,2}

¹Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Department of Radiology, Charlestown, MA, United States, ²Harvard Medical School, Boston, MA, United States, ³Signal Processing Laboratory (LTS 5), Ecole Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland, ⁴Department of Radiology, Centre Hospitalier Universitaire Vaudois (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland, ⁵Advanced Clinical Imaging Technology (HC CMEA SUI DI BM PI), Siemens Healthcare AG, Lausanne, Switzerland, ⁶Department of Clinical Neurosciences. Neuroimmunology and Neurology, Centre Hospitalier Universitaire Vaudois (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland, ⁷Siemens Healthcare USA, Malvern, PA, United States

We explored the sensitivity of a novel diffusion MRI method i.e. "Neurite orientation dispersion and density imaging", to detect and characterize brain microstructure alterations in relapsing-remitting multiple sclerosis patients that we followed up over 2 years. Cross-sectionally, NODDI revealed that an increase in orientation dispersion and a decrease in neurite density in NAWM and in lesions of RRMS patients compared to healthy subjects. Longitudinally, NODDI measured a decreased dispersion and an increased neurite density in MS lesions at 2 years follow-up. Also, NODDI metrics at baseline were highly related to cognition at both baseline and follow-up.

Computer 3

Systematic Differences in High Angular Resolution Diffusion Imaging at Baseline in a Multicenter Longitudinal Clinical Trial
Ken Sakaie¹, Xiapeng Zhou¹, Josef Debbins², Mark Lowe¹, and Robert Fox¹

¹The Cleveland Clinic, Cleveland, OH, United States, ²Keller Center for Imaging Innovation, Barrow Neurological Institute, Phoenix, AZ, United States

The lack of imaging biomarkers is a key obstacle to the development of treatment for progressive multiple sclerosis. While diffusion MRI is a promising biomarker, variability among scanners may limit its use. We examine site-related variability among multiple sclerosis patients to inform the design of multicenter trials.

Myelin water imaging provides evidence of long-term remyelination and neuroprotection in Alemtuzumab treated multiple sclerosis patients
Irene Margaret Vavasour¹, Cornelia Laule^{1,2}, Shannon H Kolind^{1,3}, Roger Tam¹, David KB Li¹, Alex L MacKay^{1,4}, and Anthony L Traboulsee³

¹Radiology, University of British Columbia, Vancouver, BC, Canada, ²Pathology & Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada, ³Medicine (Neurology), University of British Columbia, Vancouver, BC, Canada, ⁴Physics and Astronomy, University of British Columbia, Vancouver, BC, Canada

To test the potential neuroprotective and reparative properties of alemtuzumab (a highly effective disease modifying therapy for relapsing remitting MS), we used myelin water imaging to measure myelination in MS patients treated with either alemtuzumab, interferon, or no treatment. NAWM MWF showed a steady 4% increase in alemtuzumab-treated subjects whereas MWF in subjects treated with interferon or without treatment decreased by 10% over 5 years. Myelin recovery following treatment with alemtuzumab supports previous clinical trial findings, provides understanding of the biological mechanisms underlying observed clinical improvement and demonstrates that MWF is a powerful biomarker for neuroprotection and repair in MS.

Myelin-Related MRI Metrics Demonstrate Longitudinal Differences for Relapsing MS Patients Treated with Ocrelizumab or Interferon Beta-1a Over 96 Weeks

Shannon Kolind^{1,2}, Irene Vavasour², Roger Tam², Lisa Tang³, Alexander Rauscher^{2,4}, Robert Carruthers¹, Rick White⁵, Victoria Levesque⁶, Hideki Garren⁶, David Clayton⁶, David Li², and Anthony Traboulsee¹

¹Neurology, University of British Columbia, Vancouver, BC, Canada, ²Radiology, University of British Columbia, Vancouver, BC, Canada, ³Biomedical Engineering, University of British Columbia, Vancouver, BC, Canada, ⁴Pediatrics, University of British Columbia, Vancouver, BC, Canada, ⁵Statistics, University of British Columbia, Vancouver, BC, Canada, ⁶Genentech, South San Francisco, CA, United States

Conventional MRI scans cannot evaluate disease-related changes in normal-appearing white matter, and have limited sensitivity for detecting changes in chronic lesions. In this work, we employed 2 quantitative MRI measures related to myelin content, myelin water fraction and magnetization transfer ratio, to evaluate the effects a potential novel therapy for multiple sclerosis (ocrelizumab) compared to a commonly-used therapy (interferon beta-1a). Over 2 years, these myelin-related measurements increased or remained stable in all regions for patients taking ocrelizumab, while they decreased for interferon beta-1a. These results support the use of quantitative MRI measures for more efficient, biologically specific clinical trial outcomes.

LONGITUDINAL ASSESSMENT OF LARGE-SCALE BRAIN FUNCTIONAL NETWORKS IN PATIENTS WITH MS: RELATIONSHIP WITH CLINICAL DISABILITY AND COGNITIVE IMPAIRMENT

Paola Valsasina¹, Maria Assunta Rocca¹, Fiammetta Pirro¹, Annalisa Colombi¹, Elisabetta Pagani¹, Ermelinda De Meo¹, Bruno Colombo², Paolo Preziosa¹, Vittorio Martinelli², Giancarlo Comi², Andrea Falini³, and Massimo Filippi¹

¹Neuroimaging Research Unit, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy, ²Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy, ³Department of Neuroradiology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy

Aim of this study was to investigate the temporal evolution of resting state (RS) functional connectivity (FC) in patients with multiple sclerosis (MS) and its correlation with clinical and cognitive worsening. The predictive value of baseline functional network measures on the worsening of clinical disability/cognitive impairment was also explored. No significant RS FC changes were detected in healthy controls, while MS patients showed a complex pattern of longitudinal changes in the different networks, with a trend towards an increase (or stability) of RS FC in clinically stable MS patients, and a decrease of RS FC in clinically worsened MS patients.

Aims of this large, multicenter study were to characterize baseline cervical cord atrophy in patients with multiple sclerosis (MS) compared with healthy controls, and to evaluate the modification of cervical cord cross-sectional area (CSA) over one-year of follow-up in such patients. Results indicated that baseline cord atrophy was present in MS patients vs controls, with a differential effect across phenotypes and a greater severity of atrophy in the progressive forms of the disease. Significant CSA decrease over time was found in relapsing remitting, primary progressive MS and in clinically worsened patients.

A longitudinal study of the effect of Multiple Sclerosis on surrounding white matter using z-spectrum imaging at 7T
Kingkam Aphiwatthanasumet¹, Olivier Mougini¹, Nick Geades¹, Nikos Evangelou², Richard Bowtell¹, and Penny Gowland¹

¹Physics and Astronomy, Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom, ²Neurology, Queen's Medical Centre, University of Nottingham, Nottingham, United Kingdom

MS lesions are known to evolve in time, many showing signs of remyelination. To investigate this, we considered the changes in the regions around existing lesions of varying ages, to test the hypothesis that there is ongoing tissue damage in the regions around white matter lesions in MS. We found that the quantitative MT measured at 7T values in the region surrounding MS lesions decreased over the period of a longitudinal 6 month study. No systematic trend was found for the lesion core. This supports the hypothesis that an MS lesion causes ongoing damage in the region surrounding the lesion.

Manifold valued statistical models for longitudinal analysis of MRI data

Nagesh Adluru¹, Hyunwoo J Kim², Richard J Davidson³, Andrew L Alexander⁴, Sterling C Johnson⁵, and Vikas Singh⁶

¹Waisman Center, University of Wisconsin-Madison, Madison, WI, United States, ²Computer Sciences, University of Wisconsin-Madison, ³Psychology and Psychiatry, University of Wisconsin-Madison, ⁴Medical Physics and Psychiatry, University of Wisconsin-Madison, ⁵Medicine, University of Wisconsin-Madison, ⁶Bioinformatics and Computer Sciences, University of Wisconsin-Madison

This work presents novel statistical image analysis methods to characterize complex morphological brain changes using MRI data. Specifically, our procedure utilizes the fundamental representations of "longitudinal change" -- voxel-wise Jacobian matrices obtained from image registration. Currently their univariate summaries (for example determinants) are ubiquitously used in neuroimaging studies. Operating directly with representations of Jacobians namely Cauchy deformation tensors, which are elements of an abstract mathematical manifold of symmetric positive definite matrices, yields promising improvements in statistical power in detecting subtle but statistically significant effects. The key technical contributions are computational algorithms for estimating multivariate general linear models with manifold-valued response variables.

A preliminary study: the Values of Quantitative Susceptibility Mapping (QSM) in CIS and MS in Children

Hua CHENG¹, Hong ZHANG¹, Yang FAN², TongLi HAN³, Yue LIU¹, and Yun PENG¹

¹Imaging Center, Beijing Children's Hospital, Capital Medical University, Beijing, People's Republic of China, ²MR Research China, GE Healthcare, ³Neurology Department, Beijing Children's Hospital, Capital Medical University, Beijing, People's Republic of China

Quantitative Susceptibility Mapping (QSM) has been well used in evaluating the iron quantity changes in adult patients with multiple sclerosis (MS). However, it has not been tested in pediatric MS patients. In the present study, QSM was applied to assess difference of iron quantity in clinically isolated syndrome (CIS) and MS in children. It is shown that QSM provides a superior sensitivity method in the detection iron of changes of MS-related tissue in children, which suggests that QSM may serve as a potential sensitive biomarker in pediatric MS.

In this study, diffusion tensor (DT) magnetic resonance imaging (MRI) was applied to describe brain structural network architecture and connectivity abnormalities underlying cognitive dysfunction in 53 pediatric multiple sclerosis (MS) patients in comparison to 26 age- and gender-matched healthy controls (HC). Global and local network analyses were performed to assess between-group differences of connectivity metrics and cortical hubs. Cognitive impairment in pediatric MS patients seemed to be mainly associated to a reduced strength of connections of structural hubs and loss of efficiency in information transmission.

4058

Computer 13

Longitudinal Changes in Magnetic Resonance Spectroscopy Over 96 Weeks in Relapsing MS Treated with Ocrelizumab versus Interferon Beta-1a

Erin L MacMillan¹, Julia J Schubert¹, Irene M Vavasour^{1,2}, Roger Tam², Alexander Rauscher², Rick White³, Hideki Garren⁴, David Clayton⁴, Victoria Levesque⁴, David KB Li², Anthony L Traboulsee¹, and Shannon H Kolind¹

¹Neurology, University of British Columbia, Vancouver, BC, Canada, ²Radiology, University of British Columbia, Vancouver, BC, Canada, ³Statistics, University of British Columbia, Vancouver, BC, Canada, ⁴Genetech, Roche Pharmaceuticals, South San Francisco, CA, United States

Single voxel magnetic resonance spectroscopy (MRS) was performed in thirty-seven relapsing multiple sclerosis (MS) patients, who were enrolled in a phase III clinical trial of ocrelizumab versus interferon beta-1a, at baseline, 24, 48, and 96 weeks follow-up. 24 healthy controls were also scanned. MRS demonstrated a significant interaction between visit and treatment group in the NAA/tCr ratio. The change in absolute metabolite concentrations over 96 weeks revealed that this interaction was primarily driven by increased NAA and reduced inflammation in the ocrelizumab group, while the interferon beta-1a group exhibited a smaller increase in NAA and ongoing inflammation.

¹Advanced Imaging Research Center, Oregon Health & Science University, Portland, OR, United States, ²Brigham & Women's Hospital, Harvard Medical School, ³Johns Hopkins, ⁴Yale, ⁵Siemens Medical Solutions, Portland, OR, ⁶University of California San Francisco, ⁷National Institute of Neurological Disease and Stroke, National Institute of Health, ⁸University of Toronto, ⁹Siemens Healthcare, Baltimore, MD, ¹⁰University of Southern California, Keck School of Medicine, ¹¹Oregon Health & Science University, Portland, OR, United States

The current lack of standardization in MRI protocols leads to increased variability, particularly in semi-quantitative techniques such as MTR, and makes comparisons between studies almost impossible. A single subject with clinically stable RRMS travelled to seven North American sites and underwent two distinct 3T MRI sessions following a standardized MTR and qT₁ protocol at each site. Both MTR and qT₁ mapping have been shown to have potential in elucidating tissue characteristics and underlying pathology. This work demonstrated that use of carefully standardized protocols produces consistent quantitative and semi-quantitative measurements across sites in MS brain tissue in-vivo.

Graph theoretical measures predict volumetric changes in multiple sclerosis

Thalis Charalambous¹, Carmen Tur¹, Ferran Prados^{1,2}, Steven H.P. van de Pavert¹, Declan T. Chard¹, David H. Miller¹, Sebastien Ourselin², Jonathan D. Clayden³, Claudia A.M. Gandini Wheeler-Kingshott^{1,4,5}, Alan J. Thompson¹, and Ahmed T. Toosy¹

¹UCL Institute of Neurology, Queen Square MS Centre, University College London, London, United Kingdom, ²Translational Imaging Group, Centre for Medical Image Computing, Department of Medical Physics and Biomedical Engineering, University College London, London, United Kingdom, ³UCL GOS Institute of Child Health, University College London, London, United Kingdom, ⁴Department of Brain and Behavioural Sciences, University of Pavia, Pavia, Italy, ⁵Brain MRI 3T Mondino Research Center, C. Mondino National Neurological Institute, Pavia, Italy

Numerous studies demonstrated structural network changes in patients with multiple sclerosis (MS). However, the predictive nature of the graph-derived metrics is not yet examined. In this longitudinal study, we constructed baseline diffusion-based structural networks and we used multiple linear regression analysis to assess the ability of the network measures to predict follow-up increased lesion load and brain atrophy in MS (n=49). Our results suggest that edge density, global and local efficiency can predict follow-up brain atrophy after adjusting for the nuisance variables, signifying that network analysis can provide new insights into disease trajectories and offer potential biomarkers for MS progression.

Lesion load and activity in multiple sclerosis (MS) patients, as identified by conventional magnetic resonance imaging (MRI), correlate only moderately with patients clinical status and evolution. Cortical lesion number and volume measured with advanced MRI may provide better correlates to cognitive dysfunction and disability. In this work, we studied the clinical impact of advanced MRI metrics of cortical and subcortical lesion evolution in a cohort of early relapsing-remitting MS patients. The number and volume of lesions that "shrunk", disappeared or remained stable over time were strong determinants of changes in cognition in our patients cohort.

Mondino National Neurological Institute, Pavia, Italy

Outer cortical magnetisation transfer ratio (cMTR) is potentially a sensitive measure of pathology linked to clinical disease progression in multiple sclerosis (MS). Here we aimed to investigate longitudinal outer and inner cMTR changes in healthy controls (HC) and people with MS of different clinical subtypes. Follow-up (FU) outer cMTR showed larger reductions in secondary progressive (SP)MS than other subtypes, and inner cMTR was also reduced more than in HC and relapsing-remitting (RR)MS, although cMTR was reduced in all MS patients at FU. This supports histopathological findings and suggests that cMTR measurement may be relevant to clinical disease progression in MS.

ACCURACY AND REPRODUCIBILITY OF AN AUTOMATED LESION SEGMENTATION TOOL-LESIONQUANT

Weidong Luo¹, Kelly Leyden¹, Aziz M Ulug^{1,2}, Sebastian Magda¹, Julia Albright¹, Robert Haxton¹, and Chris Airriss¹

¹CorTechs Labs, San Diego, CA, United States, ²Institute of Biomedical Engineering, Bogazici University, Istanbul, Turkey

Quantitative measures such as lesion volume and distribution have significant value for clinicians evaluating disease progression. Clinical standards for lesion evaluation include visual inspection of MRI images, or expert manual segmentation of lesions. These subjective measurements are often vulnerable to inter- and intra-rater variability, resulting in low reproducibility. CorTechs Labs' LesionQuant is a fully-automated lesion segmentation tool for clinical use designed to provide accurate and reproducible lesion segmentations. This study objectively evaluates the segmentation results of LesionQuant compared to expert manual segmentation.

Automated Lateral Ventricle Segmentation in Multiple Sclerosis – Assessing Reliability and Clinical Impact in a 5-Years Follow-Up Cohort Study

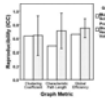

¹Medical Image Analysis Center AG, Basel, Switzerland, ²Department of Neurology, Universitätsspital Basel, Basel, Switzerland, ³Department of Neuroradiology, Universitätsspital Basel, Basel, Switzerland, ⁴Department of Neurology, University Hospital Düsseldorf, Düsseldorf, Germany, ⁵Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, University of Genoa and IRCCS S. Martino-IST, Genoa, Italy

As pars pro toto, lateral ventricle enlargement might give an indirect estimate of brain atrophy. In contrast to whole brain atrophy, ventricle enlargement is, however, clinically easy to assess and its quantification is robust to MR images of less than perfect quality. Here we investigate i) the applicability of an automatic lateral ventricle delineation algorithm (ALVIN) in multiple sclerosis (MS), and ii) the association between of lateral ventricle enlargement and clinical disability in MS longitudinally. We found that ALVIN reliably estimates the lateral ventricle volume in MS that is associated with whole brain atrophy and neurological as well as cognitive disability.

- 4068 Computer 21 [Using multi-inversion time ASL to explore gray matter perfusion in patients with multiple sclerosis: repeatability and relationship to disease characteristics](#)
 Ilona Lipp¹, Catherine Foster¹, Rachael Stickland¹, Alison Davidson¹, Richard G Wise¹, and Valentina Tomassini^{1,2}
¹CUBRIC, Cardiff University, Cardiff, United Kingdom, ²IRCCS Fondazione Santa Lucia, Rome, Italy

The first aim of this study was to investigate retest-reliability of gray matter perfusion estimates in patients with multiple sclerosis. Using multi-inversion time pulsed ASL, we demonstrate good repeatability of global and local perfusion estimates over a four-week interval. The perfusion estimates were consistently lower in the patients than in a group of healthy controls. The second aim was to relate GM perfusion to disease characteristics. We could not find an effect of disease duration or stage (relapsing-remitting vs progressive) on perfusion, but we did observe a weak correlation with cognition, supporting previous studies.

- 4068 Computer 22 [Reproducibility of Brain Network Metrics in People with Multiple Sclerosis](#)
 Thomas Welton¹, Dorothee P Auer¹, Cris S Constantinescu², and Rob A Dineen¹
¹Radiological Sciences, University of Nottingham, Nottingham, United Kingdom, ²Clinical Neurology, University of Nottingham, Nottingham, United Kingdom

Knowledge of reproducibility of graph-theoretic brain network metrics in disease populations is critically important for applications in clinical studies but non-existent in published literature. We compared reproducibility of graph metrics over time in a cohort of MS patients to reported values in published studies of reproducibility in healthy volunteers. We found that reproducibility was good in MS patients but slightly lower than in healthy people. Reproducibility of graph-theoretic brain network metrics in MS patients is not greatly dissimilar to that in healthy populations, which supports their use in clinical studies.

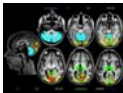

- 4068 Computer 23 [Progressive Iron Accumulation in Multiple Sclerosis Phenotypes Revealed by Sparse Classification of Deep Gray Matter](#)
 Ahmed M. Elkady¹, Dana Cobzas¹, Hongfu Sun¹, Gregg Blevins², and Alan H. Wilman¹
¹Biomedical Engineering, University of Alberta, Edmonton, AB, Canada, ²Division of Neurology, University of Alberta, Edmonton, AB, Canada

Purpose: To create an anatomically-interpretable framework for localized analysis of brain iron accumulation/demyelination, and apply this framework to Multiple Sclerosis (MS) Deep Gray Matter (DGM).

Materials and Methods: Quantitative Susceptibility and R2* maps were computed for 110 MS and 75 control subjects.

Results: Significant iron accumulation and insignificant demyelination were detected in MS DGM. Common MS pathological volumes and their pathological effect size progressively increased with advanced phenotypes. The developed framework offered improved statistical power and iron specificity compared to whole structure and singular analysis.

Conclusion: Using a novel localized analysis pipeline, we demonstrated the progressive iron accumulation in MS DGM.

¹Neurology, University of California, San Francisco, San Francisco, CA, United States, ²University of Pavia, Italy, ³DINOGLI, University of Genova, Italy, ⁴Imaging Genetics Center, Stevens Neuroimaging and Informatics Institute, University of Southern California, United States, ⁵Basel University Hospital, Switzerland

Fifty Multiple Sclerosis subjects were evaluated by optical coherence tomography and MRI, including multi-shell and putative myelin content imaging focused on primary visual area, thalamus and cerebellum. Predictive models of visual function performance, measured by visual evoked potentials and low contrast visual acuity were tested using a partial least square regression analysis. Combination of MRI and OCT metrics appears to strongly describe the visual function. Myelin content imaging, in particular, has a strong predictive value once there is history of optic neuritis. These preliminary results may improve the understanding of the pathological mechanisms underlying clinical dysfunction in multiple sclerosis.

Human and rodent imaging studies show that experience can lead to task-specific increases in brain structure, but the cellular and molecular basis of these changes is unknown. Here, we test the hypothesis that these volume changes depend on the same signaling pathways required for learning and memory formation. We exposed mice lacking CREB (a transcription factor critical for memory) to an enriched housing environment, and imaged their brains longitudinally over two weeks. Surprisingly, enrichment altered the neuroanatomy of all mice, regardless of CREB genotype. These findings provide evidence that the volume changes are due to CREB-independent processes.

MEMRI atlas-based assessment of brain volumes in adult NSG mice irradiated at birth

Balasarivasa R Sajja¹, Aditya N Bade², Mariano G Uberti¹, Michael D Boska^{1,2}, Howard E Gendelman², Santhi Gorantla², and Yutong Liu^{1,2}

¹Radiology, University of Nebraska Medical Center, Omaha, NE, United States, ²Pharmacology & Experimental Neuroscience, University of Nebraska Medical Center, Omaha, NE, United States

Use of HIV-1 humanized mice allows the evaluation of brain morphology affected by disease and disease altering therapies. We posit that such studies can elucidate the pathobiology of HIV-1 associated neurological disorders. As irradiation, administered at birth, is a required step for long-term graft integrity we evaluated the effect of irradiation on mouse brain development using manganese-enhanced MRI (MEMRI) atlas-based segmentation. Brain size reductions in irradiated mice showed substantive morphological alterations. Thus, evaluation of irradiation effects on brain morphology is a requisite step in assessments of virus-induced brain pathology.

¹Radiology, University of Maryland School of Medicine, Baltimore, MD, United States, ²Core for Translational Research in Imaging @Maryland, Baltimore, MD, United States, ³Pharmaceutical Sciences, University of Maryland School of Pharmacy, Baltimore, MD, United States, ⁴Harvard Medical School McLean Hospital, Belmont, MA, United States

A mouse model of late-stage alcoholic liver fibrosis (LALF) was used to investigate changes of neurochemical levels in specific brain regions that may relate to behavioral changes at LALF. Higher glutamine levels result in osmotic/oxidative stress were found in the thalamus and hippocampus of the alcohol-treated mice than in controls. Thalamic levels of taurine and creatine were significantly diminished and were strongly correlated with the alcohol-induced depressive behavior observed in an open field test. In addition, significant elevations in hippocampal glutamate were indicative of upregulated local glutamatergic activation. These pilot findings provide novel insight into the development of alcohol-induced HE.

The current study investigated the effect of sonic hedgehog agonist (SAG) treatment in post-stroke recovery. SAG- and vehicle-treated mice were evaluated with MRI at day 2 and day 30 after middle cerebral artery occlusion (MCAO) surgery. Our results show that SAG treatment showed significantly increased cerebral perfusion in the ischemic penumbra at day 30, suggesting enhanced angiogenesis. In addition, SAG-treated mice also exhibited decreased T2, suggesting reduced neuronal damage. These results suggest that the sonic hedgehog signaling pathway can be a potential therapeutic target for stroke treatment.

Myelin degeneration in cynomolgus macaques with advanced age using quantitative myelin imaging

Wenwen Yu¹, Zhe Wu², Hongjian He², Jianhui Zhong², and Zheng Wang¹

¹Institute of Neuroscience, Chinese Academy of Sciences, Shanghai, People's Republic of China, ²Center for Brain Imaging Science and Technology, Department of Biomedical Engineering, Zhejiang University, Hangzhou, People's Republic of China

Effects of normal aging on myelin have drawn considerable attention for decades. Previous studies hypothesized that myelin sheath degeneration could result in the reduction of the fraction of myelin water due to the inflow of intra- or extra-cellular water between myelin sheath. This study investigates aging effects on myelin degeneration in elderly macaques using a multi-echo GRE sequence. Using a three-pool model, we observed a significant decrease in the fraction of myelin water in the body of corpus callosum and a negative correlation with ages in 8 monkeys (aged 21~25), indicating heterogeneous degradation of white matter infrastructure with aging.

Effects of taurine on resting-state fMRI activity in rat model of attention deficit hyperactivity disorder

Hong-Chun Chou¹, Bor-Show Tzang², Vincent Chin-Hung Chen^{3,4}, and Jun-Cheng Weng^{1,5}

¹Department of Medical Imaging and Radiological Sciences, Chung Shan Medical University, Taichung, Taiwan, ²Institute of Biochemistry, Microbiology and Immunology, Chung Shan Medical University, Taichung, Taiwan, ³School of Medicine, Chang Gung University, Taoyuan, Taiwan, ⁴Department of Psychiatry, Chang Gung Memorial Hospital, Chiayi, Taiwan, ⁵Department of Medical Imaging, Chung Shan Medical University Hospital, Taichung, Taiwan

Attention deficit hyperactivity disorder (ADHD) is a most common developmental disorders in both children and adult population. However, the treatment for ADHD remains limited. To investigate the effects of taurine on ADHD, a spontaneously hypertensive rat (SHR) animal model was adopted in this study. The functional brain signals including functional connectivity (FC) and mean amplitude of low-frequency fluctuation (mALFF) were detected by using resting-state functional magnetic resonance imaging (rs-fMRI). Our findings in FC and mALFF suggested that taurine administration probably improves the hyperactive behavior in ADHD by changing brain functional signals in SHR rats.

Custom-built solenoid coils and 3D-printed rat brain slicers were used to identify and extract surgically placed inflammatory regions of interest within rat brains. The sequentially smaller and more sensitive coils combined with a highly-optimized gradient echo sequence, imaging setup, and registration algorithm achieved ultra high 25 μm isotropic resolution 3D MRI datasets. These images contained fully sampled k-space of the tissue pathology with preservation of the high frequency image details.

Social isolation in rats as a model for schizophrenia - a functional connectivity approach

Jonathan Rochus Reinwald¹, Robert Becker¹, Claudia Falfan-Melgoza¹, Anne Mallien², Dragos Inta², Peter Gass², Alexander Sartorius¹, and Wolfgang Weber-Fahr¹

¹Translational Imaging, Department of Neuroimaging, Central Institute of Mental Health, Medical Faculty Mannheim / Heidelberg University, Mannheim, Germany, ²Animal Models in Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim / Heidelberg University, Mannheim, Germany

Post-weaning social isolation rats are a widely used translational animal model for schizophrenia based on its typical schizophrenic-like behavioral alterations. Nevertheless, effects of isolation on functional brain connectivity are highly understudied. We used resting-state functional magnetic resonance imaging with seed-based and graph analyses to investigate effects of social isolation in rats on brain connectivity. Our major findings consistently demonstrated dysmodularity, hypofrontality, posterior hyperconnectivity and reorganization of the somatosensory cortex. These features resemble alterations of functional brain connectivity commonly observed in schizophrenic patients and other translational animal models, underlining the potential use of isolated rats as a translational model of schizophrenia.

- 4081 **Computer 60** **Characterizing the evolving property of de- and re-myelination in a mouse model using NODDI and MRI texture**

 Tim Luo¹, Peng Zhai¹, Olayinka Oladosu², Kahlil Rawji¹, and Yunyan Zhang¹
¹University of Calgary, Calgary, AB, Canada, ²Queens University, Kingston, ON
 Myelin injury and repair are associated with many neurological diseases including multiple sclerosis. We evaluated the utility of NODDI and MRI texture analysis for assessing myelin integrity using a mouse model of de- and re-myelination. Following lesion induction in mouse spinal cord, 9.4T MRI was conducted during demyelination (day 7) and ongoing remyelination (days 14, 28, and 35). With histological verification, both texture heterogeneity and neurite orientation dispersion (ODI) increased when demyelination occurs. But the latter showed persistent recovery with remyelination, similar to lesion size. These findings suggest the utility of ODI and texture heterogeneity as measures of myelin integrity.

¹Cube, Université de Strasbourg-CNRS, Strasbourg, France, ²Department of Radiology, Medical Physics, University Medical Center Freiburg, Freiburg, Germany, ³Laboratoire de Neurosciences Cognitives et Adaptatives, Université de Strasbourg-CNRS, Strasbourg, France, ⁴Centres Mémoire de Ressources et de Recherche, CHU de Strasbourg, Services Neurologiques et Gériatriques, Strasbourg, France, ⁵Département de Biophysique et Médecine Nucléaire, Hôpitaux Universitaires de Strasbourg, CHU de Haute-pierre, France
 Resting state functional magnetic resonance imaging (rsfMRI) has opened a new window into the brain and its connectome, proposing abnormal functional connectivity as a candidate biomarker of brain pathologies¹. We explored this pathway and performed rsfMRI and network analysis in the Thy-Tau22 transgenic mouse model of Alzheimer's disease, evaluating possible network signatures of early pathological states. We mapped the brain functional connectivity patterns and found overactive resting state BOLD signal in core players of the memory and learning systems, including the hippocampal network. This correlates with subtle memory deficits characterizing a very early pathological phenotype of the Thy-Tau22 mouse model.
-
- 4083 **Computer 62** **Imaging plasticity associated with hippocampal kindling using simultaneous LFP-ofMRI**

 Ben A Duffy¹, ManKin Choy¹, and Jin Hyung Lee²
¹Department of Neurology, Stanford University, Stanford, CA, United States, ²Departments of Neurology, Bioengineering, Neurosurgery, Electrical Engineering, Stanford University, Stanford, CA, United States
 The kindling model of epilepsy is associated with a permanent form of synaptic potentiation, which is considered to be pathological. In this study we used optogenetic fMRI to observe changes in plasticity that occur following a kindling regime. Upon stimulation of the ventral hippocampus, post-kindling fMRI data displayed significantly more widespread activation, particularly in pre-frontal regions compared to pre-kindling acquisitions. Simultaneous LFP measurements were used to confirm the absence of epileptic activity that would confound the interpretation. This represents a powerful technique which can be used for understanding cognitive impairments or understanding the mechanism of anti-epileptogenic therapies.
-
- 4084 **Computer 63** **MRI monitoring of the in vivo permeability increase of brain tumor vessels induced by synchrotron microbeam radiation therapy**

¹INSERM, Grenoble, France, ²University of Bern, Bern, Switzerland, ³INSERM, ⁴ESRF, ⁵University of Bern
 Synchrotron microbeam radiation therapy (MRT), a spatially fractionated preclinical radiotherapy, is more efficient than broad beam irradiation (BB) at opening the blood-brain tumor barrier of intracranial rodent glioblastomas. MRT-induced increase of tumor vascular permeability is significantly greater, earlier and more prolonged than in the BB alone group, especially in highly proliferative areas. MRT targeted all tumor regions, including areas not impacted by BB. High dose microbeams might be used to facilitate the delivery of intravenously injected drugs to tumoral tissue: Adjuvant chemotherapy might thus be more effective when coupled with MRT than with homogeneous radiation fields used in conventional radiotherapy.

¹Scripps Institution of Oceanography, University of California San Diego, San Diego, CA, United States, ²Radiology, University of California San Diego, San Diego, CA, United States, ³National Marine Mammal Foundation, San Diego
Summary
 Brain enlargement is associated with concomitant growth of interneuronal distance, increased conduction time, and reduced neuronal interconnectivity. Recognition of these functional constraints led to the hypothesis that large-brained mammals should exhibit greater structural and functional brain lateralization. As a taxon with the largest brains in the animal kingdom, Cetacea (whales, dolphins, and porpoises) provide a unique opportunity to examine asymmetries of brain structure and function. In the present study, diffusion tensor imaging (DTI) and tractography were used to investigate cerebral white matter asymmetry in the bottlenose dolphin.

Resting state functional MRI (rsfMRI) is currently the only non-invasive approach capable of giving insight into the large-scale cerebral networks architecture and its dynamic changes in pathology or following therapeutic interventions. With the aim of deciphering specific network signatures underlying memory and cognitive impairments in Down Syndrome pathology, we performed rsfMRI and network analysis in the Dp(16)1yey mouse model. We found perturbed synchrony of BOLD-signal in the hippocampal network of Dp(16)1yey mice. We further modulated this memory specific cerebral circuitry via therapeutic treatment with a DYRK1A kinase inhibitor, aimed at rescuing the memory and cognitive dysfunctions characterizing this mouse model.

¹CRUK and MRC Oxford Institute for Radiation Oncology, Department of Oncology, University of Oxford, Oxford, United Kingdom, ²Institute of Biomedical Engineering, Department of Engineering, University of Oxford, Oxford, United Kingdom

Arterial spin labelling (ASL) MRI is a useful clinical method of measuring blood flow in brain disorders such as tumours. This work presents a pre-clinical assessment of cerebral blood flow (CBF) by pseudo-continuous ASL in progressing rat breast cancer brain metastases. A statistically significant decrease in CBF of brain metastases was readily observed when tumours had grown sufficiently to breach the blood brain barrier, allowing gadolinium enhancement in T₁-weighted images. Upon histological analysis, the brain metastases proved to be hypoxic, consistent with a reduction in CBF in those regions.

¹Neuroscience curriculum, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, ²Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, ³Biomedical Research Imaging Center (BRIC), University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, ⁴Neurology, Chapel Hill, NC, United States, ⁵Radiology, Chapel Hill, NC, United States, ⁶Psychology, University of North Carolina at Chapel Hill, NC, United States, ⁷Neurology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, ⁸Biomedical Engineering, Chapel Hill, NC, United States, ⁹Cell Biology and Physiology, Chapel Hill, NC, United States

Several different neural systems are likely to be dysregulated to promote maladaptive behaviors associated with drug addiction. Here, we investigate changes in global functional connectivity across the brain following self-administration of cocaine and a period of abstinence in rats. We found whole brain enhancement in synchronized activity immediately following cocaine self-administration compared to pre-cocaine. Furthermore, whole brain network connectivity continued to strengthen following a period of abstinence. These data suggest that the dynamic shifts in functional connectivity following cocaine exposure persist during periods of abstinence and may provide a critical mechanistic link to relapse susceptibility.

In this paper, we proposed a set of fetal brain MRI analysis methods to quantify the fetal brain tissue volume. We used deep learning-based brain mask extraction method to obtain brain mask and reconstructed 3D fetal brain volumes using registration-based reconstruction method. Then an age-specific atlas-based segmentation method was applied to segment three major tissues (White Matter, cortical Gray Matter, cerebrospinal fluid). The changes of intracranial volume and the three brain tissue volumes across different gestational ages were calculated and fitted with both linear and quadratic curves. The results demonstrated the effectiveness of the automatic 3D fetal MRI quantification methods.

Developmental Susceptibility changes from neonate to early childhood using Quantitative Susceptibility Mapping (QSM)

Takuya Hinoda¹, Yasutaka Fushimi¹, Tomohisa Okada^{1,2}, Akira Yamamoto¹, Tsutomu Okada¹, and Kaori Togashi¹

¹Department of Diagnostic Imaging and Nuclear medicine, Graduate school of Medicine, Kyoto University, Kyoto, Japan, ²Human Brain Research Center, Graduate School of Medicine, Kyoto University

To assess the susceptibility changes in early childhood (0-45 months) and these consistencies with previous reports. In our study, 35 children were enrolled and QSM was calculated from 3D gradient-echo images. Susceptibility values in deep gray matter structures showed positive correlation with the subjects' age and theoretical iron contents, and these in white matter structures showed negative correlation in posterior peduncle of internal capsule and optic radiation. These results reflect the normal neural development in the early childhood and QSM can provide us quantitative methods to evaluate brain development.

4096

China, ³Department of Diagnostic Radiology, the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an 710061, P.R. China, People's Republic of China

Assessment of WM myelination is important to diagnose WM disorders in infants and children. We retrospectively evaluated 109 subjects (age of 6-48 months) using modified Cecilia Parazzini's scoring method based on T2WI visual evaluation. A significantly positive correlation was found between age and total scores of WM myelination with non-linear correlation coefficient of 0.948 ($p < 0.01$). TBSS results demonstrated WM myelination progressed rapidly during age of 6-20 months and relatively stable during age of 21-48 months. The modified scoring method was more applicable to assess the WM myelination in infant with age of 6-20 months.

Axon development revealed by directional diffusivities in intra-axonal and extra-axonal compartments

Xianjun Li^{1,2}, Miaomiao Wang¹, Heng Liu^{1,2}, Jie Gao¹, Xiaocheng Wei³, and Jian Yang¹¹Department of Radiology, the First Affiliated Hospital, Xi'an Jiaotong University, Xi'an, People's Republic of China, ²Department of Biomedical Engineering, the Key Laboratory of Biomedical Information Engineering of the Ministry of Education, School of Life Science and Technology, Xi'an Jiaotong University, Xi'an, People's Republic of China, ³MR Research China, GE Healthcare, Bei Jing, People's Republic of China

White matter in human brain undergoes a complex and long lasting process. It is not likely that conventional diffusion parameters are specific enough to distinguish axon-related and myelin-related processes. This study investigates directional diffusivities in intra-axonal and extra-axonal compartments on preterm neonates, term neonates, infants, and adults. Two change patterns of extra-axonal axial and radial diffusivities are found during development. This may be related to premyelination and myelination. Developmental changes of the fiber dispersion and intra-axonal diffusivities are observed in both pre-myelination and myelination periods. Directional diffusivities in intra-axonal and extra-axonal compartments provide more detailed information to evaluate axonal development.

4101

Computer 80

Characterization of Extensive Microstructural Variations Associated with Punctate White Matter Lesions in Preterm Neonates

Xianjun Li^{1,2}, Jie Gao¹, Miaomiao Wang¹, Edward S. Hui³, Xiaocheng Wei⁴, and Jian Yang¹¹Department of Radiology, the First Affiliated Hospital, Xi'an Jiaotong University, Xi'an, People's Republic of China, ²Department of Biomedical Engineering, the Key Laboratory of Biomedical Information Engineering of the Ministry of Education, School of Life Science and Technology, Xi'an Jiaotong University, Xi'an, People's Republic of China, ³Department of Diagnostic Radiology, the University of Hong Kong, Hong Kong, People's Republic of China, ⁴MR Research China, GE Healthcare, Bei Jing, People's Republic of China

Punctate white matter lesions (PWML) are common in preterm neonates. Neurodevelopmental outcome of the neonates is related to the lesion extensions. This study aimed to characterize the extent of microstructural variations for different PWML grades. White matter microstructural variations were different across PWML grades. The severe PWML were associated with extensive microstructural changes. Pattern of increased AD, increased RD, and reduced/unchanged FA was found proximal to the PWML. Unchanged AD, increased RD, and reduced/unchanged FA were observed in the vast regions distal from the PWML. These findings may help in determining outcomes of PWML and treatment strategies.

Computer 81

Convolutional Neural Networks for Identifying Preterm Infants at High Risk of Developmental Disorders

Ahmed Serag¹, Emma J Telford¹, Scott Semple¹, and James P Boardman¹

¹University of Edinburgh, Edinburgh, United Kingdom

Preterm birth is a major cause of neuropsychiatric impairment in childhood and leads to significant long-term clinical, educational and social problems. A major issue confronting clinicians who work with preterm infants and their families is the identification of infants who are most at risk for subsequent neurodevelopmental disability and who may benefit from early intervention services. We designed a system for the identification of preterm infants at high risk of developmental disorders using convolutional neural networks (CNN). The designed network yields an accuracy of 83.33%, and is applicable to the automated analysis of larger study cohorts.

4103

Computer 82

Music training enhances functional connectivity in preterm newborns

Serafeim Loukas^{1,2}, Lara Lordier^{1,3}, Frédéric Grouiller⁴, Didier Grandjean³, François Lazeyras⁵, Dimitri Van de Ville^{2,5}, and Petra S. Hüppi¹

¹Division of Development and Growth, Department of Pediatrics, University Hospital of Geneva, Geneva, Switzerland, ²Institute of Bioengineering, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ³Neuroscience of Emotion and Affective Dynamics Lab, Department of psychology, University of Geneva, Geneva, Switzerland, ⁴Swiss center for affective neurosciences, University of Geneva, Geneva, Switzerland, ⁵Department of Radiology and Medical Informatics, University of Geneva, Geneva, Switzerland

In this study we examined the impact of the environmental enrichment of preterm newborns with music on auditory cortex functional connectivity. A group of preterm infants listened to music from 33 weeks gestational age until term equivalent age. Two control groups were used: preterm and full-term infants without music. Auditory cortex functional connectivity with cerebral regions known to be implicated in tempo and familiarity processing were identified for preterm newborns that had music training during their stay in the NICU using Psychophysiological Interaction (PPI) analyses. Our results suggest that music training during hospitalization can modify functional connectivity in the newborn brain.

Early life predictors of brain development at term-equivalent age in infants born across the gestational ages.

Deanne K Thompson^{1,2,3}, Claire E Kelly¹, Jian Chen^{1,4}, Richard Beare^{1,4}, Marc L Seal^{1,3}, Peter J Anderson^{1,3}, Lex W Doyle^{1,5,6}, Alicia J Spittle^{1,5,7}, and Jeanie LY Cheong^{1,5,6}

¹Murdoch Childrens Research Institute, Melbourne, Australia, ²Florey Institute of Neuroscience and Mental Health, Melbourne, Australia, ³Department of Paediatrics, The University of Melbourne, Melbourne, Australia, ⁴Department of Medicine, Monash Medical Centre, Monash University, Melbourne, Australia, ⁵Royal Women's Hospital, Melbourne, Australia, ⁶Department of Obstetrics and Gynaecology, The University of Melbourne, Melbourne, Australia, ⁷Department of Physiotherapy, The University of Melbourne, Melbourne, Australia

Many early life factors contribute to how well a preterm child will develop, and these affect the brain differently based on how early the infant is born. The current study found that earlier gestational age is related to smaller brain volumes and less mature white matter at term-equivalent age. Correlated with these brain measures were lower birthweight SD score, multiple birth or high social risk. We show that infants born moderate and late preterm have altered brain development, not just those born very preterm, and there is a differential effect of early life predictors based on gestational age.

4105

The neonatal period is critical for brain development, however relationships between the brain and behaviour early in life are poorly understood. This study investigated relationships between whole brain, multimodal, quantitative magnetic resonance imaging (MRI) measures and neurobehavioural function in 257 preterm infants at term-equivalent age. Voxel-based morphometry and tract-based spatial statistics identified regions where grey and white matter volume and white matter microstructure were associated with various aspects of neurobehavioural function, with regions varying depending on the function. Thus, this study improves knowledge of brain-behaviour relationships early in life, which may help with predicting long-term outcomes and assessing early interventions to improve outcomes.

Neonatal whole brain volume and microstructure in infants born preterm and neurodevelopmental outcomes at 2 years of age

Claire E Kelly¹, Jeanie LY Cheong^{1,2,3}, Alicia J Spittle^{1,2,4}, Jian Chen^{1,5}, Marc L Seal^{1,6}, Peter J Anderson^{1,6}, Lex W Doyle^{1,2,3,6}, and Deanne K Thompson^{1,6,7}

¹Murdoch Childrens Research Institute, Melbourne, Australia, ²Newborn research, Royal Women's Hospital, Melbourne, Australia, ³Department of Obstetrics and Gynaecology, The University of Melbourne, Melbourne, Australia, ⁴Department of Physiotherapy, The University of Melbourne, Melbourne, Australia, ⁵Department of Medicine, Monash Medical Centre, Monash University, Melbourne, Australia, ⁶Department of Paediatrics, The University of Melbourne, Melbourne, Australia, ⁷Florey Institute of Neuroscience and Mental Health, Melbourne, Australia

Infants born preterm are at risk of neurodevelopmental delays in childhood, and MRI may improve knowledge of underlying cerebral changes. Relationships were investigated between whole brain volumes and microstructure in 256 preterm infants and neurodevelopmental outcomes at age 2 years using voxel-based morphometry and tract-based spatial statistics. Lower grey and white matter volumes and altered white matter microstructure were associated with poorer outcomes. In general, relatively widespread brain regions were associated with cognition, more central regions with cerebral palsy, and more peripheral regions with language. This study provides further understanding of how brain structure in preterm infants is related to longer-term outcomes.

¹Perinatal Imaging and Health, Kings College London, London, United Kingdom, ²Paediatric radiology, Great Ormond Street Hospital, London, United Kingdom, ³Biomedical engineering and imaging sciences, Kings College London, London, United Kingdom

The aim of this study was to ascertain the prevalence and type of incidental findings present in the low risk term brain using MRI. Out of 200 infants, 105 had incidental findings, with 8 requiring follow-up assessment. Common findings included subdural haemorrhage, punctate and cystic lesions and hyperintense signal of the basal ganglia. Findings requiring further assessment included subarachnoid, cerebellar, and germinal matrix haemorrhages, ectopic posterior pituitary lobe, subependymal heterotopia and venous infarcts. Prevalence of incidental findings in this cohort is significant. Communicating to parents the possibility of detecting abnormalities and referral pathways are important considerations in neonatal research.

Characterizing brain microstructural changes in childhood arterial ischemic stroke using multi-shell diffusion magnetic resonance imaging

Joseph Yuan-Mou Yang^{1,2,3}, Richard Beare^{3,4}, Belinda Stojanovski^{2,5}, Virginia J Maixner^{1,2}, Marc L Seal^{3,6}, and Mark T Mackay^{2,5}

¹Neurosurgery, Royal Children's Hospital, Melbourne, Australia, ²Neuroscience Research, Murdoch Childrens Research Institution, Melbourne, Australia, ³Developmental Imaging, Murdoch Childrens Research Institution, Melbourne, Australia, ⁴Stroke and aging research group, Department of Medicine, Monash University, Melbourne, Australia, ⁵Neurology, Royal Children's Hospital, Melbourne, Australia, ⁶Paediatrics, University of Melbourne, Melbourne, Australia

Imaging markers that can infer microstructural changes occurring in childhood arterial ischemic stroke (CAIS) may lead to a better understanding of the disease's neurobiological substrates. We applied both the Neurite Orientation Dispersion and Density Imaging (NODDI) and the Spherical Mean Technique (SMT) diffusion compartment models to two-shell diffusion data acquired in four acute CAIS patients. We demonstrate that parameter estimates derived from the stroke-affected regions were consistent with known microstructural changes described in acute stroke histopathology. The magnitudes of parameter changes were associated with stroke severity, and the motor outcomes at follow-up.

Amide proton transfer imaging of neonatal brain injury: a preliminary study

Yang Zheng¹, Xiaoming Wang², and Xuna Zhao³

¹Shengjing Hospital of China Medical University, shenyang, People's Republic of China, ²Shengjing Hospital of China Medical University, People's Republic of China, ³Philips Healthcare, People's Republic of China

The environment of the brain dynamically changes with neonatal brain development, and the topic of whether the application of magnetic resonance imaging (MRI) can reflect these brain environment changes is a recent one. In recent years, a new magnetic resonance contrast technology called amide proton transfer (APT) imaging has emerged which can detect protein and peptides through the signal from water (1), reflecting in vivo pH and protein concentration at the cellular and molecular level. The so-called amide proton mainly refers to the amide proton from the free protein and the polypeptide backbones.

Computer 89

Deep grey matter brain alkalosis in neonatal encephalopathy measured using 31P ISIS is associated with seizure burden and poor outcomes

David Price¹, Cristina Uria-Avellanal², Magdalena Sokolska¹, Subhabrata Mitra², Alan Bainbridge¹, Xavier Golay³, and Nicola Robertson⁴

¹Medical Physics and Biomedical Engineering, UCLH NHS Trust, London, United Kingdom, ²Neonatology, UCLH NHS Trust, London, United Kingdom, ³Institute of Neurology, University College London, ⁴Institute for Women's Health, University College London

31P image selected in vivo spectroscopy was used to measure deep grey matter intracellular pH in 43 neonates with hypoxic-ischaemic encephalopathy. All neonates had previously received therapeutic hypothermia, the current standard of care. Brain alkalosis was associated with poor outcomes reproducing what was found from whole-brain pH measurements in the pre-cooling era. Brain alkalosis was associated with increased seizure burden, the first time this has been shown in babies. Avoiding brain alkalosis could be a new objective for treating seizures and for neuroprotection in neonatal encephalopathy.

Diffusion-Weighted MR Signal Sparsity Indicates Impaired White Matter Organization in Lissencephaly

Vishal Patel¹ and Noriko Salamon¹

¹University of California, Los Angeles, Los Angeles, CA, United States

We demonstrate a novel technique for studying white matter pathology by examining the statistical properties of the DWI signal. We apply a sparse coding method, K-SVD, to decompose a diffusion-weighted series. We then quantify the efficiency of the resulting encoding by computing the Gini coefficient. We show that this measure is abnormally decreased in a cohort of lissencephaly patients compared to age-matched control subjects. Our results support the hypotheses that more organized white matter can be more sparsely encoded and that the sparsity of the encoding may thus be used to infer pathological white matter states.

4112

VOLUMETRIC BRAIN FINDINGS IN CHILDREN WITH SEIZURES

PhuaHwee TANG¹ and HsiaoPiau NG

¹*Diagnostic and Interventional Imaging, KK Women's and Children's Hospital, Singapore, Singapore*

Retrospective study of MRI brains with volumetric measurements done using voxel based morphology was conducted for children with seizures imaged in KK Women's and Children's Hospital since 2006. There was decreased cerebral volume and increased ventricular volume in children with hippocampal abnormalities compared to children with structurally normal brain, the difference in volumes exceeding 1 standard deviation, not statistically significant likely on account of the small sample sizes. Relative reduced grey matter to white matter is seen in children with hippocampal abnormalities as well as in children with neuronal migration abnormalities, reaching statistical significance in both groups.

4113

Imaging Genomics of Young Children with Global Developmental Delay: Preliminary DTI connectome study correlated with Allen brain atlas gene expression level

Jeong-Won Jeong^{1,2}, Harry Chugani³, Michael Behen^{1,2}, and Senthil Sundaram^{1,2}

¹*Pediatrics and Neurology, Wayne State University, Detroit, MI, United States*, ²*Translational Imaging Lab, Children's Hospital of Michigan, Detroit, MI, United States*, ³*Neurology, Nemours DuPont Hospital for Children, Wilmington, DE, United States*

This study is to investigate if different types of genetic mutations observed in children with global developmental delay (GD) are associated with white matter dysmorphologies and neuropsychological assessments. Eight children with GD having different mutations underwent a 3T MRI including diffusion tensor imaging with topological whole brain connectome analysis. Four of eight GD-associated mutations having high gene expression level in frontal and hippocampal regions showed apparently increased connectivity strengths in frontal and hippocampal regions which were significantly correlated with three behavioral phenotypes (IQ, memory, communication) suggesting that white matter abnormalities in different regions are perhaps driven by different genetic mutations.

CEREBELLAR TRACTOGRAPHY STUDY ON ADOLESCENT IDIOPATHIC SCOLIOSIS

Cindy Xue¹, Lin Shi², Steve C.N Hui¹, Tsz-ping Lam³, Bobby K.W Ng³, Jack C.Y Cheng³, and Winnie C.W Chu⁴

¹*Department of Imaging and Interventional Radiology, The Chinese University of Hong Kong, Hong Kong, Hong Kong*, ²*Department of Medicine and Therapeutics, The Chinese University of Hong Kong*, ³*Department of Orthopedics and Traumatology, The Chinese University of Hong Kong*, ⁴*Department of Imaging and Interventional Radiology, The Chinese University of Hong Kong*

Adolescent Idiopathic Scoliosis (AIS) is a 3-dimensional spinal deformity which occurs predominantly in adolescent girls. Impaired postural balance and tonsillar ectopia are reported findings in AIS. This study sought to investigate and compare white matter integrity of the cerebellar pathways in AIS with matched controls. Anatomically-guided deterministic tractography was used to reconstruct the cerebellar pathways. Lower FA value was found in spinocerebellar tract and in intracerebellar tract in AIS, suggestive of, reduced white matter integrity of the cerebellar pathway, which is in agreement with similar changes in other white matter pathways within the brain of AIS patients.

Increased Global Functional Connectivity in Hormonal Maturation Girls: a Resting-State Functional MRI Study

Wenjing Zhang¹, Yaxin Zhu², Di Yang², Peining Liu³, Zhihan Yan², and Su Lui¹

¹*Huaxi MR Research Center (HMRR), Department of Radiology, West China Hospital of Sichuan University, Chengdu, People's Republic of China*, ²*Radiology, The Second Affiliated Hospital & Yuying Children's Hospital of Wenzhou Medical University, Wenzhou, People's Republic of China*, ³*Child Health Care, The Second Affiliated Hospital & Yuying Children's Hospital of Wenzhou Medical University, Wenzhou, People's Republic of China*

To investigate the impact of hormone maturation on brain function and psychological development, seventy-three girls aged 6-11 years were enrolled. Using the global voxel-wise functional connectivity, we found that girls with hormonal maturation showed significantly greater functional connectivity strength mainly in the default mode network and limbic system, relative to girls who were not hormonally matured. While these two networks contribute substantially to the social cognition, cognitive processing and emotion regulation, our finding suggested that the hormonal maturation manifested its effects greatly on regions which are crucial to the social, self-referential, and emotional cognition development.

Longitudinal Hypergraph Learning: A Consistent Segmentation Method for Measuring the Growth Trajectory of Infant Hippocampus from Brain MR Images

Yanrong Guo^{1,2}, Pei Dong¹, Guorong Wu¹, Weili Lin¹, and Dinggang Shen¹

¹*Department of Radiology and BRIC, The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*, ²*School of Computer and Information, Hefei University of Technology, Hefei, People's Republic of China*

Automatic and consistent hippocampus segmentation from longitudinal infant brain MR image sequences is crucial for the measurement and analysis of its growth trajectory during early brain developing stage. To achieve this goal, we propose to use the longitudinal hypergraph method for joint learning the MR images from multiple acquisition time-points. We apply the proposed method to segment hippocampus from infant brain MR dataset which contains five time-points from 2 weeks to 12 months of age. According to the experimental results, our method outperforms other state-of-the-art label fusion methods in terms of both segmentation accuracy and consistency.

4117

Computer 96

Early Prediction of Cognitive Deficits in Very Preterm Infants using Machine Learning Algorithms

Lili He^{1,2} and Nehal A. Parikh^{1,2}

¹Perinatal Institute, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, ²Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati, OH, United States

By school age, 30-50% of very preterm infants exhibit cognitive deficits. Unfortunately, cognitive deficits cannot be reliably diagnosed until 3 to 5 years of age. These early years are now recognized as critical for neuroplasticity when early intervention therapies can enhance infants' ability to reach their full cognitive potential. Diffuse white matter abnormality (DWMA) is seen on term-equivalent age MRI in 50-75% of very preterm infants and is predictive of cognitive deficits. In this study, we examined features of DWMA and conducted personalized prediction in very preterm infants, soon after birth, using machine learning algorithms.

Detecting Perfusion Deficit in AD and MCI by Resting-State Functional MRI

Tianyuan Qian¹, Zhigang Qi², and Kuncheng Li²

¹MR Collaboration NE Asia, Siemens Healthcare, Beijing, People's Republic of China, ²Radiology, Xuanwu Hospital Capital Medical University, Beijing, People's Republic of China

Resting-state fMRI has been widely used to investigate the functional deficits of Alzheimer's disease (AD) and mild cognitive impairment (MCI). In this study, we applied this method to investigate the differences in tissue perfusion deficits between MCI, AD, and normal control (NC) groups. The results show that the AD and MCI groups have areas with less fast perfusion than normal controls. While the MCI group has more perfusion deficits in the frontal lobe, the AD group has more perfusion deficits in the parietal and occipital lobe.

4119

Computer 98

Degeneracy between apolipoprotein E $\epsilon 3$ and $\epsilon 4$ alleles predicts elderly episodic memory variation: a longitudinal study with independent validation

Hao Shu^{1,2}, Gang Chen², Zan Wang¹, Duan Liu¹, Guangyu Chen², B. Douglas Ward², Chunxian Yue¹, Fan Su¹, Lihua Gu¹, Feng Bai¹, Shi-Jiang Li², and Zhijun Zhang¹

¹Department of Neurology, Affiliated ZhongDa Hospital, Neuropsychiatric Institute and Medical School of Southeast University, Nanjing, People's Republic of China, ²Department of Biophysics, Medical College of Wisconsin, Milwaukee, WI, United States

We reported distinct EM neural correlates among APOE alleles in elderly subjects but still unclear whether and how the APOE $\epsilon 4$ carriers' distinct EM neural correlates contribute to an increased risk of AD onset. This study found that higher HFC strength in the EM neural correlates correlated with better longitudinal EM performance in the APOE $\epsilon 3\epsilon 3$ subjects but associated with inferior longitudinal EM performance in the $\epsilon 4$ carriers. These findings indicate that the degeneracy of EM function advance differential AD onset risk among APOE alleles, and provide a potential tool to predict APOE $\epsilon 4$ carriers with impending cognitive decline.

Reduced BOLD connectivity is related to hypoperfusion in Alzheimer's disease

Jens Goettler¹, Isabelle Riederer¹, Lorenzo Pasquini¹, Stephan Kaczmarz¹, Claus Zimmer¹, Christine Preibisch¹, and Christian Sorg¹

¹Department of Neuroradiology, Technische Universität München, Munich, Germany

BOLD-functional connectivity (BOLD-FC) is decreased in Alzheimer's disease (AD), and suggested to reflect reduced coherence of neural activity. However, the BOLD signal is based on vascular hemodynamics, therefore, impaired perfusion might also contribute to reduced BOLD-FC. Here, 32 AD patients and 22 controls underwent a simultaneous MR/PET, assessing BOLD-FC by resting-state fMRI, baseline CBF by pASL, and neuronal activity by FDG-uptake. Patients' BOLD-FC, CBF, and FDG-uptake were reduced within the same precuneal regions. BOLD-FC was positively associated with mean CBF, specifically in patients and independently from FDG-uptake. Data indicate that impaired vascular hemodynamics contribute to reduced BOLD-FC in AD.

Fibre-specific white matter changes in Alzheimer's disease: novel insights from Fixel-Based Analysis

Remika Mito^{1,2}, David Raffelt¹, Thijs Dhollander¹, David N Vaughan^{1,2,3}, Olivier Salvado⁴, Amy Brodtmann^{1,2,5}, Christopher Rowe^{6,7}, Victor L Villemagne^{2,6,7}, and Alan Connelly^{1,2}

¹Florey Institute of Neuroscience and Mental Health, Melbourne, Victoria, Australia, ²Florey Institute of Neuroscience and Mental Health, University of Melbourne, Melbourne, Victoria, Australia, ³Department of Neurology, Austin Health, Victoria, Australia, ⁴Health & Biosecurity, CSIRO, Brisbane, Queensland, Australia, ⁵Eastern Clinical Research Unit, Box Hill Hospital, Monash University, Victoria, Australia, ⁶Department of Medicine, Austin Health, University of Melbourne, Victoria, Australia, ⁷Department of Molecular Imaging & Therapy, Centre for PET, Austin Health, Heidelberg, Victoria, Australia

Alzheimer's disease (AD) is characterised by extensive white matter disruption, however voxel-based studies have been unable to provide fibre-specific insight into how this alters brain connectivity. Here, we applied fixel-based analysis (FBA) to diffusion MRI data to investigate changes in AD and mild cognitive impairment (MCI) patients. AD patients exhibited significant reductions in both fibre density and cross-section across multiple fibre tracts, while significant decreases in MCI were only evident in the posterior cingulum and uncinate, upon tract-of-interest analysis. This work demonstrates the value of FBA in identifying both macroscopic and microscopic changes to specific fibre pathways in the investigation of AD.

Computer 106

Can measuring hippocampal atrophy over a 3 year interval with a fully automatic method be substantially less noisy than manual?

Keith S Cover¹, Ronald A van Schijndel², Adriaan Versteeg², Alberto Redolfi³, Paolo Bosco³, Soheil Damangi⁴, Bob W van Dijk¹, Hugo Vrenken^{1,2}, Giovanni B Frisoni^{3,5}, and Frederik Barkhof²

¹Physics and Medical Technology, VU University Medical Center, Amsterdam, Netherlands, ²Radiology, VU University Medical Center, Amsterdam, Netherlands, ³IRCCS SanGiovanniDioFatebenefratelli, Italy, ⁴KarolinskaInstitutet, Stockholm, Sweden, ⁵University Hospitals and University of Geneva, Switzerland

The segmentation noise of hippocampal atrophy measurement methods can be measured using the back-to-back (BTB) reproducibility with the ADNI1 data set. Previous studies have only measured the segmentation noise over a one year interval. In the current study, two methods are shown to be substantially less noisy than manual hippocampal atrophy measurements over both 1 and 3 years - MAPS-HBSI and the recent FreeSurfer 6.0 Beta B (Build 20161008). Scatter plots of the 1 year versus 3 year BTB differences were found to be a particularly simple and effective way to display the segmentation noise of a method.

Loss of spatial navigation skills is a typical feature in mild cognitive impairment. Here we investigate intrinsic activity using resting-state functional magnetic resonance imaging within the subcortical regions, which is previously reported to be important in spatial navigation. Right hippocampus, pallidum and thalamus showed significant decreased regional homogeneity of local intrinsic activity in the patients, and the correlational trend between regional homogeneity and allocentric navigation performance showed significantly difference between patients and normal aging controls. These results showed evidences for the intrinsic subcortical activity damage and a possible compensatory mechanism of spatial navigation in the early mild cognitive impairment.

HYPOTHALAMIC-PITUITARY-GONADAL AXIS DYSREGULATION ALTERS RESTING STATE FUNCTIONAL CONNECTIVITY IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

FIRAT KARA¹, Michael Belloy¹, Garima Yadav¹, An Langbeen², Jules Jacobs³, Disha Shah¹, Steffen Roßner⁴, Peter Ponsaerts⁵, Marleen Verhoye¹, and Annemie Van Der Linden¹

¹Bioimaging Lab, Antwerp University, Antwerp, Belgium, ²Laboratory of Veterinary Physiology and Biochemistry, Antwerp University, Antwerp, Belgium, ³Mathematics, Leiden University, Netherlands, ⁴Paul Flechsig Institute for Brain Research, University of Leipzig, Leipzig, Germany, ⁵Experimental Cell Transplantation Group, Antwerp University, Antwerp, Belgium

Dysregulation of hypothalamic pituitary gonadal (HPG) axis signaling with menopause is considered as a risk factor for Alzheimer's disease (AD). Menopause leads to decreased sex steroid signaling and increased luteinizing hormone signaling which may have profound effects on many cellular processes that predispose to neurodegeneration and impairment in cognitive function. The effects of amyloid production on resting state BOLD fMRI using functional connectivity analysis in a mouse model of AD have been previously published. However how HPG axis dysregulation affect resting state functional connectivity in a mouse model of AD has not been studied. Here we show that ovariectomized AD mice, a commonly used animal model to study menopause related hormonal changes in the HPG axis, exhibit alterations in resting state connectivity in the mouse default mode network connectivity. These findings establish a causal link between AD and HPG axis dysregulation.

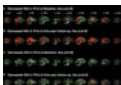

- 4131 **Computer 110** [Changes in susceptibility-weighted MRI contrast reflect differences in cortical spreading of pathology in early-onset and late-onset Alzheimer patients](#)

 Marjolein Bulk^{1,2}, Boyd Kenkhuus¹, Linda M. van der Graaf^{1,2}, Ingrid M. Hegeman³, Mark A. van Buchem¹, Remco Natté³, and Louise van der Weerd^{1,2}
¹Radiology, Leiden University Medical Center, Leiden, Netherlands, ²Human Genetics, Leiden University Medical Center, Leiden, Netherlands, ³Pathology, Leiden University Medical Center, Leiden, Netherlands
- Changes in susceptibility-based MRI contrast and histological correlates of post-mortem brain tissue have been used to distinguish differences in spreading patterns of AD pathology over the cortex between AD subtypes. Susceptibility-based MRI allowed us to clearly distinguish early-onset and late-onset AD patients. The MRI contrast in the different regions closely reflected the overall severity of pathology. This study confirms iron deposition as the underlying source of MRI contrast in all cortical regions, and demonstrates that iron deposition is a putative biomarker for disease progression, with a spatial and temporal spreading pattern independent of amyloid and tau.

¹Center for Basic and Translational Neuroscience, University of Copenhagen, Copenhagen, Denmark, ²Department of Anesthesiology, Yale University, New Haven, CT, United States, ³Cellular and Metabolic Research & NMR, University of Copenhagen, Copenhagen, Denmark, ⁴Department of Neurosurgery, University of Rochester, Rochester, NY, United States
- The link between hypertension and cerebral small vessel disease is key to understanding pathobiology of certain types of dementia. We studied the effects of mild hypertension on a newly discovered pathway for clearance of solutes from the brain parenchyma in young spontaneously hypertensive rats using DCE-MRI after intrathecal infusion of a paramagnetic contrast agent. We found normal-to-increased tracer influx and decreased efflux to and from the brain parenchyma, consistent with a lowered efficiency of brain solute clearance. This suggests that a compromised brain waste transport system may be implicated in the development of cerebral small vessel disease and dementia.

 Qing Wang¹, Yong Wang¹, Jon Christensen¹, Yi Su¹, Lisa Cash¹, John Morris¹, Mark Mintun², and Tammie Beninger¹
¹Washington University in St. Louis, St. Louis, MO, United States, ²Avid Radiopharmaceuticals, Inc., Philadelphia, PA, United States
- Accumulation of amyloid beta (A β) plaques and neurofibrillary tau tangles are the neuropathological hallmarks of Alzheimer disease (AD). However, increasing evidence points to the involvement of neuroinflammation in early AD and disease progression. Diffusion basis spectrum imaging (DBSI) is a novel non-invasive and non-radioactive multi-parametric diffusion MRI technique to quantify neuroinflammation in AD. We demonstrated that DBSI derived neuroinflammation marker significantly correlated with ¹¹C-PK11195 PET imaging, a marker for microglia activation and neuroinflammation, suggesting DBSI as a promising endogenous, non-radioactive method to quantify neuroinflammation in AD.

- Cerebral Blood Flow (CBF) as measured with ASL-MRI is an emerging Alzheimer's Disease (AD) biomarker. However, vascular pathology may delay the arterial transit time (ATT) of the magnetic label and influence the measurement. Thus, ATT estimation can potentially reveal vascular pathology and benefit CBF quantification. To evaluate CBF and ATT as read-out markers in AD mouse models, time-encoded ASL was used to measure ATT and CBF in the APP^{sw}/PS1 Δ E9 AD model. No major CBF difference was found when ATT was taken into account. However, AD mice showed increased ATT in the thalamus and decreased CBF in the cortex and striatum.

Young Onset Alzheimer's disease (YOAD) is characterised by its syndromic diversity, which may be underpinned by different patterns of white matter (WM) network breakdown. This prompts considerable interest in studying WM. We have previously shown that NODDI, a multi-shell diffusion MRI technique, is more sensitive at detecting WM changes in YOAD than standard DTI and demonstrated unique profiles of WM deficits in its syndromic variants. Here we investigated longitudinal WM changes in YOAD patients using NODDI, and explored the patterns of longitudinal WM changes associated with syndromic variants using tract-based spatial statistics (TBSS).

Automated Fiber Quantification Identifies the Extent of White Matter Integrity Loss Concurrent to Hippocampal Atrophy

Joseph A Helpert¹, George Russell Glenn¹, Andreana A Benitez², Fatima A Falangola³, Rachael A Deardorff¹, and Jens A Jensen¹

¹Radiology, Medical University of South Carolina, Charleston, SC, United States, ²Neurology, Medical University of South Carolina, Charleston, SC, United States, ³Neuroscience, Medical University of South Carolina, Charleston, SC, United States

Automated fiber quantification with white matter tract integrity metrics identified subtle changes in brain microstructure occurring in the early stages of Alzheimer's pathology. These metrics were found to be significantly different in the posterior section of the parahippocampal white matter in cognitively normal older adults with hippocampal atrophy as compared to those without. Axonal water fraction distinguished those with hippocampal atrophy versus those without with the largest effect size (Cohen's $d = 0.86$, $p = 0.004$). As expected, the metrics for these two groups did not differ in the arcuate fasciculus, a tract typically unaffected in Alzheimer's disease.

Oxidative stress has been implicated as an important pathological mechanism in the development of Alzheimer's disease (AD). The purpose of this study was to assess whether J-edited ¹H MRS levels of glutathione (GSH) – the primary antioxidant in living tissue – are associated with brain amyloidosis, as assessed with PET, and memory in a community-dwelling cohort of nondemented older adults. The results showed an inverse association relating GSH, a sensitive marker of oxidative stress, and amyloidosis, one of the pathological hallmarks of AD, and a weaker association with memory, thereby collectively further implicating oxidative stress in AD pathophysiology.

4139

The purpose of this study was to differentiate Alzheimer's disease (AD), dementia with Lewy bodies (DLB) and Parkinson's disease dementia (PDD) by evaluating deep gray matter regions of the three subject groups. The 3D T1 weighted images and quantitative susceptibility maps (QSM) were segmented into 15 deep gray matter structures to estimate volumes and mean susceptibility values, and differences among the three groups were evaluated using a one-way analysis of covariance (ANCOVA) with age and gender as covariates. A multivariate logistic regression and receiver operating characteristic curve analyses were performed to determine associated imaging features and diagnostic performance.

Quantitative susceptibility mapping (QSM) as a biomarker for evaluating white matter alterations in Parkinson's disease

Xiaojun Guan¹, Peiyu Huang¹, Qiaoling Zeng¹, Chunlei Liu², Min Xuan¹, Quanquan Gu¹, Xiaojun Xu¹, Nian Wang², Nian Wang², Xinfeng Yu¹, Xiao Luo¹, Jingjing Xu¹, Wei Luo³, Yong Zhang⁴, and Minming Zhang¹

¹Radiology, Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, People's Republic of China, ²Brain Imaging and Analysis Center, Duke University School of Medicine, Durham, NC, United States, ³Neurology, Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, People's Republic of China, ⁴MR Research, GE Healthcare, Shanghai, People's Republic of China

Myelinated white matter showing diamagnetic susceptibility is important for information transfer in the brain. In Parkinson's disease, the white matter is damaged secondary to nigral degeneration. Quantitative susceptibility mapping is a novel technique for noninvasive assessment of regional white matter ultrastructure, and provides different information to standard diffusion tensor imaging.

¹Department of Neurology, SNU-SMG Boramae Medical Center, Seoul, Korea, Republic of, ²Department of Radiology, SNU-SMG Boramae Medical Center, Seoul, Korea, Republic of, ³Department of Radiology, College of Medicine, Seoul National University, ⁴Department of Electrical and Computer Engineering, Seoul National University, Seoul, Korea, Republic of, ⁵Department of Mechanical and Aerospace Engineering, Seoul National University, Seoul, Korea, Republic of

This study is to evaluate the impact of quantitative susceptibility mapping (QSM) on regional distribution of iron deposition and its correlations with non-motor symptoms in patients with early Parkinson disease (PD). The QSM values of deep nuclei and clinical data using validated scales were obtained from patients. There were no differences in regional QSM values between patients and controls, and the QSM values were not correlated with any of motor or non-motor symptoms in PD patients. This study suggests that the QSM may not be a sensitive tool enough to use in patients with early PD.

Co-activation Pattern Analysis in Parkinson's Disease

Xiaowei Zhuang (co-first)¹, Ryan R Walsh (co-first)¹, Zhengshi Yang¹, Virendra Mishra¹, Karthik Sreenivasan¹, and Dietmar Cordes^{1,2}

¹Cleveland Clinic Lou Ruvo Center for Brain Health, Las Vegas, NV, United States, ²University of Colorado Boulder, Boulder, CO, United States

In this study, we explored the dynamics of Parkinson's disease (PD) brain network function utilizing the co-activation pattern (CAP) analysis emphasizing sensorimotor network (SM) function during resting-state. We modified the routine to calculate group dominant CAPs (d-CAPs) and proposed a novel way to obtain within-subject CAP switching-rate. Reduced dynamics of the SM network in PD was demonstrated by both decreased number of d-CAPs and decreased switching-rate, which corroborates electrophysiologic data.

Distinct structural backbone-network in early Parkinson's disease (PD) subjects: Insights from Parkinson's Progressive Markers Initiative (PPMI) dataset

Virendra Mishra¹, Karthik Sreenivasan¹, Christopher Bird¹, Dietmar Cordes¹, and Ryan R Walsh¹

¹Cleveland Clinic Lou Ruvo Center for Brain Health, Las Vegas, NV, United States

In vivo imaging that reliably captures the impact of the spreading pathology of Parkinson's disease (PD), including its impact on both white and gray matter, remains elusive. In this study, we applied graph-theoretical techniques to multi-site diffusion-MRI data from a cohort of early PD-subjects in Parkinson's Progressive Markers Initiative (PPMI) database. A distinctive structural backbone-network was revealed in early PD-subjects without any a-priori assumptions involving cortical and subcortical regions that are known to be involved in various stages of PD, including early PD (Olfactory-cortex, globus-pallidum, and striatum). Our study opens new avenues to understanding progression of PD from a graph-theoretical approach.

Computer 29

Characterizing diffusion MRI based structural connectome of the human brain in Parkinson's disease

Apurva Shah¹, Shivali Amit Wagle¹, Jitendra Saini², Pramod Pal³, and Madhura Ingahlalkar¹

¹Electronics and Telecommunication, Symbiosis Institute of Technology, pune, India, ²Department of Neurology, NIMHANS, Bangalore, ³Department of Neurology, NIMHANS, Bangalore, India

This study aims at assessing the large scale structural network changes in Parkinson's disease. The structural connectome is computed using probabilistic fiber tracking on diffusion MRI between 95 regions of interest. Graph theoretic analysis on the connectome is carried out at several levels of granularity: global, local (nodal) and lobar. We find that patients with PD demonstrate lower network clustering capability and lower neural connectivity as well as significantly reduced nodal influence of the hippocampus. Additionally, widespread patterns of reduced connectivity are observed in the temporal and occipital areas. These deficits could potentially mark the non-motor symptoms indicated in PD.

4147

Altered Topological Properties of Structural Connectome in Early-Stage, Drug-naive PD Revealed by Graph Theoretical Analysis
Xueling Suo¹, Du Lei², Nannan Li³, Lan Cheng³, Lei Li¹, Fuqin Chen⁴, Meiyun Wang⁵, Rong Peng³, and Qiyong Gong¹

¹Radiology, West china hospital, Chengdu, People's Republic of China, ²Psychosis Studies, Institute of Psychiatry, Psychology & Neuroscience, King's College London, United Kingdom, ³Neurology, West china hospital, People's Republic of China, ⁴Medical Information Engineering, School of Electrical Engineering and Information, Sichuan University, People's Republic of China, ⁵Radiology, Henan Provincial People's Hospital & the People's Hospital of Zhengzhou University, People's Republic of China

To use diffusion tensor imaging (DTI) and graph theory approaches to explore the brain structural connectome in patients with early-stage drug-naive Parkinson's disease (PD). The structural connectome was constructed by using deterministic tractography and thresholding the mean fractional anisotropy of 90 brain regions to yield 90*90 partial correlation matrixes. The decreased characteristic path length L_p and increased global efficiency E_{glob} in the PD patients relative to healthy controls indicated that structural networks are closer to randomization, providing a structural basis for functional alterations of PD.

Altered Dynamic Functional Connectivity State Patterns of Patients with Idiopathic Parkinson's Disease
Naying He^{1,2}, Shiyang Chen³, Jason Langley⁴, Yong Zhang⁵, Fuhua Yan¹, and Xiaoping Hu^{4,6}

¹Radiology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, People's Republic of China, ²Center for Advanced Neuroimaging, University of California, Riverside, Riverside, CA, United States, ³Department of Biomedical Engineering, Georgia Institute of Technology and Emory University, Atlanta, GA, United States, ⁴Center for Advanced Neuroimaging, University of California, Riverside, Riverside, CA, United States, ⁵MR Research, GE Healthcare, Shanghai, People's Republic of China, ⁶Department of Bioengineering, University of California, Riverside, Riverside, Riverside, CA, United States

Parkinson's disease (PD) is a neurodegenerative disorder characterized by nigral-striatal dopamine deficiency and motor symptoms. Neuroimaging studies have shown that functional connectivity within cortical-striatal networks and related connections are disturbed in PD. But these are based on conventional static resting-state analyses which assume functional connectivity being static over time. Recent studies have demonstrated that resting state brain activity is highly dynamic. In this work, we applied Gaussian Hidden Markov Model to investigate dynamic functional connectivity in PD and compared it with that in normal controls. Our results show alterations in sensorimotor, DMN, and visual networks in PD.

Parkinson's disease (PD) is characterized by the loss of pigmented dopaminergic neurons in the substantia nigra pars compacta (SNc). The aim of the study was to evaluate the feasibility of rapid magnetization pool size ratio (PSR) mapping as a subset of the magnetization transfer (MT) properties of the SNc in healthy subjects and patients with PD. These results demonstrated the feasibility of performing quantitative PSR mapping in human SN within reasonable scan times, and that PSR is likely the quantitative MT parameter most relevant for PD.

Computer 33

Abnormal Brain White Matter Connectivity in Diabetic Neuropathy: A Magnetic Resonance Diffusion Tensor Imaging Study.
Dinesh Selvarajah¹, Joseph Harding¹, Shillo Pallai¹, Solomon tesfaye², and Iain Wilkinson¹

¹University of Sheffield, Sheffield, United Kingdom, ²Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

This study for the first time has shown alterations in white matter MD in patients with DSPN. Increased MD in the primary somatosensory cortex in patients with diabetic neuropathy (DN) is suggestive of white matter microarchitecture degeneration, and supports the evidence of neuronal loss in the somatosensory cortex in patients with . Furthermore, these results also support the previous evidence of thalamic neuronal dysfunction in DN on MR spectroscopy. Changes in the degree of white matter structure might provide a pathophysiological underpinning of spinal cord atrophy and brain volume reduction in DN.

4151

Computer 34

Brain gray matter changes in type 2 diabetes mellitus: A meta-analysis of whole-brain voxel-based morphometry study
lin lin¹ and Guangyao wu¹

¹radiology, Affiliated Zhongshan Hospital of Dalian University, Dalian, People's Republic of China

To our knowledge, this is the first whole-brain VBM meta-analysis showing a reduced volume of whole and regional gray matter (GM) in the brains of type 2 diabetes mellitus (T2DM) patients. We used a new meta-analytic tool, signed differential mapping to identify consistent results about global and regional abnormalities in T2DM, and explore the relationship between cognitive and GM alterations. We showed reduced volume of whole and regional GM in T2DM patients, particularly in the temporal lobe, the GM volumes of the right insula were positively correlated with MMSE scores, and those changes may indicate a risk of dementia.

- 4152 Computer 35 **Altered White Matter Microstructure in Middle-Aged Type 2 Diabetic Patients: A Diffusional Kurtosis Imaging Study Based on Two-compartment White Matter Model**
Jie Gao¹, Min Tang¹, Xin Zhang¹, Xiaoling Zhang¹, Kaining Shi², and Xiaohong Wu¹
¹Shaanxi Provincial People's Hospital, Xi'an, People's Republic of China, ²Clinical science, Philips Healthcare China

This study aims to use a two-compartment diffusion model of white matter based on diffusional kurtosis imaging (DKI) to explore early white matter alterations in middle-aged type 2 diabetes mellitus (T2DM). 33 T2DM patients and 13 healthy control were enrolled. All diffusion parameters (FA=fractional anisotropy, MD=mean diffusivity, AD=axial diffusivity, RD=radial diffusivity, MK=mean kurtosis, AK=axial kurtosis, RK=radial kurtosis, D_a =intra-axonal diffusivity, $D_{e\parallel}$ =axial extra-axonal space diffusivity, $D_{e\perp}$ = radial extra-axonal space diffusivity) were compared. $D_{e\perp}$ was demonstrated to be the most sensitive in detecting the diffusion changes. These increased $D_{e\perp}$ (extra-axonal diffusivity) and unchanged D_a (intra-axonal diffusivity) reflected the increased water and/or demyelination.

- 4153 Computer 36 **An animal model of comorbid cerebral hypoperfusion and metabolic syndrome**
Jessica Livingston-Thomas¹, Greg O. Cron^{2,3,4}, Therese Gagnon⁵, Anthony Carter⁶, Matthew Jeffers⁵, and Dale Corbett^{5,6}
¹Cellular and Molecular Medicine, The University of Ottawa, Ottawa, ON, Canada, ²Medical Imaging, The Ottawa Hospital, Ottawa, ON, Canada, ³The Ottawa Hospital Research Institute, Ottawa, ON, Canada, ⁴Radiology, The University of Ottawa, Ottawa, ON, Canada, ⁵Cellular and Molecular Medicine, The University of Ottawa, ⁶Canadian Partnership for Stroke Recovery

Vascular cognitive impairment (VCI) arises from chronic cerebral hypoperfusion and is characterized by executive dysfunction, memory problems, and motor impairments. In countries where people eat highly processed, energy-dense food, there are high rates of VCI. Poor diet is also linked to metabolic syndrome, which is also associated with cognitive dysfunction. Metabolic syndrome and VCI commonly coexist within cardiovascular patients. Due to the translational failure of many promising preclinical treatments for cardiovascular disease, researchers are trying to incorporate human comorbidities within animal disease models. Here, we develop a rat model which combines cerebral hypoperfusion with an unhealthy diet.

- 4154 Computer 37 **MR-NODDI Evaluating Amyotrophic Lateral Sclerosis: a Tract Based Spatial Statistics Analysis**
Rifeng Jiang¹, Wenzhen Zhu², Qing Duan¹, Yunjing Xue¹, Yihao Yao², Jingjing Shi², and Linying Guo²
¹Fujian Medical University Union Hospital, Fuzhou, People's Republic of China, ²Tongji Hospital, HUST, Wuhan, People's Republic of China

This study uses NODDI, a novel tool, to quantify changes of white matter (WM) skeleton in patients with ALS. By TBSS analysis, significant FA reductions were demonstrated within the (pre)frontal WM, partial parietal WM, corpus callosum and partial corticospinal tract. Similarly, significant Fcivf reductions were found within almost all the WM skeleton, which was more extensive than that of FA. In contrast, ODI showed no significant changes in all the WM skeleton. Therefore, NODDI is a more potential tool to demonstrating the neurite density reductions for ALS patients, which will help lead to earlier diagnosis and treatment for ALS.

- 4155 Computer 38 **Reorganization of Brain Connectivity in the Speech and Language Network in the Non-fluent variant of PPA**

Graph theory analysis is a method recently introduced to study the brain as a network. In this study we investigate the topological distribution of the speech and language functional network in nfvPPA patients characterized by isolated and progressive language impairments. We identified the hubs of the speech and language network in healthy controls and nfvPPA. In patients, the network presented an abnormal topological distribution where right-sided brain regions were recruited. These findings suggest that in nfvPPA this network reorganizes in the presence of localized gray matter volume loss.

¹Institute of Radiology, University of Pavia, Pavia, Italy, ²Department of Neurology, University of California, San Francisco, San Francisco, CA, ³Memory and Aging Center, University of California, San Francisco, San Francisco, CA, ⁴Department of Radiology and Biomedical Imaging, University of California, San Francisco, San Francisco, CA, ⁵Department of Neuroradiology, IRCCS C. Mondino Neurological Institute, University of Pavia, Pavia, Italy, ⁶Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy

Diffusion restriction on MRI is an important diagnostic finding in sporadic Jakob-Creutzfeld disease. We performed group-wise quantitative cortical and subcortical grey matter mean diffusivity analysis at 3.0 T and tested feasibility of single-subject diffusivity restriction maps, that, compared to group-wise analysis, can better describe variable patterns of involvement in sJCD. DMN-related regions demonstrated prominent diffusion restriction; thus DMN functional connectivity was evaluated. DMN showed an increased connectivity in sJCD, that based on cross-sectional analysis seems to decrease along with clinical worsening. Resting-state fMRI may be a promising candidate to evaluate involvement in sJCD especially during the preclinical phase.

Structural and Functional MRI Characterization of Trial Spinal Cord Stimulation Responders in Failed Back Surgery Syndrome

Guangyu Chen¹, Andrew S. Nencka², Hao Shu^{1,3}, Shekar N. Kurpad⁴, Shi-Jiang Li¹, and Peter A. Pahapill⁴

¹Biophysics, Medical College of Wisconsin, Milwaukee, WI, United States, ²Radiology, Medical College of Wisconsin, Milwaukee, WI, United States, ³Neuropsychiatric Institute and Medical School, Southeast University, Nanjing, People's Republic of China, ⁴Neurosurgery, Medical College of Wisconsin, Milwaukee, WI, United States

Chronic pain is an important and growing problem in aging populations. A key challenge to treating chronic pain is the absence of effective, objective methods of assessment. This study, from a homogeneous group of chronic pain patients with failed back surgery syndrome, demonstrated that the functional interaction strength between the limbic striatum and neocortex were very tightly correlated with the patients' pain scores. We believe this index may form the basis for an objective, non-invasive biomarker for chronic lower back pain, and may be generalizable to other types of chronic pain.

Altered Structural Connectivity Networks in Young Adults Perinatally-infected with HIV

Mohammed Z Goryawala¹, Elizabeth J Willen^{2,3,4}, Anai M Cuadra², and Varan Govind¹

¹Radiology, University of Miami, Miami, FL, United States, ²Pediatrics, University of Miami, Miami, FL, ³Pediatrics, University of Missouri, Kansas City, MO, ⁴Developmental and Behavioral Sciences, Children's Mercy, Kansas City, MO

Milder forms of HIV-associated neurocognitive disorders (HAND) are frequently observed in approximately half of the HIV-infected individuals, even with treatment for HIV infection. Cognitive deficits observed in them can be associated with injury to the frontal and temporal lobes of their brains. The goal of this study was to assess the impact of HIV infection on vulnerable structural connections in these lobar regions in adults perinatally-infected with HIV. Our results indicate that altered connectivity in frontal lobe regions with differentiated modularity and significant alterations in hub patterns at the temporo-parietal junction occurred in the HIV group.

Neuroimaging studies suggest that white matter and cognitive function changes were affected by breast cancer and its treatments. Our study interested in the early effect of the brain by chemotherapy. This study included 19 breast cancer survivors who had completed their chemotherapy and 20 healthy control group. Generalized q-sampling imaging (GQI) with voxel-based analysis was performed to show the brain structural differences between two groups. Multiple regression was also used to detect the correlation between Mini-Mental State Examination (MMSE) and the indices of GQI. Our results provided further evidence that breast cancer and adjuvant chemotherapy are associated with adverse effects on white matter.

The association of MRI-detected brain volume change with prenatal exposure to Perfluoroalkyl Substances in teenage

Chao-Yu Shen^{1,2,3}, Shu-Li Wang⁴, Jeng-Dau Tasi⁵, Ju-Chien Wu², and Jun-Cheng Weng^{2,3}

¹Institute of Medicine, Chung Shan Medical University, Taichung, Taiwan, ²Department of Medical Imaging and Radiological Sciences, Chung Shan Medical University, Taichung, Taiwan, ³Department of Medical Imaging, Chung Shan Medical University Hospital, Taichung, Taiwan, ⁴National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan, ⁵School of Medicine and Department of Pediatrics, Chung Shan Medical University and Hospital, Taichung, Taiwan

The current study was to explore the relationship between prenatal exposure to PFASs, determined in maternal blood collected during the third trimester of pregnancy and the children's brain volume difference at the age of 13-15 years old. The results showed a significant negative correlation between the maternal blood PFASs concentrations and the children's brain MRI in multiple different brain areas, including both gray matter and white matter.

Diffusion magnetic resonance imaging for predicting changes in the severity of Progressive Supranuclear Palsy

Xiang-An Zhao¹, Lin Sung-Han¹, Tsai Chih-Chien¹, Wu Yi-Ming², Lin Wey-Yil³, Weng Yi-Hsin³, Lu Chin-Song³, and Wang Jiun-Jie¹

¹Medical Imaging and Radiological Sciences, Chang Gung University, Taoyuan City, Taiwan, ²Medical Imaging and Intervention, Chang Gung Memorial Hospital, Taoyuan City, Taiwan, ³Neurology, Chang Gung Memorial Hospital, Taoyuan City, Taiwan

Progressive Supranuclear Palsy (PSP) is an atypical Parkinsonism, which shared similar symptoms with Parkinson's disease (PD) and PSP progressed typically much faster than PD and the prognosis is often poor. The linear regression analysis demonstrated the capability of diffusion MRI indices as measured from multiple brain regions in the prediction of two-year clinical severity. Strong predictive power can be observed in mHY, motor subscale of UPDRS and PIGD. The two-year clinical decay in patients with PSP can be accurately predicted by using diffusion tensor derived parameters as measured from distinct brain regions.

An application of histogram analysis for multiparameters from multimodal MRI combining DCE, IVIM-DWI and 3D-Asl in predicating the Glioma grading and survival

Lin-Feng Yan¹, Xin Zhang¹, Yu Han¹, Yu-Chuan Hu¹, Hai-Yan Nan¹, Ying-Zhi Sun¹, Zhi-Cheng Liu¹, Yang Yang¹, Wen Wang¹, and Guang-Bin Cui¹

¹Tangdu Hospital, Xi'an, People's Republic of China

To find the early biomarkers for predicting the histological grading and prognosis of glioma, the study compared the discriminating efficiency of multiple metrics from DCE, Multi-b DWI and 3D-ASL with a histogram analysis approach, and further evaluated the combined accuracy and the survival association. The accuracy of assessing glioma grading and survival would not significantly improved by a univariate parameter, but highly promoted by combining the multiple parameters of histogram analysis from various MRI modality. We will further utilize the machine learning to evaluate the classifying accuracy.

ADC-Map Based Computer Aided Radiological Diagnostics (CARD) for the Initial Differential Diagnosis of Medulloblastoma versus Pilocytic Astrocytoma – A Reproducibility Study.

Urspeter Knecht¹, Nicole Porz², Beate Sick³, Elvis Murina⁴, Nuno Miguel Pedrosa de Barros⁵, Philippe Schucht⁶, Evelyn Herrmann⁷, Jan Gralla¹, Roland Wiest¹, Marwan El-Koussy⁸, and Johannes Slotboom⁹

¹Neuroradiology, University Hospital Bern, Bern, Switzerland, ²Neurosurgery, University Hospital Bern, Bern, Switzerland, ³Department of Biostatistics, Institute of Epidemiology, Biostatistics and Prevention, University of Zürich, Zürich, Switzerland, ⁴Institute for Data Analysis and Process Design, ZHAW, Switzerland, ⁵Neuroradiology, University Bern, University Hospital, Bern, Switzerland, ⁶Neurosurgery, University Hospital Bern, Bern, Switzerland, ⁷Radiooncology, University Bern, University Hospital, Bern, Switzerland, ⁸Neuroradiology, University Hospital Bern, Switzerland

The diagnosis of brain tumors using visual criteria is very challenging. A novel computational method for computer aided radiologic diagnostics (CARD) is described based on quantitative textural features from ADC-maps, and a machine learning algorithm (Random-Forest classification). The reproducibility of the method was examined with 3 human raters was performed, and the Fleiss's-Kappa-test revealed high inter-rater agreement of $\kappa=0.821$ (p -value $\ll 0.001$) and an intra-rater agreement of $\kappa=0.822$ (p -value $\ll 0.001$). The method significantly improves the differential diagnosis of medulloblastoma versus pilocytic-astrocytomas.

3D Parametric Histogram Analysis of Extravascular Extracellular Space for Identifying Subpopulations of Glioblastoma Related to Survival

Ka-Loh Li¹, Natale Quartuccio¹, Xiaoping Zhu¹, Samantha Mills, and Alan Jackson¹

¹Division of Informatics, Imaging and Data Sciences, The University of Manchester, Manchester, United Kingdom

Histogram Analysis of v_e was used for quantification of heterogeneity in glioblastomas and to study whether heterogeneity is related to survival. 27 patients with GBM were imaged. v_e histograms were processed by using a 4-mixture Gaussian distribution. Patients with short survival show an increasing proportion of the third Gaussian distribution. The mean of the 2nd Gaussian component, μ_2 , ($p = 0.00015$) and the weight of the 3rd components, w_3 ($p = 0.0066$) were the most predictive for survival. The identification of tissue components, characterized by Gaussian fitting of v_e values suggests that these represent, in some way, separate tissue subpopulations.

Evaluation of the Applicability of Territorial Arterial Spin Labelling in Meningiomas for Presurgical Assessments Compared with 3-Dimensional Time-of-Flight Magnetic Resonance Angiography

Yiping Lu¹, Bo Yin¹, Shihai Luan², Li Liu³, Ji Xiong¹, Jianbo Wen¹, Jianxun Qu⁴, and Daoying Geng¹

¹Department of Radiology, Huashan Hospital, Fudan University, Shanghai, People's Republic of China, ²Department of Neurosurgery, Huashan Hospital, Fudan University, Shanghai, People's Republic of China, ³Department of Radiology, Shanghai Cancer Center, Shanghai, People's Republic of China, ⁴MR Research China, GE Healthcare, Shanghai, People's Republic of China

In this research, territorial Arterial Spin Labelling (t-ASL) and unenhanced 3D-TOF-MRA were used to evaluate the usage in identification of the feeding vasculature of meningiomas in 20 consecutive patients. Results showed that the inter-observer agreement was excellent for the identification of the origin of the feeding arteries by t-ASL, which was better than the inter-observer agreement of 3D-TOF-MRA. The inter-modality agreement between t-ASL and 3D-TOF-MRA for the feeding arteries was moderate. The information about feeding arteries was potentially related to patients' symptoms and pathology, making it crucial for neurosurgeons in planning surgery and evaluating prognosis.

Three-dimensional pseudo-continuous arterial spin labeling(3D-pcASL) in differentiating tumor progression from treated effects in glioma

Yuelei Lyu^{1,2}, Bo Hou¹, Shuai Liu³, Hui You¹, Yu Wang³, Wenbin Ma³, and Feng Feng¹

¹Department of Radiology, Peking Union Medical College Hospital, Beijing, People's Republic of China, ²Department of Radiology, Beijing Chaoyang Hospital, Beijing, People's Republic of China, ³Department of Neurosurgery, Peking Union Medical College Hospital, Beijing, People's Republic of China

This study investigates the role of 3D-pcASL in discriminating between glioma progression (TP) and treatment related changes (TRC). We found that the maximum CBF (absolute value and its normalized values) in the lesion from 3D-pcASL were significantly higher in the TP group than in the TRC group. The ROC curve analysis showed the maximum CBF has an excellent performance in differentiating TP from TRC in patients with newly diagnosed glioma who have undertaken radiotherapy or chemoradiotherapy.

Proposed thresholds for parametric response mapping using intravoxel incoherent motion diffusion weighted imaging (IVIM-DWI) for the assessment of brain tumor treatment response

Ashley M Stokes¹, Jack T Skinner², Laura C Bell¹, Adrienne N Dula³, Thomas E Yankeelov³, and C. Chad Quarles¹

¹Translational Bioimaging Group, Barrow Neurological Institute, Phoenix, AZ, United States, ²Imaging Programs, National Comprehensive Cancer Network (NCCN), Philadelphia, PA, United States, ³University of Texas - Austin

The purpose of this study is to establish thresholds for parametric response mapping (PRM) using apparent diffusion coefficients (ADC) and intra-voxel incoherent motion (IVIM) parameters in healthy controls and to apply these thresholds in a cohort of brain tumor patients to study regional treatment-induced changes in diffusion and perfusion. We obtained thresholds (95% confidence intervals) of 0.38 and $0.32 \times 10^{-3} \text{ mm}^2/\text{s}$ for ADC and IVIM-D, respectively. For the perfusion-related distributions, the thresholds were $10 \text{ ml}/100\text{g}$ (IVIM- f_p) and $54 \text{ ml}/100\text{g}/\text{min}$ (IVIM- $f_p D^*$). This multi-parametric sensitivity to local tumor changes could be useful to simultaneously evaluate treatment-induced changes in perfusion and cellularity.

Repeatability of ktrans derived from DCE-MRI in newly diagnosed glioblastoma across multiple baseline images and processing methods. Andrew L Beers¹, Yi-Fen Yen², Kyrre Eeg Emblem³, Elizabeth R Gerstner⁴, Bruce Rosen², and Jayashree Kalpathy-Cramer²

¹Radiology, Massachusetts General Hospital, Boston, MA, United States, ²Radiology, Massachusetts General Hospital, ³Oslo University Hospital, ⁴Neurology, Massachusetts General Hospital

We evaluate the reproducibility of ktrans values derived from dynamic contrast MRI images in patients with newly diagnosed glioblastoma. Particular focus is put on the reproducibility across choices of T1 values and arterial input functions (AIFs) to the Tofts-Kermode model. Reproducibility is assessed across multiple pre-therapy baseline visits in a 45 patient cohort. Our model based on static population AIFs and static global T1 values had excellent reproducibility compared to other models including unique individual AIFs and T1 maps. There is relatively little concordance between all tested models, but individual AIFs led to higher mean ktrans values.

4173

Computer 8

Influence of Preload and Post-Processing Methods on the Consistency of Cerebral Blood Volume Values from Dynamic Susceptibility Contrast MRI

Laura C. Bell¹, Leland S. Hu², Ashley M. Stokes¹, Samuel C. McGee¹, Leslie C. Baxter¹, and C. Chad Quarles¹

¹Barrow Neurological Institute, Phoenix, AZ, United States, ²Mayo Clinic, Phoenix, AZ

With DSC-MRI, contrast agent leakage effects in high-grade gliomas must be resolved for accurate CBV measurements. Our aim is to compare CBV values across 1) varying preload doses, 2) two different previously published leakage correction methods, 3) normalized to either the AIF or normal appearing white matter (NAWM), and 4) different CBV integration limits. This was accomplished by acquiring six consecutive DSC-MRI with varying preloads in 14 glioma patients. We found that leakage corrected CBV measurements exhibit high consistency across variable preload doses, particularly when data is integrated under the "First Pass Only" and normalized to the AIF.

4174

Computer 9

True progression versus radiation necrosis in glioma: a comparative study of arterial spin labelling and dynamic susceptibility contrast imaging

Qian Xu¹, Kai Xu¹, Qi Liu¹, Hong Ma¹, Jiangfen Wu², and Jianxun Qu²

¹Department of radiology, Affiliation hospital of Xuzhou Medical University Department of Radiology, Xuzhou, People's Republic of China, ²GE Healthcare, Shanghai, People's Republic of China

Differentiation of treatment-related radiation necrosis from recurrent neoplasm is often difficult and dynamic susceptibility contrast perfusion MR imaging (DSC-MRI) is reported to be a surrogate marker for distinguishing them. However, DSC technique is invasive and has its disadvantage. Three dimensional pseudo-continuous ASL (3D-pcASL) can provide noninvasive absolute cerebral blood flow (CBF) measurement with insensitivity to permeability, and it is especially necessary for the evaluation of the postoperative gliomas patients where the blood-brain barrier (BBB) is completely broken with much more leakage effects. This study aimed to differentiate true progression from radiation necrosis of gliomas by using 3D-pcASL and DSC-MRI.

4175

Computer 10

Cerebral Blood Volume (CBV) Normalization for Dynamic Susceptibility Contrast (DSC) MRI in Glioblastoma Patients

Lei Qin¹, Xiang Li², Jinrong Qu², Katherine Leung³, Angie Li³, and Geoffrey S Young³

¹Dana-Farber Cancer Institute, Boston, MA, United States, ²Radiology, Affiliated Cancer Hospital of Zhengzhou University, ³Radiology, Brigham and Women's Hospital

Gaussian normalization generates more consistent nCBV maps than the gold standard, manual NAWM normalization. The ease of implementation and automated aspect of Gaussian normalization makes it an appealing method that could be successfully implemented in the clinical setting.

Preliminary Analysis of Neurite Orientation Dispersion and Density Imaging in Grading of Gliomas

Jing Zhao¹, Jian-ping Chu², Jing-yan Wang², and Xu Yan³

¹The First Affiliated Hospital of Sun Yat-sen University, Guang Zhou, People's Republic of China, ²The First Affiliated Hospital of Sun Yat-sen University, ³Shang Hai

Neurite orientation dispersion and density imaging (NODDI) was an advanced DWI. Our study is to quantitatively evaluate the diagnostic efficiency of NODDI in grading gliomas. 29 patients were recruited and they underwent whole-brain DWI which were collected at three b value (0, 1000 and 2000 s/mm²) and 1000 and 2000 s/mm² with 30 directions. Compared with LGG, ficvf and ODI are significantly higher in HGG and the mean value of ficvf showed the highest diagnostic value. Quantitative parameters from NODDI can aid in gliomas grading and the mean value of ficvf showed the highest diagnostic power.

4177

Computer 12

Diffusion kurtosis imaging: a novel tool to evaluate survival of glioma patients

Rifeng Jiang¹, Wenzhen Zhu², Lingyun Zhao², Qing Duan¹, Yunjing Xue¹, and Jingjing Jiang²

¹Fujian Medical University Union Hospital, Fuzhou, People's Republic of China, ²Tongji Hospital, HUST, Wuhan, People's Republic of China

DKI is a promising tool to predict the survival of glioma patients. MK, MD and ADC were significantly correlated with overall survival (OS) of patients with astrocytic tumor. By univariate Kaplan-Meier survival analyses, OS of the patients was related to tumor grade, Ki-67 LI, resection status, enhancement degree, edge, edema degree, lesion number, MK, MD and ADC (log rank $p < 0.05$ for all). Multivariate Cox regression analysis indicated that MK is an independent predictor of OS in these patients, and it is a risk factor ($P = 0.006$, $HR=2.142$ and 95% $CI=1.247-3.679$ for MK increasing every 0.1). These results are helpful to clinic.

4178

Predicting WHO grade of brain glioma using inflow-based vascular-space-occupancy MR imaging at 3 Tesla

Yuankui Wu¹, Shukun Liao¹, Danni Wang², Lichao Ma¹, Jun Hua^{3,4}, Yingjie Mei², Jun Wang⁵, Jun Zhou⁶, and Yikai Xu¹

¹Department of Medical Imaging, Nanfang Hospital, Southern Medical University, Guangzhou, People's Republic of China, ²School of Biomedical Engineering, Southern Medical University, Guangzhou, People's Republic of China, ³Neurosection, Division of MRI Research, Department of Radiology, Johns Hopkins University School of Medicine, Baltimore, Maryland, USA, ⁴F.M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, Maryland, United States, ⁵Department of Neurosurgery, Nanfang Hospital, Southern Medical University, Guangzhou, People's Republic of China, ⁶Department of Pathology, Nanfang Hospital, Southern Medical University, Guangzhou, People's Republic of China

The purpose of this study is to investigate the feasibility of grading primary brain gliomas with inflow-based vascular-space-occupancy (iVASO) MRI. The iVASO MRI perfusion approach enables the quantitative analysis of physiological information of tumor without using exogenous contrast agent. The measured arteriolar cerebral blood volume (CBVa) showed a significant association with tumor grades as well as the capability to predict tumors grades. When exogenous contrast agent administration is difficult or contraindicated in certain patient populations, iVASO MRI may be used as an option for the clinical management of brain tumors.

4179

Computer 14

Clinical Applications of Simultaneous Multi-slice (SMS) Imaging with High-angular-resolution Diffusion Imaging (HARDI) : a Comparative Study of Brain Tumor Pre-operative Evaluation with and without SMS

Louis-Olivier Bouchar^{1,2}, Christian Berthelot², and Maxime Villeneuve³

¹Radiology, Université Laval, Québec, QC, Canada, ²Radiology, CHU de Québec, Québec, QC, Canada, ³CHU de Québec, QC, Canada

Diffusion MRI can be helpful in pre-operative brain tumor evaluation to assess white matter tracts involved. It is however a time-consuming sequence, a problem that Simultaneous Multi-slice Imaging was designed to solve, although it has to demonstrate its quality non-inferiority. We compared in five patients tractographic data (using HARDI), acquired with and without SMS techniques, to evaluate the quality of imaging data as measured by the number of fibers between two regions of interest. We found that SMS-factor 2, cut time down by 37%, which is clinically relevant. We also found that SMS-2 is indeed non-inferior ($\alpha=0.03125$) and can be used without quality compromise.

Computer 15

Perfusion imaging of brain gliomas using arterial spin labeling: Correlation with histopathological vascular density in MRI-guided biopsies

Haopeng Pang¹, Ningning Di¹, Chengjun Yao², Yan Ren¹, Jingsong Wu³, Yong Zhang⁴, Jianxun Qu⁴, and Zhenwei Yao¹

¹Radiology, Huashan Hospital, Shanghai, People's Republic of China, ²Glioma Surgery Division, Huashan Hospital, Shanghai, People's Republic of China, ³Neurosurgery, Huashan Hospital, Shanghai, People's Republic of China, ⁴MR Research China, GE Healthcare, Shanghai, People's Republic of China

This study was designed to determine if CBF derived from ASL perfusion imaging could be used to quantitatively evaluate the MVD of brain gliomas on a "point-to-point" basis. The study enrolled 47 patients with treatment-naive brain gliomas who underwent preoperative ASL before stereotactic surgery. We histologically quantified MVD from CD34-stained sections of stereotactic biopsies and co-registered biopsy locations with localized CBF measurements. CBF showed a statistically significant positive correlation with MVD. ASL can be a quantitative and noninvasive perfusion MR method for evaluating the MVD of brain gliomas, and may reflect the microvasculature of gliomas.

4181

Computer 16

Non-invasive, contrast-exempt (NICE) assessment of glioblastoma (GBM) using multi-slice ASL and iVASO imaging

Jalal B. Andre¹, S Kristie McKown², and Swati Rane²

¹Radiology, University of Washington, Seattle, WA, United States, ²University of Washington

Assessment of cerebral and tumor perfusion has frequently been advocated for initial prognostication, and evaluation for possible progression, of primary brain tumors, historically accomplished via intravenous injection of a gadolinium-based contrast agent (GBCA). The potential for intracranial and corporeal deposition of GBCA invites the development and optimization of non-invasive, contrast-exempt (NICE) methods to assess cerebral perfusion. We sought to develop and implement NICE spin-label-based methods incorporating cerebral blood flow (CBF) and volume (CBV) assessment, applied in treated GBM patients.

4182

Computer 17

Intraoperative Arterial Spin Labeling – feasibility and first results

Thomas Lindner¹, Isabel Lübging², Christian von der Brelle^{2,3}, Michael Helle⁴, Olav Jansen¹, Michael Synowitz², and Stephan Ulmer^{1,5}

¹Clinic for Radiology and Neuroradiology, University Hospital Schleswig-Holstein, Kiel, Germany, ²Clinic for Neurosurgery, University Hospital Schleswig-Holstein, Kiel, Germany, ³Clinic for Neurosurgery, University Hospital Göttingen, Göttingen, Germany, ⁴Tomographic Imaging Department, Philips Research, Hamburg, Germany, ⁵Medizinisch Radiologisches Institut, Zurich, Switzerland

Performing MRI studies in an intraoperative setting is generally limited due to hardware and patient positioning restrictions. Structural imaging alone might not be sufficient to gather all required information. The goal of this study was to implement pseudo-continuous ASL in the intraoperative neurosurgical setting with limited hardware available and compare the images with measurements obtained pre-, and postoperatively on different clinical MRI scanners. The first application in a patient shows the potential of intraoperative ASL imaging with regards to visualizing residual tumor mass already during the surgical intervention in similar image quality.

4183

Computer 18

Evaluation of intravoxel incoherent motion in pituitary adenoma using turbo spin-echo diffusion-weighted imaging

Kiyohisa Kamimura¹, Masanori Nakajo¹, Yoshihiko Fukukura¹, Shingo Fujio², Takashi Iwanaga³, Tomoyuki Okuaki⁴, and Takashi Yoshiura¹

¹Radiology, Kagoshima University Medical and Dental Hospital, Kagoshima, Japan, ²Neurosurgery, Kagoshima University Medical and Dental Hospital, Kagoshima, Japan, ³Clinical Engineering Department Radiation Section, Kagoshima University Hospital, Kagoshima, Japan, ⁴Philips Healthcare, Tokyo

Our purpose was to evaluate the intravoxel incoherent motion (IVIM) in the pituitary adenoma using turbo spin-echo diffusion-weighted imaging (TSE-DWI). The f (perfusion fraction) in the pituitary adenoma was significantly lower than that in the normal pituitary gland, which is consistent with histopathologically known lower microvascular density in adenomas compared to normal pituitary tissue. There was no significant correlation between the f and the volume in pituitary adenomas. TSE-DWI-based IVIM imaging is a viable imaging technique for assessment of vascularity in skull base lesions including pituitary adenoma.

4184

Computer 19

Histogram Analysis of Intravoxel Incoherent Motion in Peritumoral Edema for Distinguishing between Central Nervous System Lymphoma and Other Brain Tumors

Kazuhiro Murayama¹, Takashi Fukuba², Shigeharu Ohyu³, Ayako Ninomiya³, Kazuhiro Katada⁴, and Hiroshi Toyama¹

¹Radiology, Fujita Health University, Toyoake, Japan, ²Radiology, Fujita Health University Hospital, Toyoake, Japan, ³Toshiba Medical Systems Corporation, Japan, ⁴Joint Research Laboratory of Advanced Medical Imaging, Fujita Health University, Toyoake, Japan

Additional benefits of quantitative analysis of peritumoral edema for distinguishing between brain tumors by diffusion weighted image or dynamic susceptibility contrast MRI has been described. Our aim was to investigate the hypothesis that quantitative analysis of intravoxel incoherent motion (IVIM) in peritumoral edema may be a useful parameter for distinguishing between central nervous system lymphoma (CNSL) and other brain tumors. Quantitative analysis of IVIM indicates that D^* and f maps of CNSL visually showed increase values in peritumoral edema. Our results indicate that these IVIM parameters have been successfully applied to obtain quantitative estimates of the vascularity and perfusion in peritumoral edema for differentiating CNSL and others without gadolinium contrast agent.

4185

Computer 20

Independent Component-based Denoising for Mapping Cerebrovascular Reactivity with Resting-State Fluctuation of BOLD Signal Amplitude in Patients with Gliomas

AI-LING HSU¹, Ping-Ni Wang², Jyh-Horng Chen³, and Ho-Ling Liu⁴

¹Imaging Physics, The University of Texas MD Anderson Cancer Center, Houston, TX, United States, ²Department of Medical Physics, University of Wisconsin-Madison, ³Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, ⁴Department of Imaging Physics, The University of Texas MD Anderson Cancer Center

Cerebrovascular reactivity (CVR) with hypercapnia challenges, such as a breath-hold (BH) task, has been proposed to indicate areas with neurovascular uncoupling potentials for presurgical fMRI. Previous studies have shown that BH response correlated with resting-state fluctuation of amplitude (RSFA) in healthy adults. This study explores the use of RSFA for indicating sites with neurovascular uncoupling potentials in presurgical fMRI of patients with gliomas. The RSFA with ICA-based denoising approaches was found to perform superior to the traditional approaches. Unlike BH, RS-fMRI is less dependent on patient performance thus can be widely applied in clinical practice.

4186

Computer 21

Active and passive fMRI for preoperative localization of motor function areas in brain tumor patients

Chen Niu¹, Xiao Ling¹, Pan Lin², Kun Zhang³, Xin Liu⁴, Liping Guo¹, Wenfei Li¹, Hao Song², Ming Zhang¹, and Maode Wang⁵

¹Department of Medical Imaging, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, People's Republic of China, ²Key Laboratory of Biomedical Information Engineering of Education Ministry, Institute of Biomedical Engineering, Xi'an Jiaotong University, ³Department of Electronics Engineering, Northwestern Polytechnical University, ⁴Technical University Munich, ⁵Department of neurosurgery, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, People's Republic of China

The aim of this study is to investigate whether there is consistency between active and passive movement in patients with brain tumors. Two motor tasks (active and passive hand movement) were applied to brain tumor patients. Our results demonstrate that there is no statistical difference of activation intensity between active hand movement and passive hand movement in patients with brain tumors. Our results suggest that passive movement fMRI provides a potential method for presurgical mapping in cases where patients are unable to comply with task instructions.

Brain Structural Network of Working Memory and Processing Speed for ALL Survivors

Junyu Guo¹, John O. Glass¹, JungWon Hyun¹, Yimei Li¹, Heather Conklin¹, Lisa Jacola¹, Ching-Hon Pui¹, Sima Jeha¹, and Wilbrun E. Reddick¹

¹St Jude Children's Research Hospital, Memphis, TN, United States

Acute lymphoblastic leukemia survivors may have significant deficits in processing speed and working memory even when treated with only chemotherapy. We investigate the relationship of diffusion tensor imaging metrics in an a priori brain structural network with neurocognitive functions such as processing speed and working memory. We found that fractional anisotropy values in the structural network were significantly positively associated with processing speed performance in two MR exams two years apart, and axial diffusivity values were negatively associated with working memory in the MR exam at the end of therapy. These findings may provide potential evidence for a structural neurocognitive network.

4189

Computer 24

Altered network topology in patients with primary brain tumors after fractionated radiotherapy

Naeim Bahrami¹, Tyler Seibert¹, Roshan Karunamuni¹, Jona Hattangadi-Gluth¹, Nikdokht Farid¹, Anders Dale¹, and Carrie McDonald¹

¹University of California, San Diego, San Diego, CA, United States

The purpose of this study is to determine whether brain structural network properties change in brain tumor patients following fractionated, partial brain radiotherapy(RT). We applied graph theory to MRI-derived cortical thickness estimates in 54 patients pre and post-RT and examine global and local changes in network topology. Increases in global efficiency, transitivity, and modularity were observed post-RT compared to pre-RT. Decreases in local efficiency and clustering coefficient were seen in regions receiving higher doses of RT. Our findings demonstrate alterations in global and local network topology following RT in patients with primary brain tumors.

Computer 30

[Expanding the Role of the Rapid Sequence MRI in Pediatric Neuroimaging](#)Cory Pfeifer¹, Amber Pokorney¹, and Patricia Cornejo¹¹*Phoenix Children's Hospital, Phoenix, AZ, United States*

The Image Gently campaign has resulted in increased awareness of radiation risks in the pediatric population. A major effect of this is a reduction in computed tomography in pediatric hospitals. While MRI may be able to achieve many of the goals of CT, risks related to sedation and the need for increased resources to perform sedated MRI must also be considered for children with conditions known to require follow-up imaging. In cases where children have external ventricular shunts in place over a long term, rapid sequence MRI has been well-described in its role to assess ventricular size while avoiding both ionizing radiation and sedation. Here we describe the use of our version of the rapid sequence MRI to assess additional indications, as more than half of the patients undergoing this study in our facility do not have indwelling ventricular shunt catheters at the time of imaging. Limitations of this technique are also discussed.

[Magnetic Resonance Imaging of Myelin Water: Principles and Applications](#)Cornelia Laule^{1,2,3}, Irene M. Vavasour¹, Shannon H. Kolind^{1,4}, Thorarin A. Bjarnason^{1,5,6}, Jing Zhang¹, Donna J.M. Lang¹, Hanwen Liu^{3,7}, Emil Ljungberg⁴, Roger Tam¹, Erin L. MacMillan⁴, John K. Kramer^{3,8}, Sandra Sirrs⁴, Piotr Kozlowski^{1,3,7}, Alexander Rauscher^{1,9}, Lara Boyd¹⁰, G.R. Wayne Moore^{2,3,4}, Anthony L. Traboulsee⁴, David K.B. Li^{1,4}, and Alexander L. MacKay^{1,7}¹*Radiology, University of British Columbia, Vancouver, BC, Canada, ²Pathology & Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada, ³International Collaboration on Repair Discoveries, University of British Columbia, Vancouver, BC, Canada, ⁴Medicine, University of British Columbia, Vancouver, BC, Canada, ⁵Interior Health, Kelowna, BC, Canada, ⁶Computer Science, Mathematics, Physics & Statistics, University of British Columbia Okanagan, Kelowna, BC, Canada, ⁷Physics & Astronomy, University of British Columbia, Vancouver, BC, Canada, ⁸Kinesiology, University of British Columbia, Vancouver, BC, Canada, ⁹Pediatrics, University of British Columbia, Vancouver, BC, Canada, ¹⁰Physical Therapy, University of British Columbia, Vancouver, BC, Canada*

Myelin water imaging (MWI) provides quantitative and specific mapping of myelin content in-vivo. Water trapped between myelin bilayers have a short T_2 relaxation time; the fractional proportion of this myelin water signal correlates strongly with histological staining for myelin. MWI has successfully been used to study both the brain and spinal cord where it can increase our understanding of development, aging and disease processes, and may also improve accuracy of diagnosis, prognosis and assessment of therapeutic response. Moving forward, MWI is expected to play an important role in the development and monitoring of new treatments targeted at remyelination and neuroprotection.

[The adaptive learning processing of establishing a research imaging core lab](#)Marina Salluzzi^{1,2}, Nicole Blenkin^{1,2}, and Richard Frayne^{2,3}¹*Calgary Image Processing and Analysis Centre, Foothills Medical Centre, Calgary, AB, Canada, ²Departments of Radiology and Clinical Neurosciences, Hotchkiss Brain Institute, University of Calgary, Calgary, AB, Canada, ³Seaman Family Research MR Centre, Foothills Medical Centre, Calgary, AB, Canada*

As institutions, agencies and governing bodies move toward increased value for invested research funds, core laboratory facilities have been found to be an effective solution to researcher needs. The Calgary Image Processing and Analysis Centre was envisioned as a core lab to support the local research community, and today it provides an evolving suite of services to facilitate the translation efforts in medical imaging research. CIPAC's evolution has been possible due to the synergy with local researchers striving for a quality solution to research image data management needs.

[Relation between brain temperature and cerebral perfusion and metabolism in human brain](#)Shunrou Fujiwara^{1,2}, Takaaki Beppu^{1,3}, Kuniaki Ogasawara¹, and Yoshichika Yoshioka^{2,4}

¹Department of Neurosurgery, Iwate Medical University, Morioka, Japan, ²WPI Immunology Frontier Research Center, Osaka University, Suita, Japan, ³Department of Hyperbaric Medicine, Iwate Medical University, Morioka, Japan, ⁴Center for Information and Neural Networks (CiNet), NICT and Osaka University, Suita, Japan

Brain temperature (BT) had traditionally been discussed whether it may be a simple parameter depending on body (core) temperature or it may regulate the neural activities; however, recent reports with magnetic resonance imaging (MRI) system demonstrated BT was strongly associated with the cerebral perfusion and metabolism in patients with ischemic change. Here, we reviewed BT measurement techniques with a MRI system and discussed the pathologic conditions causing BT alteration relating to the cerebral perfusion and metabolism.

Clinical Application of Synthetic MRI: Benefits and Pitfalls

Christina Andica¹, Akifumi Hagiwara^{1,2}, Misaki Nakazawa^{1,3}, Masaaki Hori¹, and Shigeki Aoki¹

¹Radiology, Juntendo University, Tokyo, Japan, ²Radiology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan, ³Radiological Sciences, Tokyo Metropolitan University Graduate School of Human Health Sciences, Tokyo, Japan

Synthetic MRI is a method of imaging based on the quantification of T1, T2, PD and B1 field by a single scan. The features of synthetic MRI such as; quantitative maps, tailored contrast-weighted imaging, brain tissue and myelin segmentation and volumetry show some advantages in the evaluation of brain disorders. However, some limitations were also noted.

Brain abscess due to odontogenic infection: Insights from dental CT for differential diagnosis.

Daiji Uchiyama¹, Katsumi Nakamura¹, and Takehisa Tsuji²

¹Radiology, Tobata Kyoritsu Hospital, Kitakyushu, Japan, ²Neurosurgery, Kitakyushu, Japan

We herein report the 4 cases of brain abscess secondary to odontogenic infection due to an untreated tooth decay. In all cases, there were no abnormalities on physical and intraoral examinations, nor overt trismus or facial swelling. Dental CT showed a periapical radiolucency around the root tips of a decayed tooth, which revealed periodontal abscess. After the multidisciplinary therapy including antibiotics, abscess drainage, and dental treatments, all the patients recovered and discharged.

The Review of Age-Related White Matter Changes in Alzheimer's Disease Trials

Dewen Yang¹

¹ICON Clinical Research, North Wales, PA, United States

Age-related white matter changes (ARWMC) are prevalent brain imaging findings and important substrates for cognitive impairment in the elderly. The true pathogenesis of ARWMC is not well understood. Previous studies verified that ARWMC also associate with cognitive decline. In Alzheimer's disease, ARWMC is also common findings on MRI images. The clinical importance of ARWMC in AD trials is reviewed.

Imaging features of myoepithelial carcinoma in the nasopharynx and paranasal sinus

Chunyan Zhang¹, Jingliang Cheng¹, Yong Zhang¹, Kangkang Xue¹, and Shaoyu Wang²

¹MRI Division, the First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, People's Republic of China, ²Siemens Healthcare Ltd., People's Republic of China

This study aimed to explore the diagnostic points of myoepithelial carcinoma (MEC) in the nasopharynx analyze through analysing the imaging features. 11 patients with MEC in the nasopharynx and paranasal sinus confirmed by pathology were analyzed retrospectively. CT and MRI appearances can localize the tumors, show tumors' size, and delineate the relationship of the lesions with the surrounding tissue. On CT findings, MEC easily has osteolytic destruction and on MR and ADC value it owns certain characteristic features. These characteristics are conducive to the early diagnosis and rational treatment in clinics.

Intraspinal bronchogenic cyst: Series of case reports and literature review

Xueying Ma¹, Dun Ding¹, Fengli Liang¹, Zhuonan Wang¹, Haining Li¹, Yingxiang Sun¹, and Ming Zhang¹

¹Imaging Medical, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, People's Republic of China

The purpose of this study was to provide a deeper knowledge of clinical presentation, imaging diagnosis, differential diagnosis and the management of the intraspinal bronchiogenic cysts. We retrospectively studied three cases of SBCs which were registered in our department and analyzed eight case reports which were all published in English. The SBCs can occur anywhere in the spinal canal, but they are more likely to present at the cervical canal and might be along with some developmental malformations of spine. We emphasize the role of MRI findings in the diagnosis before surgery. It is recommended that the lesion should be removed as completely as possible on the premise of protecting the spinal cord from being injured.

The study of brain iron by SWI and T2* imaging in Parkinson's disease

Lixia Yang¹ and Yu Cheng¹

¹Department of image center, Shanghai Xuhui central hospital, Shanghai, Shanghai, People's Republic of China

Both Susceptibility Weighted Imaging (SWI) and T2 star (T2*) imaging can measure the brain iron deposition. However, the two ways by which the brain iron is measured are not compared. This study measured the brain iron of healthy volunteers and Parkinson's disease patients by SWI and T2* imaging. we found that SWI and T2* imaging could estimate the brain iron, and the SWI radiant values of SNr and RN were significance difference between healthy volunteers and Parkinson's disease patients, suggesting the SWI had better reliability to diagnose the Parkinson's disease than the T2* imaging.

Neuroimaging plays critical diagnostic and prognostic role in the management of brain tumors. However, there can be a significant overlap in the imaging features between neoplastic and various non-neoplastic pathological processes in the brain. The knowledge of key differentiating features of such non-neoplastic entities is essential for a radiologist to facilitate accurate and timely diagnosis. Additionally, in such settings, judicious use of advanced imaging techniques such as perfusion imaging and spectroscopy can help the radiologist as problem-solving tools. In this exhibit, we review the conventional and advanced imaging features of different disease processes that are encountered in day-to-day clinical practice and can mimic brain neoplasms on imaging.

4207

Computer 42

Image Quality Comparison of High Resolution PC-MRA (4D-Flow) with Time of Flight in Healthy Volunteers

Warren Chang¹, Michael Loecher¹, Daniel B Ennis¹, Aichi Chien¹, and J. Pablo Villablanca¹

¹Department of Radiological Sciences, University of California, Los Angeles, CA, United States

In this study, image quality of high resolution PC-MRA (4D Flow) and 3D-TOF was compared. Ten healthy volunteers were scanned with high resolution 4D-Flow and 3D-TOF angiograms at 0.5 mm isotropic spatial resolution in clinically-useful scan times of 7 and 12 minutes. There was no significant difference in image quality between 4D Flow and 3D-TOF in both source images and MIPs. 4D Flow acquisitions were velocity encoded, allowing hemodynamic evaluation of intracranial structures. This study demonstrated that phase-contrast techniques such as 4D-Flow have comparable image quality to 3D-TOF while obtaining velocity measurements, showing promise as a viable alternative to 3D-TOF.

Elevated Glycine and Glutamate Metabolite Levels in Patients with First-Episode Psychotic Disorders Measured by TE-averaged PRESS at 4 T

Sang-Young Kim^{1,2}, Marc J. Kaufman^{1,3}, Bruce M. Cohen⁴, Joseph T. Coyle⁵, Fei Du^{1,2}, and Dost Ongür²

¹McLean Imaging Center, McLean Hospital, Harvard Medical School, Belmont, MA, United States, ²Psychotic Disorders Division, McLean Hospital, Harvard Medical School, Belmont, MA, United States, ³Translational Imaging Laboratory, McLean Hospital, Harvard Medical School, Belmont, MA, United States, ⁴Program for Neuropsychiatric Research, McLean Hospital, Harvard Medical School, Belmont, MA, United States, ⁵Laboratory for Psychiatric and Molecular Neuroscience, McLean Hospital, Harvard Medical School, Belmont, MA, United States

In this work, we present the advantage of TE-averaged PRESS approach to reliably quantify brain glutamate and glycine levels in vivo in patients with psychosis. Since glutamatergic dysregulation and NMDA receptor hypofunction are implicated in the pathophysiology of major psychiatric conditions, non-invasive in vivo assessments of glutamate and its NMDA receptor modulator, glycine, would be of great importance. We found significantly elevated glutamate and glycine levels in the anterior cingulate cortex and parieto-occipital cortex of patients with first-episode psychosis as compared to healthy controls, suggesting increased brain glutamatergic activity with compensatory attempts to correct for NMDA receptor hypofunction.

Modular organization of functional connectivity in schizophrenia patients beyond the resolution limit

Cecile Bordier¹, Carlo Nicolini¹, and Angelo Bifone¹

¹Center for Neuroscience and Cognitive Systems, Istituto Italiano di Tecnologia, Rovereto (TN), Italy

Graph theoretical methods have been widely applied to study the modular organization of functional connectivity networks in neuropsychiatric disorders like Schizophrenia. However, current methods are affected by a resolution limit that prevents detection of modules that are smaller than a scale determined by the size of the entire network. We have developed a resolution-limit-free method, dubbed Surprise, and applied it to study resting state functional connectivity networks in a large cohort of Schizophrenia patients and matched controls. Improved resolution reveals substantial reorganization of resting state connectivity structure in patients, with previously undetected fragmentation and merging of sensory and associative modules.

Computer 52

Decreased Brain Nicotinamide Adenine Dinucleotide (NAD) Levels in Adolescent Bipolar Disorder

Young-Hoon Sung^{1,2}, Xian-Feng Shi^{1,2}, Perry F. Renshaw^{1,2,3}, and Douglas G. Kondo^{1,2,3}

¹Brain Institute, Salt Lake City, UT, United States, ²University of Utah Department of Psychiatry, Salt Lake City, UT, United States, ³Veterans Administration Rocky Mountain MIRECC for Suicide Prevention, Salt Lake City, UT, United States

Converging evidence implicates mitochondrial dysfunction in bipolar disorder (BPD). Treatments of adolescent BPD have limited efficacy, and are associated with significant toxicity. Phosphorus magnetic spectroscopy imaging (³¹P MRSI) may shed light on the pathophysiology and neural markers of adolescent BPD. In the present study, nicotinamide adenine dinucleotide (NAD) levels were measured using ³¹P MRSI in 15 adolescents with BPD and 23 healthy controls (HC). BPD adolescents had significantly decreased NAD levels compared to HC. Clinical trials of NAD precursors are required to determine whether restoration of NAD levels is feasible, and can serve as a treatment for adolescent BPD.

Computer 53

White matter structure asymmetry of drug-naïve first-episode schizophrenia patients under different genetic load

Wenbin Li¹, Huaiqiang Sun¹, Su Lui¹, and Qiyong Gong¹

¹West China Hospital, Chengdu, People's Republic of China

We analyzed the white matter (WM) asymmetry in a relatively large sample of drug-naïve schizophrenia patients under different genetic load. Based on this method, our findings demonstrated similar overall WM brain torque in sporadic and familial schizophrenia patients and healthy controls. Furthermore, our observation that familial illness was associated with more abnormal brain asymmetry compared to sporadic patients and that these specific changes were mainly located in a functional network associated with auditory hallucinations suggesting genetic factors may play critical roles in impacting risk for the most common form of hallucinations in schizophrenia.

Computer 54

Connectome-wide exploration of altered resting-state connectivity in combat veterans with and without PTSD and real-time fMRI neurofeedback training effect on abnormal connectivity

Masaya Misaki¹, Raquel Phillips¹, Vadim Zotev¹, Chung Ki Wong¹, Frank Krueger², Matthew Feldner³, and Jerzy Bodurka^{1,4}

¹Laureate Institute for Brain Research, Tulsa, OK, United States, ²Department of Psychology, George Mason University, Fairfax, VA, United States, ³Department of Psychological Science, University of Arkansas, Fayetteville, AR, United States, ⁴College of Engineering, Stephenson School of Biomedical Engineering, University of Oklahoma, Tulsa, OK, United States

In combat veterans with and without PTSD diagnosis, we performed connectome-wide exploration of the whole-brain voxel-by-voxel fMRI connectivity using multivariate distance-based matrix regression (MDMR) analysis to determine connectivity abnormalities without a priori hypothesis. PTSD veterans showed increased connectivity across sensory motor areas and the superior temporal to default mode network (DMN) areas compared to non-trauma-exposed control. Veterans without PTSD also showed altered connectivity in the bilateral insula compared to control. This abnormal connectivity pattern was normalized after real-time fMRI neurofeedback training focused on learning to control left amygdala activity with positive autobiographical memory recall.

4214

Computer 55

Substructural Volumes of the Thalamus in Alcoholism

Natalie M Zahr^{1,2} and Manojkumar Saranathan³

¹Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, United States, ²Neurosciences, SRI International, Menlo Park, CA, United States, ³Medical Imaging, Univ. of Arizona, Tucson, AZ, United States

Volumes of the thalamus and 4 thalamic substructures (i.e., anterior (AT), mediodorsal (MD), ventrolateral (VL), pulvinar (Pul)) were quantified using a novel automated segmentation algorithm in 18 individuals meeting criteria for Alcohol Use Disorders (AUD) and 28 healthy controls (Con). Multiple regressions considered contributions of diagnosis (i.e., Con vs. AUD), age, sex, and intracranial volume on substructural volumes. Volumes of AT, VL, and Pul were smaller with increasing age. Volumes of MD and Pul were affected by diagnosis: both were smaller in the AUD relative to the Con group. These results suggest that thalamic substructures have differential vulnerability to pathological processes.

Computer 56

Localized connectivity in obsessive-compulsive disorder: An insight from univariate and multivariate pattern analyses

Xinyu Hu¹, Ming Zhou¹, Lu Lu¹, Lianqing Zhang¹, Xiaoxiao Hu¹, Xuan Bu¹, Hailong Li¹, Yanchun Yang², Qiyong Gong¹, and Xiaoqi Huang¹

¹Department of Radiology, Huaxi MR Research Center (HMRR), West China Hospital of Sichuan University, Chengdu, People's Republic of China, ²Department of Psychiatry, Mental Health Center, West China Hospital of Sichuan University, Chengdu, People's Republic of China

The current study, for the first time, integrated voxel-wise univariate analysis and multivariate pattern classification approach to evaluate the alterations of localized neural connectivity in a relatively large sample of drug-naïve patients with obsessive-compulsive disorder (OCD). Our findings (i) suggested the disequilibrium between the fronto-parietal circuit and the cerebellum might be associated with the pathophysiology of OCD, (ii) indicated the translational role of the localized neural connectivity as a potential discriminative pattern to identify OCD at the individual level and (iii) highlighted the hyperactivation of the prefrontal cortex in the pathophysiologic process of OCD.

4216

Computer 57

The ability of magnetic resonance spectroscopy to measure metabolite changes in response to ketamine in major depression at 7T

Jennifer Evans¹, Niall Lally¹, Li An¹, Allison Nugent¹, and Carlos Zarate¹

¹NIMH, NIH, Bethesda, MD, United States

This study investigates the feasibility of measuring glutamate and glutamine metabolites by 7T 1H-MRS after a ketamine infusion in a double blind placebo cross-over study in major depression. MRS data was acquired from the pre-genual anterior cingulate in 15 depressed and 13 healthy controls. Glutamate levels, but not glutamine, were found to be significantly different between groups.

4217

Computer 58

Aberrant fronto-limbic effective connectivity during repeated fearful face stimuli in body dysmorphic disorder and anorexia nervosa

D Rangaprakash^{1,2}, Nathan L Hutcheson¹, Katherine E Lawrence¹, Teena D Moody¹, Sarah Madsen^{1,3}, Sahib Khalsa^{1,4,5}, Michael Strober¹, Cara Bohon⁶, and Jamie D Feusner¹

¹Department of Psychiatry and Biobehavioral Sciences, University of California Los Angeles, Los Angeles, CA, United States, ²AU MRI Research Center, Department of Electrical and Computer Engineering, Auburn University, Auburn, AL, United States, ³Imaging Genetics Center, Department of Neurology, University of Southern California, Los Angeles, CA, United States, ⁴Oxley College of Health Sciences, University of Tulsa, Tulsa, OK, United States, ⁵Laureate Institute for Brain Research, University of Tulsa, Tulsa, OK, United States, ⁶Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, United States

Anorexia nervosa (AN) and body dysmorphic disorder (BDD) share distorted perception of appearance, anxiety, and depression, yet their common and distinguishing neural phenotypes of emotion processing remain unknown. To address this, we studied fronto-limbic connectivity using functional MRI data obtained while participants (N=94) viewed fearful faces and rated their own subjectively experienced fearfulness. Healthy controls exhibited, as predicted, significant bidirectional medial prefrontal (mPFC)-amygdala connectivity, which increased across blocks. However, BDD participants exhibited significant mPFC-to-amygdala but not amygdala-to-mPFC connectivity (indicating limbic hypo-responsiveness), while AN exhibited no significant prefrontal-amygdala connectivity. This study suggests distinct, aberrant fronto-limbic modulatory connectivity in AN and BDD.

Accumulation of Prefrontal Lactate Levels in Chronic Schizophrenia

Lijing Xin¹, Philipp S Baumann^{2,3}, Raoul Jenni^{2,3}, Luis Alameda^{2,3}, Carina Ferrari^{2,3}, Philippe Conus³, Rolf Gruetter^{4,5}, and Kim Q Do²

¹Center for Biomedical Imaging (CIBM), Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ²Unit for Research in Schizophrenia, Center for Psychiatric Neuroscience, Department of Psychiatry, Lausanne University Hospital (CHUV), Lausanne, Switzerland, ³Service of General Psychiatry, Department of Psychiatry, Lausanne University Hospital (CHUV), Lausanne, Switzerland, ⁴Laboratory of Functional and Metabolic Imaging, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ⁵Departments of Radiology, University of Lausanne and Geneva, Lausanne and Geneva, Switzerland

Mitochondrial dysfunction including altered brain energy metabolism has been implicated in the pathophysiology of schizophrenia. The aim of this study was to investigate prefrontal lactate(Lac) levels in patients with chronic schizophrenia. An increase of [Lac_{mPFC}] was observed in patients with chronic schizophrenia relative to healthy controls. This may be associated with glucose metabolism impairment and mitochondrial dysfunction resulting from oxidative stress. Indeed, oxidative damages can impair mitochondrial oxidative phosphorylation and enzyme activities of pyruvate dehydrogenase, leading to Lac production. Therefore, this study provides in vivo evidence supporting that oxidative stress and mitochondrial dysfunction may be involved in schizophrenia.

Brain Cortical Thickness in Adolescents from Multiplex Alcohol Dependence Families

Bharath Holla¹, Rajanikanth Panda², Ganesan Venkatasubramanian³, Rose Dawn Bharath², and Vivek Benegal¹

¹Centre for Addiction Medicine and Department of Psychiatry, National Institute of Mental Health & Neuro Sciences (NIMHANS), Bangalore, India, ²Cognitive Neuroscience Centre and Department of Neuroimaging and Interventional Radiology (NIIR), National Institute of Mental Health & Neuro Sciences (NIMHANS), Bangalore, India, ³Translational Psychiatry Laboratory and Department of Psychiatry, National Institute of Mental Health & Neuro Sciences (NIMHANS), Bangalore, India

Adolescents with high familial-loading of alcoholism exhibit altered premorbid subcortical and cerebellar brain-volumes compared to their peers. They also differ in brain-activity during executive-functioning, reward, and emotion-processing tasks. However, the changes in the maturation of the cortical thickness during the adolescence in these high-risk (HR) individuals and their relationship with the externalizing-behaviors have never been examined. Our findings reveal wide-spread delays in cortical maturation in HR subjects, which may ultimately contribute to their addiction vulnerability. More importantly, these effects reduce with age by late-adolescence in the absence of substance-misuse. Additionally, cortical thinning was associated with better behavioral control across groups

4220

Computer 61

Proton magnetic resonance spectroscopy study of amygdala, anterior cingulate cortex and thalamus in pediatric post-traumatic stress disorder patients

Weina Wang¹, Xiaorui Su², Qiyong Gong², and Qiang Yue²

¹Department of Radiology, West China Hospital of Sichuan University, Chengdu, People's Republic of China, ²West China Hospital of Sichuan University, People's Republic of China

PTSD is associated with a variety of structural and functional brain abnormalities, but the molecular pathophysiological mechanisms are unknown. 25 pediatric PTSD and 24 matched healthy control subjects underwent single voxel 1H-MRS. Right amygdala NAA was significantly increased in pediatric PTSD subjects than in controls, and the other metabolites did not differ significantly between the groups. We hypothesize that long-term excessive activation in amygdala after traumatic events may lead to increase density and activity of the neurons in pediatric PTSD patients with increased NAA concentration, which may be an adaptive response to traumatic stimulation in the human brain. Our findings add the neurochemical abnormality evidence in pediatric PTSD.

4221

Computer 62

Disruptions in T1-weighted MRI signal trajectories over age in Bipolar Disorder Type-1

Christopher Dennis Rowley¹, Manpreet Sehmbi¹, Luciano Minuzzi², Benicio Frey², and Nicholas Bock³

¹Neuroscience, McMaster University, Hamilton, ON, Canada, ²Psychiatry and Behavioural Neurosciences, McMaster University, Hamilton, ON, Canada, ³Psychology, Neuroscience & Behaviour, McMaster University, Hamilton, ON, Canada

T₁-weighted signal is known to be correlated with age and myelin content. T₁-weighted images with optimized intracortical contrast were taken in subjects aged 17-45. The half cortical depth signal was mapped in 67 healthy controls and 43 individuals diagnosed with bipolar disorder type-1. We investigated the trajectory of the signal with age in each group and it was found that healthy signal trajectory follows a quadratic form with age, while no correlation with age was found in bipolar disorder. We have shown that it is possible to map signal trajectory changes in clinical populations across the cortex.

4222

Computer 63

Resting-state functional connectivity abnormalities associated with posttraumatic stress disorder and traumatic stress: a graph-based analysis
Lei Li¹, Xinyu Hu¹, Xiaoqi Huang¹, and Qiyong Gong¹

¹Department of Radiology, Huaxi MR Research Center, Chengdu, People's Republic of China

Previous studies have clarified that differentiating the disease- and traumatic stress-related brain changes may elucidate the core neural mechanism of PTSD. This study is to investigate brain functional alterations in PTSD and the traumatic exposed controls (TEC) relative to the non-traumatized healthy controls (HC) separately, using a data-driven graph theoretical approach—whole-brain functional connectivity strength (FCS) mapping. The current study provided the preliminary evidence of common and separate abnormalities of neural correlates at whole-brain level associated with PTSD and traumatic stress. The disequilibrium between the DMN and the SN might be associated with the pathophysiology of PTSD.

4223

Computer 64

Discrimination of patients with first episode schizophrenia via quantitative cortical morphology features and machine learning methods
Huaiqiang Sun¹, Ying Chen¹, Haoyang Xing¹, Su Lui¹, and Qiyong Gong¹

Detailed T1-weighted laminar profiles from the human cortex measured in vivo at 3T and validated at 7T

Bart Ferguson¹, Natalia Petridou², Alessio Fracasso^{2,3}, Martijn P Van den Heuvel¹, Rachel M Brouwer¹, Hilleke E Hulshoff Pol¹, Rene S Kahn¹, and Rene C W Mandl^{1,4}

¹Psychiatry, UMC Utrecht, Utrecht, Netherlands, ²Radiology, UMC Utrecht, Utrecht, Netherlands, ³Experimental Psychology, Utrecht University, Utrecht, Netherlands, ⁴CNSR, Psykiatrisk Center Glostrup, Glostrup, Denmark

Patients with schizophrenia show cortical gray matter thinning but it is unknown whether all six cortical layers are implicated or that specific layers are affected. Knowing which layers are involved gives more insight in the underlying pathophysiological processes of schizophrenia. Here we present a method to compute detailed laminar profiles per brain area from conventional 3T T1-weighted scans, which can be used to obtain information on relative layer organization. We validate this method by comparing average profiles computed from conventional 3T scans to profiles computed from high resolution scans, acquired at ultra-high field MRI (7T).

Computer 66

The acute pharmacological MRI response to a citalopram challenge is modulated by earlier selective serotonin reuptake inhibitor exposure in an age dependent manner

Michelle Solleveld^{1,2}, Anouk Schrantee¹, Henk-Jan Mutsaerts^{1,3}, Paul Lucassen², and Liesbeth Reneman¹

¹Department of Radiology, Academic Medical Center Amsterdam, Amsterdam, Netherlands, ²Swammerdam Institute for Life Sciences, Center for Neurosciences, University of Amsterdam, Amsterdam, Netherlands, ³Sunnybrook Research Institute, University of Toronto, Toronto, Canada

Preclinical studies have shown that selective serotonin reuptake inhibitor (SSRI) treatment, when applied to the developing brain, is associated with long-term changes in the adult serotonergic system. Using pharmacological MRI (phMRI), we here investigated whether SSRIs can also induce such age-dependent changes in the human serotonergic system. We found that the phMRI response to citalopram was decreased in the amygdala only in adult female subjects who had been first exposed to SSRIs early in life, whereas a blunted response was found in subjects first exposed at a later age.

4226

Computer 67

Utility of MR-Spectroscopy in Early Drug Discovery: Characterization of Psychiatric Dysfunctions & Psycho-active Drug Effects

Sakthivel Sekar¹, Joanes Grandjean¹, Joanne Garnell¹, Sankar Seramani¹, Marc Ceuster², Hilde Lavreysen², and Kishore Bhakoo¹

¹Singapore Bioimaging Consortium, Singapore, Singapore, ²Neuroscience Therapeutic Area, Janssen Pharmaceuticals R&D, Belgium

MR-Spectroscopy offers a unique potential to characterize underlying neuronal mechanisms of psychiatric dysfunctions and the effects of psychoactive drugs, at a fundamental neuro-metabolite level in-vivo. We studied two preclinical disease models: the chronic mild unpredictable stress (CMUS) model, a putative model for depression, and a sub-chronic memantine (NMDA antagonist) model, a putative model for psychosis using single voxel spectroscopy (SVS). Our results represents metabolic fingerprinting of dysfunctions utilising live metabolic flux profiling; documenting neuro-metabolic effects of novel psycho-active drugs, presenting novel insights in-vivo. Our results and unique approach, exemplifies the potential value of SVS in early stage drug discovery and its potential translation to clinical research.

4227

Computer 68

Altered causal connectivity of the anterior cingulate cortex in obsessive compulsive disorder

Fei Li¹, Su Lui¹, Li Yao¹, Xiaoqi Huang¹, Yanchun Yang², and Qiyong Gong¹

¹Huaxi MR Research Center (HMRR), Department of Radiology, West China Hospital of Sichuan University, Chengdu, People's Republic of China, ²Department of Psychiatry, West China Hospital of Sichuan University, Chengdu, People's Republic of China

In order to explore the role of anterior cingulate cortex (ACC) in the pathophysiology of obsessive-compulsive disorder (OCD), we used the resting-state functional magnetic resonance imaging (rfMRI) and Granger causality analysis (GCA) and found that the left pregenual ACC of OCD showed decreased amplitude of low-frequency fluctuation (ALFF) than controls. The areas with altered ALFF exhibited decreased driving effect to right dorsal superior frontal gyrus (dSFG) and left precuneus, and a significant increase in the causal influence from left ventral SFG (vSFG) to the left pregenual ACC in OCD compared to controls.

4228

Computer 69

Evaluation of abnormal structural changes in major depressive disorder with self-harm using generalized q-sampling MRI

Kung-Te Chu¹, Vincent Chin-Hung Chen^{2,3}, Te-Wei Kao¹, and Jun-Cheng Weng^{1,4}

¹Department of Medical Imaging and Radiological Sciences, Chung Shan Medical University, Taichung, Taiwan, ²School of Medicine, Chang Gung University, Taoyuan, Taiwan, ³Department of Psychiatry, Chang Gung Memorial Hospital, Chiayi, Taiwan, ⁴Department of Medical Imaging, Chung Shan Medical University Hospital, Taichung, Taiwan

Major depressive disorder (MDD) is a significant brain dysfunction that might cause self-harm behavior. The abnormal brain structures between MDD and healthy control have been investigated by using diffusion tensor imaging (DTI) in several studies. However, few studies discussed the brain structure changes in MDD patients with self-harm behavior. Moreover, there were some limitations in DTI. Therefore, our study aimed to find the abnormalities of neurological structure of white matter among MDD without self-harm behavior (MDD_N), MDD with self-harm behavior (MDD_S), and healthy control (HC), using generalized q-sampling imaging (GQI). We found the significant differences in the corpus callosum, superior longitudinal fasciculus (SLF), cingulum, and frontal lobe of GQI indices in individual groups.

Altered Hippocampus Microstructure in Schizophrenia: A Diffusional Kurtosis Imaging and Magnetic Resonance Spectroscopy Imaging Study

Mariana Lazar¹, Maia Boudzinskaia², Emma Meyer², Dolores Malaspina², James Babb¹, and Oded Gonen¹

¹Radiology, New York University School of Medicine, New York, NY, United States, ²Psychiatry, New York University School of Medicine, New York, NY, United States

Diffusional Kurtosis Imaging (DKI) and Magnetic Resonance Spectroscopy Imaging were employed to assess microstructural changes of hippocampus in patients with schizophrenia. Increased mean kurtosis and mean diffusivity were observed for both left and right hippocampi in patient compared to the control group. In patients, mean kurtosis showed a strong negative correlation with N-acetylaspartate concentration. These results suggest disorganized hippocampal microstructure, likely due to neuroinflammatory processes such as micro- and astrogliosis and/or disorganized neuronal domains. DKI's apparent sensitivity to microstructural deficits may ultimately be employed to identify individuals with microscopic hippocampal impairment.

Measuring Alanine in Schizophrenia using 2D Correlation Spectroscopy

Adrienne Lee¹, Luke Wang^{1,2}, Benjamin Rowland¹, Vicky Liao¹, Elisabetta Del Re³, Robert McCarley³, and Alexander Lin¹

¹Center for Clinical Spectroscopy, Brigham and Women's Hospital, Boston, MA, United States, ²Department of Anesthesiology, Perioperative and Pain Medicine, Boston Children's Hospital and Harvard Medical School, Boston, MA, ³Laboratory of Neuroscience, Veterans Affairs Boston Healthcare System, Boston, MA

Degree of schizophrenia (SZ) was determined by phase-locking factor (PLF) acquired through an electroencephalogram (EEG). Correlation spectroscopy (COSY) spectra of the chronic SZ patients and age-matched healthy controls were then compared. A significant difference ($p < 0.05$) between SZ and controls was found in the concentrations of alanine supported by a strong correlation between PLF and alanine levels. These results suggest further studies to examine alanine as a potential biomarker for schizophrenia.

Computer 72

Regional Brain Volume Changes in Alcohol-dependent Individuals during Short-term and Long-term Abstinence

Xiaowei Zou^{1,2}, Timothy C. Durazzo^{3,4}, and Dieter J. Meyerhoff^{1,2}

¹Department of Radiology and Biomedical Imaging, University of California San Francisco, San Francisco, CA, United States, ²Center for Imaging of Neurodegenerative Diseases, San Francisco VA Medical Center, San Francisco, CA, United States, ³Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, United States, ⁴Mental Illness Research and Education Clinical Centers and Sierra-Pacific War Related Illness and Injury Study Center, VA Palo Alto Health Care System, CA, United States

The general goal of this study is to determine the volume changes of cortical and subcortical brain regions in smoking and currently non-smoking alcohol-dependent individuals during short-term and long-term abstinence from alcohol, compared with non-/light-drinking controls. Preliminary results from paired t-tests within each group show that the anterior cingulate cortex, dorsolateral prefrontal cortex, orbitofrontal cortex, insula, and hippocampus have different recovery patterns, which suggest potentially different neuropathological changes and/or injuries. More statistical analyses will test for cross-sectional and longitudinal differences between the groups for a better interpretation of the regional volume changes and their cognitive and behavioral correlates.

RAFF, T1p and T2p mapping of human gliomas: association with IDH mutation, 1p19q co-deletion and Ki67

Harri Merisaari^{1,2,3}, Ivan Jambor^{3,4}, Marko Pesola^{3,4}, Maria Gardberg⁵, Janek Frantzén⁶, Pekka Jokinen⁶, Hannu Aronen^{3,4}, Timo Liimatainen^{7,8}, Heikki Minn⁹, and Aida Kiviniemi^{3,4}

¹Turku PET Centre, University of Turku, Turku, Finland, ²Department of Information Technology, University of Turku, Turku, Finland, ³Medical Imaging Centre of Southwest Finland, Turku University Hospital, Turku, Finland, ⁴Department of Diagnostic Radiology, University of Turku, Turku, Finland, ⁵Department of Pathology, University of Turku and Turku University Hospital, Turku, Finland, ⁶Division of Clinical Neurosciences, Department of Neurosurgery, Turku University Hospital, Turku, Finland, ⁷Department of Biotechnology and Molecular Medicine, A.I. Virtanen Institute for Molecular Sciences, University of Eastern Finland, Kuopio, Finland, ⁸Diagnostic Imaging Center, Kuopio University Hospital, Kuopio, Finland, ⁹Department of Oncology and Radiotherapy, Turku University Hospital, Turku, Finland

Our aim was to study the feasibility of quantitative RAFF, T1p_{cw}, T1p_{adiab} and T2p_{adiab} imaging for the first time in human gliomas and to assess their ability to differentiate gliomas with specific genetic profile. FLAIR lesion segmentation and histogram analysis from parametric maps were applied. Both IDH mutated and 1p19q codeleted gliomas demonstrated a tendency for lower relaxation values compared to IDH wild-type and 1p19q intact gliomas, respectively. Additionally, T2p_{adiab} significantly correlated to Ki-67 and tumor aggressiveness. We conclude that RAFF, T1p_{cw}, T1p_{adiab} and T2p_{adiab} imaging of gliomas is feasible and carry a potential for improving non-invasive glioma characterization.

Detecting treatment response of a novel immune stimulator in an animal model of glioblastoma with conventional and cell tracking MRI

Runze Yang¹, Susobhan Sarkar², V. Wee Yong², and Jeff F Dunn^{1,2}

¹Radiology, University of Calgary, Calgary, AB, Canada, ²Clinical Neuroscience, University of Calgary

Glioblastoma Multiforme (GBM) is an aggressive brain cancer. Immunotherapy is a promising avenue of exploration for treatment of GBM. We discovered a new drug capable of stimulating innate immunity and showed that it is able of reducing tumor growth in a mouse model of GBM. We used ultrasmall iron oxide nanoparticles (USPIO) to track the migration of stimulated immune cells and showed that this drug related response can be detected with as little as 7 days of treatment. MRI tracking of immune cells using USPIO is a promising tool that can be easily translated into the clinical setting.

Metabolic imaging with Gallium-68 citrate PET and 3D MRSI in patients with glioma

Yan Li¹, Spencer Behr¹, Susan Chang², Sarah J Nelson¹, and Michael Evans¹

¹Department of Radiology and Biomedical Imaging, University of California San Francisco, San Francisco, CA, United States, ²Department of Neurological Surgery, University of California San Francisco, San Francisco, CA, United States

This study evaluated the feasibility of using combined metabolic imaging methodologies, namely 3D lactate-edited proton magnetic resonance spectroscopic imaging and Gallium-68 citrate PET, in patients with glioma using a PET/MR scanner.

4235

Computer 76

MRI Signal Enhancement in Early-Stage GBM Detection by Nonlinear Spin Dynamics using Active Feedback Fields

Huimin Yang¹, Chaohsiung Hsu², and Yung-Ya Lin¹

¹Chemistry and Biochemistry, University of California, Los Angeles, Los Angeles, CA, United States, ²Chemistry, National Taiwan University, Taipei, Taiwan

Application of MR imaging is very limited in imaging sensitivity and contrast in regards to the detection of brain tumor at an early stage because of tiny variations between healthy tissue and early-stage tumor. The radiation damping effect provides insight about the nonlinear spin evolution. Taking advantage of nonlinear spin evolution, we confirmed theoretically and experimentally that MR imaging provides a more stable and significant contrast in comparison to conventional methods.

Computer 77

Ferumoxylol Iron Nanoparticle Enhanced MR Imaging is a Noninvasive Biomarker of Isocitrate Dehydrogenase Mutational Status in Recurrent Glioblastoma and Pseudoprogression

Ramon Francisco Barajas Jr^{1,2}, Bronwyn E Hamilton¹, David R Pettersson¹, Daniel L Schwartz^{2,3}, Jenny Firkins³, Prakash Ambady³, Andrea Horvath³, Heather L McConnell³, Joao Prola-Netto^{1,3}, Csanad Varallyay^{1,3}, Jerry J Jaboin⁴, Charlotte D Kubicky⁴, Ahmed M Raslan⁵, Aclan Dogan⁵, Jeremy Ciporen⁵, Leslie L Muldoon³, William Rooney², and Edward A Neuwelt^{3,5}

¹Radiology, Oregon Health & Science University, Portland, OR, United States, ²Advanced Imaging Research Center, Oregon Health & Science University, Portland, OR, United States, ³Neurology, Oregon Health & Science University, Portland, OR, United States, ⁴Radiation Medicine, Oregon Health & Science University, Portland, OR, United States, ⁵Neurological Surgery, Oregon Health & Science University, Portland, OR, United States

Ferumoxylol iron nanoparticles are used as an off label molecular MR imaging contrast agent in patients with reduced renal function precluding gadolinium administration. Glioblastoma molecular features are now recognized as an integral component of glioma pathogenetic classification and clinical outcome. IDH1 mutation accounts for approximately 10% of glioblastoma. The absence of a reliable noninvasive biomarker of glioblastoma IDH mutation prompted this retrospective study to determine if Ferumoxylol MR Imaging is diagnostic of IDH mutational status. We observed that the presence of increased Ferumoxylol to Gadolinium enhancing ratio was a significant 3T MR imaging biomarker for IDH mutational status in recurrent glioblastoma and the differentiation of pseudoprogression.

4237

Standard DICOM Structured Reports as a Vehicle for Multi-Modal Region-of-Interest MR Analysis Results for Clinical Workflows and Radiomic Studies for Brain Tumor Patients

Marram P Olson¹, Jason C Crane¹, Janine Lupo¹, Marisa Lafontaine¹, and Sarah J Nelson¹

¹Radiology and Biomedical Imaging, UCSF, San Francisco, CA, United States

Quantitative analysis of metabolic and dynamic imaging data produces maps of parameters that show promise for improving medical diagnosis and therapeutic monitoring for patients with brain tumors. Statistical ROI analysis of these maps can be used to quantitatively summarize multi-modality imaging metrics and longitudinal changes. In this work we demonstrate a standards-based mechanism for generating and communicating minable, quantitative Region of Interest (ROI) analysis results that can easily be integrated into clinical workflows and radiomic studies.

4238

Computer 79

Prediction of IDH Mutation Status of Diffuse-Gliomas Based on Short-Echo Time Magnetic Resonance Spectroscopy at 3T

Esin Ozturk-Isik¹, Sevim Cengiz¹, Koray Ozduman^{2,3}, Alpay Ozcan^{3,4}, Cengiz Yakicier⁵, M. Necmettin Pamir^{2,3}, and Alp Dincer^{3,6}

¹Institute of Biomedical Engineering, Bogazici University, Istanbul, Turkey, ²Department of Neurosurgery, Acibadem University, Istanbul, Turkey, ³Neuroradiology Research Center, Acibadem University, Istanbul, Turkey, ⁴Department of Medical Engineering, Acibadem University, Istanbul, Turkey, ⁵Department of Molecular Biology and Genetics, Acibadem University, Istanbul, Turkey, ⁶Department of Radiology, Acibadem University, Istanbul, Turkey

The tumor biology of diffuse-gliomas is best reflected by their molecular profile. Isocitrate dehydrogenase (IDH) mutation status has the strongest correlation to treatment response and patient survival among all molecular markers. The aim of this study is to predict IDH mutation status of gliomas based on short-echo time MR spectroscopic (MRS) biomarkers by using machine learning algorithms at 3T. Our results indicated that MRS based biomarkers were able to discriminate between IDH-mutant and IDH-wild type patients with up to 91% sensitivity, %78 specificity, and 86.9% accuracy by using an ensemble of bootstrap-aggregated decision trees classification with a three-fold cross validation.

4239

Computer 80

Minimizing the confounding effect of gadolinium contrast on subsequent ferumoxylol MRI in the brain

Csanad Gyorgy Varallyay¹, Andrea Horvath², Gerda Toth², Laszlo Szidonya², Emily Youngers², and Edward Neuwelt³

¹Dept. of Radiology, Oregon Health and Science University, Portland, OR, United States, ²Oregon Health and Science University, Portland, OR, United States, ³Dept. of Neurology, Oregon Health and Science University, Portland, OR, United States

Ferumoxylol as an MRI contrast agent has the advantage of long intravascular phase and strong transverse relaxivity, allowing high resolution depiction of abnormal vasculature and steady state blood volume (SS-CBV) mapping. In clinical studies it would be beneficial to use ferumoxylol as an immediate extension of standard of care gadolinium enhanced MRI, instead of imaging on two separate days. This study concludes that the 3D T2* weighted acquisition has substantial T1 weighting, while the 2D acquisition does not, therefore the latter one is preferable for ferumoxylol vascular imaging if gadolinium is on board.

4240

Computer 81

Comparison of gadoterate meglumine and gadobutrol in MRI diagnosis of brain tumors: a double-blind randomized intra-individually controlled in cross-over study (the REMIND study)

Kenneth Maravilla¹, Daniel San Juan Orta², Sang Joon Kim³, and Guillermo Elizondo Riojas⁴

¹Radiology, University of Washington, Seattle, WA, United States, ²Clinical Research Institute S.C., Tlanepantla de Baz, Mexico, ³Asan medical center / Radiology, Seoul, Korea, Democratic People's Republic of, ⁴Universidad Autonoma de Nuevo Leon, Hospital Universitario Dr. Jose Eleuterio Gonzalez, Monterrey, Mexico

This double-blind randomized cross-over study was conducted to demonstrate non-inferiority of gadoterate meglumine vs. gadobutrol in MRI diagnosis of brain tumors. Images from two identical MRIs with each agent were evaluated by three independent off-site readers. Overall lesion visualization and characterization was scored as "good" or "excellent" in >90% of patients by all readers. Despite a small difference in signal intensity measurements in favor of gadobutrol, similar results were observed with the two agents regarding overall lesion visualization and characterization or qualitative efficacy criteria. Non-inferiority of gadoterate meglumine vs. gadobutrol in diagnosis of brain tumors by MRI was demonstrated.

4241

Computer 82

[23Na-MRI demonstrates a sodium gradient within gliomas as a biomarker of tumor heterogeneity](#)

Fulvio Zaccagna¹, Frank Riemer¹, Mary A. McLean², James T. Grist¹, Joshua Kaggie¹, Rolf F Schulte³, Sarah Hilborne¹, Tomasz Matys¹, Jonathan H. Gillard¹, Colin Watts⁴, Stephen J. Price⁴, Martin J. Graves¹, and Ferdia A. Gallagher¹

¹Department of Radiology, University of Cambridge, Cambridge, United Kingdom, ²Cancer Research UK Cambridge Institute, University of Cambridge, Cambridge, United Kingdom, ³GE Global Research, Munich, Germany, ⁴Neurosurgery Unit, Department of Clinical Neurosciences, University of Cambridge, Cambridge, United Kingdom

Glioma grade and the extent of local infiltration are important factors for guiding management. Imaging tumor heterogeneity may also improve diagnosis and therapy planning. ²³Na-MRI has been used here to demonstrate a gradient in sodium concentration across gliomas: necrosis greater than viable tissue greater than edema. This gradient was evident in all 17 tumors analyzed and is consistent with the expected underlying histopathology; concentration is increasing throughout the evolution from edema, dominated by the extracellular compartment, to the necrotic core, dominated by dead cells and broken sodium pumps. ²³Na-MRI may therefore represent an imaging biomarker of tumor heterogeneity in glioma.

[Spectroscopic Imaging-based detection of 2-hydroxyglutarate \(2HG\) in IDH1 mutant human gliomas on 3T Clinical](#)

Gaurav Verma¹, Sanjeev Chawla¹, Harish Poptani², MacLean Nasrallah³, Michael Albert Thomas⁴, Arati Desai⁵, Steven Brem⁶, and Suyash Mohan⁷

¹Neuroradiology, University of Pennsylvania, Philadelphia, PA, United States, ²Cellular and Molecular Physiology, University of Liverpool, Liverpool, United Kingdom, ³Pathology, University of Pennsylvania, Philadelphia, PA, United States, ⁴Radiology, University of California Los Angeles, Los Angeles, CA, United States, ⁵Hematology Oncology, University of Pennsylvania, Philadelphia, PA, United States, ⁶Neurosurgical Oncology, University of Pennsylvania, Philadelphia, PA, United States, ⁷Radiology, University of Pennsylvania, Philadelphia, PA, United States

Mutations in isocitrate dehydrogenase (IDH) play an increasing role in clinical assessment of human gliomas and determination of treatment. The performance of Chemical Shift Imaging (CSI) to detect 2-hydroxyglutarate (2HG) in mutant-IDH gliomas was assessed in the routine clinical environment. Specificity of 80% and sensitivity of 63% was achieved in a cohort of 15 patients scanned with the technique at 3T. Greater sensitivity, through longer acquisition or more sensitive equipment could result in reliable non-invasive detection of this putative biomarker present in a majority of Grade II/III gliomas.

Computer 85

[Differentiation of Radiation Necrosis from Tumour Progression Using Chemical Exchange Saturation Transfer \(CEST\)](#)

Hatef Mehrabian^{1,2}, Hany Soliman³, Arjun Sahgal³, and Greg J Stanisz²

¹Radiology and Biomedical Imaging, University of California, San Francisco, San Francisco, CA, United States, ²Physical Sciences, Sunnybrook Research Institute, Toronto, ON, Canada, ³Radiation Oncology, Sunnybrook Research Institute, Toronto, ON, Canada

Radiation necrosis is the most common side-effect of stereotactic radiosurgery (SRS) and has similar characteristics to tumor progression on standard anatomical MRI. Differentiating these two conditions is a major long standing clinical challenge. In this study the potential of chemical exchange saturation transfer (CEST) in differentiating the two conditions in patient with brain metastases is investigated. The results showed that the magnetization transfer ratio (MTR) of amide and NOE peaks provided the best separation of radiation necrosis cases from tumor progression cases. However, the commonly used amide proton transfer (APT) was unable to differentiate the two conditions.

4245

Computer 86

[High resolution 7 T magnetic resonance spectroscopic imaging of glioma in the brain](#)

Gilbert Hangel¹, Eva Heckova¹, Bernhard Strasser¹, Michal Považan^{1,2}, Stephan Gruber¹, Elisabeth Springer¹, Georg Widhalm³, Matthias Preusser⁴, Siegfried Trattnig^{1,2}, and Wolfgang Bogner^{1,2}

¹High Field MR Centre, Medical University of Vienna, Vienna, Austria, ²Christian Doppler Laboratory for Clinical Molecular MR Imaging, Vienna, Austria, ³Department of Neurosurgery, Medical University of Vienna, ⁴Department of Medicine I, Division of Oncology, Medical University of Vienna

We present the application of single-slice high-resolution FID-MRSI with short acquisition delay at 7T that provides whole-slice metabolite maps in eight patients with different types of glioma. With six minutes measurement time, it could be easily integrated into a standard imaging protocol. The results show that it is possible to resolve metabolic deviations in an extended number of biochemical compounds in tumors with unprecedented spatial details, thereby offering deeper insight into the neurochemical profiles of different glioma types. This suggests that the demonstrated method has a high potential for the research of glioma.

Computer 87

Detection 2-Hydroxyglutarate in IDH-Mutant Gliomas using TE-Averaged PRESS at 3T
Vivek TIWARI¹, Sandeep Ganji, ZhongXu An, and Changho Choi

¹UT Southwestern Medical Center, Dallas, TX, United States

Gliomas harboring mutations in Isocitrate-Dehydrogenase (IDH) 1/2 exhibits a neomorphic-activity resulting in production of 2-hydroxyglutarate (2HG) by 2-3 orders of magnitude. Non-invasive detection of 2HG using conventional 1H Magnetic Resonance Spectroscopy (MRS) is challenging due to extensive overlap with the resonances of neighboring metabolites. Here we have designed a TE-Averaged PRESS 1H-MRS that reduces the spectral-overlaps of GABA, Gln, Glu and glutathione signals on 2HG-2.25ppm-resonance that provides a reliable-detection of 2HG. We have also estimated T2 in each brain-tumor by taking the advantage of multiple-TEs used in TE-averaging acquisitions, and used patient-specific T2 for estimation of 2HG.

Characterizing CRT-Induced Vascular Injury in the Developing Brain

Melanie A Morrison¹, Erin Felton², Angela Jakary¹, Andrew Leynes¹, Peder Larson¹, Sabine Mueller², and Janine Lupo¹

¹Radiology & Biomedical Imaging, University of California San Francisco, San Francisco, CA, United States, ²Neurology, University of California San Francisco, CA, United States

In the treatment of pediatric medulloblastomas, cranial radiation therapy (CRT) may induce long-term effects including CRT-induced vascular injury and cognitive impairments. 7T Susceptibility-weighted MRI was used to characterize CRT-induced injury in the form of cerebral microbleeds (CMBs) as potential markers of cognitive deficits. The majority of CMBs were located in the frontal lobe, which develop late in the adolescent brain. CMB density was associated with deficits in working and visual memory as a function of time since CRT. This work supports a modification of future standards for defining radiation target volumes, with evidence for early intervention with cognitive rehabilitation strategies.

4248

Computer 89

Optimizing Statistical Texture Model to Improve the Classification Accuracy of Tumor Grade in Glioma Patients with Machine Learning Based on Multimodality MR Images

Yang Yang¹, Lin-Feng Yan¹, Xin Zhang¹, Hai-Yan Nan¹, Yu-Chuan Hu¹, Yu Han¹, Jin Zhang¹, Wen Wang¹, and Guang-Bin Cui¹

¹Tangdu Hospital, Fourth Military Medical University, Xi'an, People's Republic of China

Texture analysis is a powerful image analysis method to assess the heterogeneous distribution of tumor quantitatively. Different statistical models have been applied in texture analysis to classify glioma grade and level. It has not been evaluated that which model is the most efficient. The aim of this study is to compare four texture models in glioma grading. Texture features were extracted from multimodality MR images in 3D ROIs. After machine learning and leave-one-out cross validation, the gray-level run-length matrix was found as the best model while gray-level was set as 256.

4249

Computer 90

Texture analysis of quantitative ADC maps to differentiate low from high grade glioma

Yingqiu Liuyang¹, Jin Shang¹, Yanwei Miao¹, Shesnia Salim Padikkalaky Cheryath¹, and Yan Guo²

¹First Affiliated Hospital of Dalian Medical University, Dalian, People's Republic of China, ²GE Healthcare, Lifescience, China

The objective of this study, was to differentiate low from high grade glioma using texture analysis of quantitative ADC maps, and further aimed at revealing the microscopic changes of glioma in the evolution of low grade to high grade. Conclusion that texture analysis of ADC signal value based on entire tumor could provide more information in differentiation of low and high grade glioma. Through logistic regression analysis we obtain skewness, entropy, long run emphasis are the independent influence factors, and joint application of them showed superior diagnostic value.

4250

A morphological classification of primary central nervous system lymphoma: new insights of the imaging analysis to facilitate treatment planning

Jing Liu^{1,2}, Kannie W.Y. Chan³, Bin Zhang¹, Guan Shu Liu², and Shui Xing Zhang¹

¹Department of Radiology, Guangdong Academy of Medical Sciences/Guangdong General Hospital, Guangzhou, People's Republic of China, ²Russell H. Morgan Department of Radiology and Radiological Sciences, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ³Department of Mechanical and Biomedical Engineering, City University of Hong Kong, Hong Kong, People's Republic of China

A preliminary classification of primary central nervous system lymphoma (PCNSL) was reported based on the MRI radiographical features. We classified the 90 PCNSL patients based on the T1 contrast-enhanced MRI findings and assessed treatment responses. The goal is to provide some guidelines and additional information for diagnosis and treatment planning. We categorized these patients into four distinctive types of PCNSL according to the T1 findings and observed the treatment response rate, which we found the highest in type Ia. This could potentially facilitate the diagnosis and treatment plan of PCNSL in a routine clinical setting.

4251

Computer 92

Radiogenomic analysis of distinct tumor sub-compartments on T2 and FLAIR predict distinct molecular subtypes in Lower Grade Gliomas

Niha Beig¹, Ramon Correa¹, Prateek Prasanna¹, Jhimli Mitra¹, Armeya Nayate², Anant Madabhushi¹, and Pallavi Tiwari¹

¹Biomedical Engineering, Case Western Reserve University, Cleveland, OH, United States, ²Radiology, University Hospitals, Cleveland, OH, United States

The recent categorization of low-grade Glioma (LGG) has been modified based on the molecular aberrations associated with IDH mutations (IDHmut or IDH-WT) and 1p19q co-deletions (code1 or non-code1). We explored the utility of radiogenomic analysis to identify radiomics signatures (computer extracted features from MRI) that distinguish IDHmut code1, IDHmut noncode1, and IDH-WT LGG tumors on T2 and FLAIR sequences. Initial results indicate that radiomic features from non-enhancing regions on T2 and infiltrative edges on FLAIR can segregate the 3 subgroups. A non-invasive means of discerning molecular subtypes on MRI may allow clinicians to determine prognosis, and inform treatment strategy.

4252

Computer 93

Textural Analysis Tool for Grading of Astrocytoma on Quantitative Susceptibility Mapping

Yihao Yao¹, Ilhami Kovanlikaya², Ramin Jafari³, Yi Wang^{2,4}, and Wenzhen Zhu¹

¹Department of Radiology, Tongji Hospital, Tongji Medical College, Huazhong University of Science & Technology, Wuhan, People's Republic of China, ²Department of Radiology, Weill Cornell Medical College, New York, NY, United States, ³Department of Biomedical Engineering, Cornell University, Ithaca, NY, United States, ⁴Biomedical Engineering, Cornell University, Ithaca, NY, United States

The accuracy of grading astrocytic brain tumors using texture analysis (TA) on quantitative susceptibility mapping (QSM) was studied. For texture analysis training data set, most discriminant factor (MDF1) values were significantly different for low grade and high grade astrocytomas ($p < 0.01$), as well as Grade II and III, Grade II and IV, Grade III and IV ($p < 0.01$). For texture analysis test data set, 19/20 cases in differentiating low grade from high grade astrocytomas, 16/20 cases in Grade II, III and IV differentiation were correctly classified. TA promises to be a useful tool for grading astrocytoma on QSM.

4253

Computer 94

Voxel-based Multiparametric Analysis of Magnetic Resonance Imaging Data for Differentiating Recurrent Glioblastoma from Delayed Radiation Necrosis

Ra Gyoung Yoon¹, Ho Sung Kim², Myeong Ju Koh³, and Sang Joon Kim²

¹Radiology, Catholic Kwandong University International St. Mary's Hospital, Incheon, Korea, Republic of, ²Radiology and Research Institute of Radiology, Asan Medical Center, Seoul, Korea, Republic of, ³Jeju National University Hospital

We evaluated a volume-weighted voxel-based multiparametric (MP) clustering method as an imaging biomarker for differentiating recurrent glioblastoma from delayed radiation necrosis, comparing to the single imaging parameters of DWI, DSC and DCE perfusion MR. In an area under the receiver operating characteristic curve analysis, volume-weighted voxel-based MP clustering demonstrated better diagnostic accuracy for discriminating these two conditions than single imaging parameters. When performed with use of an optimal cutoff, volume-weighted voxel-based MP clustering improved the overall sensitivity. Therefore, quantitative analysis using volume-weighted voxel-based MP clustering is superior to single imaging parameter measurements for differentiating recurrent glioblastoma from delayed radiation necrosis.

Computer 95

Medulloblastomas in adults: An MRI radiogenomic approach to an extremely rare disease

Vera Catharina Keil¹, Monika Warmuth-Metz², Christina Reh¹, Jonas Enkirch¹, Torsten Pietsch³, Hans Heinz Schild¹, Elke Hattingen¹, and Peter Hau⁴

¹Radiology, University Hospital Bonn, Bonn, Germany, ²Institute for Diagnostic and Interventional Neuroradiology, University Hospital Wuerzburg, Wuerzburg, Germany, ³Institute for Neuropathology, University Hospital Bonn, Bonn, Germany, ⁴Wilhelm Sander-Therapieeinheit NeuroOnkologie and Clinic and Polyclinic for Neurology, University Hospital Regensburg, Regensburg, Germany

Medulloblastoma in adults is very rare and shows prognostically relevant histological and genetic subtypes. Within a nation-wide multicenter study, pre-surgical MRIs of 28 cases were analysed to identify imaging biomarkers, which may be used to non-invasively predict these subtypes based on a radiophenotype. Molecular genetic subtypes SHH p53wt, WNT and non-WNT/non-SHH (Group 4) were significantly distinct in their relation to the 4th ventricle and lower rhombic limb, and extent of edema. Further imaging biomarkers could be identified that differentiate histological subtypes and nuclear- β -catenin expression patterns. Imaging biomarkers were not congruent to markers identified in pediatric patients implying possible age-related differences.

Enhanced Quality of Myelin Water Fraction Mapping from GRASE Imaging Data of Human Brain using a New Nonlocal Estimation of multi-Spectral Magnitudes (NESMA) Filter

Mustapha Bouhrara¹, Michael C. Maring¹, David A. Reiter¹, Jean-Marie Bonny², and Richard G. Spencer¹

¹NIA, National Institutes of Health, Baltimore, MD, United States, ²QuaPa, INRA, Clermont-Ferrand, France

Changes in myelin water fraction (MWF) represent a biomarker for central nervous system disease. However, high quality mapping of MWF is challenging, requiring very high signal-to-noise ratio for accurate and stable results. In this work, we demonstrate the potential of a new multispectral filter to permit high quality MWF mapping using in-vivo GRASE brain imaging datasets. Indeed, unlike conventional averaging filters, our filter permits substantial reduction of the random variation in derived MWF estimates while preserving edges and small structures. Finally, our results regarding patterns of MWF as a function of age are consistent with recent literature.

4257

Computer 98

Quantitative cerebral arteriolar vasomotor function mapping by spectral analysis of time series MR signal fluctuations

Minghui Tang¹, Keigo Nishi², and Toru Yamamoto¹

¹Faculty of Health Sciences, Hokkaido University, Sapporo, Japan, ²Department of Radiology, National Hospital Organization Hokkaido Medical Center, Sapporo, Japan

Cerebral arteriolar vasomotor function would be a biomarker for early diagnosis of dementia. We developed a quantitative mapping technique for cerebral arteriolar vasomotor function without administering any agents. The natural respiratory fluctuation of CO₂ in arterial blood was used, which alters cerebral blood flow and venous blood oxygenation, and hence modulates the MRI signal. This new technique is based on our finding of a strong correlation in MR signals between the cardiac fluctuation in brain parenchyma and the respiratory fluctuation at the sagittal sinus. Using this new mapping technique, the degeneration of arteriolar vasomotor function associated with aging was observed.

Cardiovascular risk factors, cerebral blood flow, and cognitive functions: preliminary results in a community based study in Chinese elders

Xin Hong¹, Sei Hwan Oh¹, Ying Hwey Nai¹, Saima Hilal^{2,3}, Suz-Chieh Sung¹, Mohammad Kamran Ikram^{3,4}, Christopher Chen^{2,3}, and Kai-Hsiang Chuang¹

¹Singapore Bioimaging Consortium, Agency for Science Technology and Research, Singapore, Singapore, ²Department of Pharmacology, National University of Singapore, ³Memory Aging & Cognition Centre, National University of Singapore, ⁴Singapore Eye Research Institute, Singapore National Eye Center

Cerebral blood flow (CBF) is an important biomarker of the brain function and has been shown to correlate with cognitive performance in diseases. Since cardiovascular and metabolic complications are common in elders, to understand the influence of vascular confound in cognitive correlation, we investigated how cardiovascular risk factors may affect the relationship between cognitive functions and CBF in non-demented elders. We found that mean arterial blood pressure, haematocrit, blood cholesterol and glucose levels had significant negative effects on CBF. This suggests that cardiovascular risk factors shall be taken into consideration when analyzing CBF in aging, cognitive impairment, and neurodegenerative diseases.

Oscillating Gradient Spin Echo Diffusion Tensor MRI of the Corpus Callosum with Typical Aging

Pascal Tétreault¹, Diana Valdés Cabrera¹, Robert Stobbe¹, Corey Baron¹, and Christian Beaulieu¹

¹Biomedical Engineering, University of Alberta, Edmonton, AB, Canada

This study compared short diffusion time (4 ms) oscillating gradient spin echo (OGSE) relative to regular long diffusion time (40 ms) pulsed gradient spin echo (PGSE) DTI in healthy individuals over a 40 year age span (n=12, 24 to 67 years old) to identify unique microstructure organization and reveal potential age related changes in three portions of the corpus callosum. Diffusivity and anisotropy were shown to depend on the diffusion time, mostly in the splenium, and these changed with age possibly reflecting alterations of restrictive dimensions such as the loss of specific axon diameters with aging.

Brain morphological alterations and functional changes during visually stimulated sexual arousal in menopausal women

Gwang-Won Kim¹, Chung-Man Moon¹, and Gwang-Woo Jeong^{1,2}

¹Research Institute of Medical Imaging, Chonnam National University Medical School, Gwangju, Korea, Republic of, ²Department of Radiology, Chonnam National University Hospital

The aging process and menopausal transition are important factors in sexual dysfunction of menopausal women. Until now, it has been unknown how menopause synchronously influences brain morphology and brain function during visually stimulated sexual arousal in menopausal women. We used structural and functional magnetic resonance imaging (fMRI) in parallel to evaluate menopause-related brain morphological and functional alterations during visually stimulated sexual arousal in menopausal women.

MR R2* and Quantitative Susceptibility Mapping: Variability in Normal Subjects across the Adult Lifespan

Christopher M O'Neill^{1,2}, Cheryl R McCreary^{1,2}, and Richard Frayne^{1,2}

¹Radiology and Clinical Neurosciences, Hotchkiss Brain Institute, University of Calgary, Calgary, AB, Canada, ²Seaman Family MR Research Centre, Foothills Medical Centre, Alberta Health Services, Calgary, AB, Canada

R2* relaxation and susceptibility measurements are both candidate biomarkers for studying brain change. The relative variability of R2* and quantitative susceptibility mapping (QSM) approaches was studied in six deep brain regions in 182 normal subjects (18-89 years). The variability of R2* measures (average coefficient of variation, CoV: 0.33, mean \pm standard deviation over regions) was found to be significantly less than QSM measurements (average CoV: 5.72). The variability in R2* measurements was found to vary with age, unlike QSM which showed no age effects. The increased variability observed in QSM measurements, however, may obscure smaller age effects.

Computer 103

The Effects of Long-Term Physical Intervention for Active Ageing on the White Matter Hyperintensities in Older Adults

Toshiharu Nakai^{1,2}, Noriko Ogama³, Takashi Sakurai⁴, Mika Ueno¹, Sachiko Kiyama^{1,5}, and Ayuko Tanaka^{1,6}

¹NeuroImaging & Informatics, National Center for Geriatrics & Gerontology, Ohbu, Japan, ²Department of Radiological Science, Nagoya University Graduate School of Medicine, Nagoya, Japan, ³Center for Comprehensive Care and Research on Memory Disorders, National Center for Geriatrics and Gerontology, Ohbu, Japan, ⁴Center for Comprehensive Care and Research on Memory Disorders, National Center for Geriatrics & Gerontology, Ohbu, Japan, ⁵College of Liberal Arts and Sciences, Mie University, Tsu, Japan, ⁶Faculty of Human Sciences, Kobe Shoin Women's University, Kobe, Japan

The relationship between the history of participation in community based physical exercise activity and the volume of white matter hyperintensity was evaluated in order to investigate the long-term effects of physical exercises on the neurophysiological status of brain to support cognitive processing in older adults. The FLAIR MR images obtained from 54 community dwelling older adults were segmented semi-automatically and the WMH volumes were quantified. It was suggested that long-term physical exercises more than 5 years for 90 minutes once per week may potentially reduce the progress of WMH lesions as well as the risk of fall.

4263

Computer 104

QSM and R2* texture analysis in the aging brain

Arturo Cardenas-Blanco^{1,2}, Matthew J Betts¹, Peter J Nestor¹, Emrah Düzel^{1,2}, and Julio Acosta-Cabrero¹

¹DZNE, Magdeburg, Germany, ²Institute of cognitive neurology and dementia research (IKND), Magdeburg, Germany

To date, several studies have shown the value of quantitative susceptibility mapping (QSM) and R2* to detect aging-associated neurobiological mechanisms often based on single parametric features, either mean or median values, to characterise QSM/R2* behaviours in regions of interest (ROIs). In this study we propose the use of Haralick texture features to probe regional distribution characteristics of voxel intensities in R2*/QSM images. The results demonstrate that Haralick texture features add value to study the aging brain since they increase significantly the accuracy in subcortical R2*/QSM differentiation between elderly and young subjects.

Computer 105

Changes in myelination and cortical thickness with advancing age

Andrew John Carradus¹, Benjamin Hunt¹, Prejaas Tewarie¹, Nicolas Geades¹, Simon Shah¹, Olivier Mougini¹, Matthew Brookes¹, and Penny Gowland¹

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom

This study explores the relationships that cortical myelination and cortical thickness have with age, and expands on existing literature by investigating whether the previously reported trends are still present when only looking at individual lobes of the brain. We find that quadratic variations occur in all four lobes of the brain in regards to myelination, and that cortical thickness declines linearly with age in all lobes except the temporal. We also find that myelination levels and cortical thickness appear to change independently of each other.

4265

Computer 106

Cross-Sectional Assessment of Diffusion Parameters in Specific Brain Tracts correlated with Cortical Thinning throughout Healthy Aging

Maira Siqueira Pinto¹, Antônio Carlos dos Santos², and Carlos Ernesto Garrido Salmon¹

¹InBrain Lab, Department of Physics, Faculty of Philosophy, Sciences and Letters of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, ²Department of Internal Medicine, Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil

The human brain is a complex structure that undergoes continuous, non-linear changes over the lifespan. We used anatomic and diffusion data from 165 healthy subjects, collected retrospectively from CCIFM/HC-FMRP. T1-weighted images were used for cortical parcellation, thus 102 of 148 cortical regions had statistically significant decrease with age. Three fiber tracts were selected: Corpus Callosum, Uncinate Fasciculus and Corticospinal Tract, their diffusion parameters, FA and MD, showed significant relationship with cortical thickness of the biggest cortical area in the ending of each tract. Despite these correlations, it was possible to verify that age is the pivotal variable in this relationship.

4266

Computer 107

Human Connectome Project (HCP) Lifespan Pilot: age-course of structural, microstructural and functional parameters in the hubs of the default mode network

Daniele Mascali¹, Emily Kittelson², Keith Jamison², Kâmil Uğurbil², Essa Yacoub², Shalom Michaeli², Lynn Eberly³, Melissa Terpstra², Federico Giove¹, and Silvia Mangia²

¹Museo Storico della Fisica e Centro Studi e Ricerche "Enrico Fermi", Rome, Italy, ²Center for Magnetic Resonance Research, Dept. of Radiology, University of Minnesota, Minneapolis, MN, United States, ³Division of Biostatistics, University of Minnesota, Minneapolis, MN, United States

Age-courses of multiple MRI outcomes were here characterized with a specific focus to default mode network (DMN) regions. Data were collected with unprecedented sensitivity and spatial resolution using the Human Connectome Project Lifespan Pilot protocol from 65 subjects divided in 4 age-groups (teen, young, middle-age and older adults). Age-related decreases of grey matter volumes, mean diffusivity, amplitude of resting-state oscillations and regional homogeneity were observed in both anterior and posterior DMN, and were more pronounced in anterior than in posterior DMN. Connectivity between posterior and anterior DMN regions remained relatively stable during the lifespan.

4267

Computer 108

Investigating the compensatory mechanisms of the ageing brain in response to a sub-maximal exercise task

Andrew Hale^{1,2}, Penny Gowland¹, Paul Greenhaff^{1,2}, and Susan Francis¹

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom, ²MRC/ARUK Centre for Musculoskeletal Ageing Research, University of Nottingham, Nottingham, United Kingdom

Age-related alterations in cerebral vascular function may be better understood by investigating cerebral response to exercise. We performed a MR study involving low/moderate intensity exercise in healthy young and older subjects. We assess the effect of exercise on CBF response, cerebral oxygenation, and CMRO₂. We also investigate the relationship of GM-volume and physical fitness with ageing. At rest, there was no difference between CBF and CMRO₂ but an increase in oxygen extraction with age. On exercise the age-related increase in OEF remained, however CBF and CMRO₂ were blunted in older subjects. GM-volume was found to be associated with VO_{2max}.

4268

Computer 109

A two-region approach to assess brain iron changes as a function of age in basal ganglia, midbrain and dentate nuclei of healthy subjects using quantitative susceptibility mapping

Kiarash Ghassaban¹, Sean K Sethi¹, Shuang Xia², and E. Mark Haacke^{1,3}

¹Magnetic Resonance Innovations Inc., Detroit, MI, United States, ²Department of Radiology, Tianjin First Central Hospital, Tianjin, People's Republic of China, ³Department of Radiology, Wayne State University, Detroit, MI, United States

In this work, 81 healthy subjects were recruited to assess iron deposition as a function of age in eight major brain nuclei using quantitative susceptibility mapping. By thresholding out high iron content region for each structure, seven basal ganglia and midbrain structures were evaluated locally and compared with the literature. Global (the entire structure) and regional (high iron content) susceptibility changes versus age were also analyzed for the dentate nucleus. In addition to the global analysis being consistent with the literature, regional analysis showed more sensitivity and precision as well as the left hemisphere dominance in terms of iron deposition.

Computer 110

High Resolution Magnetic Resonance Histology of the Human Brain Temporal Lobe

Alexandra Badea¹, Nian Wang¹, Gary P Cofer¹, Simon W Davis², John F Ervin², Dianne A Cruz³, and G Allan Johnson¹

¹Center for In Vivo Microscopy, Department of Radiology, Duke University Medical Center, Durham, NC, United States, ²Department of Neurology, Duke University Medical Center, Durham, NC, United States, ³Departments Psychiatry and Behavioral Science, Duke University Medical Center, Durham, NC, United States

Detecting early brain changes in neurodegenerative diseases such as Alzheimer's disease (AD) is essential for enabling interventions. We thus need to increase our ability to accurately localize areas that change, and to quantifying changes. The temporal lobe is essential for memory function. This is where AD hallmarks such as plaques, tangles, and neuronal death happen first. White matter has been proposed to have a role in early AD. We use high resolution magnetic resonance histology and diffusion tensor imaging to characterize the temporal lobe and its tracts. A compressed sensing acquisition with cluster based reconstruction increased efficiency four-fold.

Effects of Working Memory Training on Microstructural Brain Changes in HIV-positive and Seronegative Subjects

Chad Otoshi¹, Thomas Ernst¹, Kenichi Oishi², Hua Jun Liang¹, David Greenstein¹, and Linda Chang¹

¹Department of Medicine, University of Hawaii John A. Burns School of Medicine, Honolulu, HI, United States, ²Department of Radiology and Radiological Science, Johns Hopkins Medicine, Baltimore, MD, United States

Microstructural brain changes before, 1-month and 6-months and after working Memory Training was evaluated in both HIV-positive and seronegative individuals. While working memory training improved performance in both trained and non-trained working memory tasks, brain diffusivities increased in most brain regions after training in both groups, more in HIV than controls in some regions. These findings suggest ongoing brain inflammation associated with normal aging or HIV may mask the training-related changes in DTI measures.

4271

Computer 112

Aging effects on kurtosis measures of limbic and association white matter tracts

Qinmu Peng^{1,2}, King Kevin^{3,4}, Minhui Ouyang¹, Hanzhang Lu⁵, and Hao Huang^{1,2}

¹Department of Radiology, Children's Hospital of Philadelphia, Philadelphia, PA, United States, ²Department of Radiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States, ³Department of Imaging, Huntington Medical Research Institutes, ⁴Department of Radiology, University of Texas Southwestern Medical Center, ⁵Department of Radiology, Johns Hopkins University

Numerous studies have revealed that DTI-derived metrics are sensitive to the microstructural changes of the aging white matter tracts. However, microstructural changes associated with non-Gaussian water diffusion cannot be quantified by DTI-derived metrics, but uniquely quantified by DKI-derived metrics. Little is known on the progressive white matter microstructural changes measured by DKI-derived metric during aging. In this study, we found that the measurements of DKI-derived mean kurtosis (MK) decrease heterogeneously across white matter tracts, characterized with significant MK decreases in limbic tracts including fornix and cingulum and insignificant MK decreases in the association tracts.

Here we study normal brain aging in wild type C57BL/6 mice and have detected a decline in cerebrovasculature over the two year aging process

4273 Computer 114 Age Related Differences in the geomT2 Relaxation Assessed Using Multi-Echo T2 Imaging

Muzamil Arshad^{1,2}, Jeffrey A. Stanley¹, and Naftali Raz^{3,4}

¹Psychiatry and Behavioral Neurosciences, Wayne State University School of Medicine, Detroit, MI, United States, ²MD/PhD Program, Wayne State University School of Medicine, Detroit, MI, United States, ³Psychology, Wayne State University, ⁴Institute of Gerontology, Wayne State University

Multi-echo T₂ imaging (ME-T₂) enables the investigation of multiple white matter compartments. The short T₂ compartment has been the focus of recent investigations due to its specificity for the myelin water compartment. However, the much larger intra/extracellular (IE) compartment has been relatively less explored. Here we investigate age differences in the geometric mean T₂ (geomT_{2IEW}) of the IE compartment in subcortical white matter tracts. We demonstrate that the effects of age on geomT_{2IEW} are not uniform across white matter tracts and suggest that this index may offer additional value in the characterization of age differences of white matter microstructure.

4274 Computer 115 Quantification of Brain Metabolites in Alcohol Dependent Patients Using MRS with Experimental Basis Sets at 3T

Hyeon-Man Baek^{1,2} and Yeong-Jae Jeon^{1,2}

¹Korea Basic Science Institute, Ochang, Korea, Republic of, ²Dept. Bio-Analytical Science, Univ of Science & Technology, Daejeon, Korea, Republic of

In this study, in vivo quantification of brain metabolites measured on the dorsolateral prefrontal cortex (DLPFC) was carried out with LCModel using a priori knowledge based on experiment metabolite basis set signals. The main observation in this work was the significant reduction of tCho and Ins, and increase of GSH and Glx concentrations in the left DLPFC of alcohol dependent patients compared to healthy control subjects.

4275 Computer 116 Anomalous diffusion γ metrics detects physiological and microstructural changes in brain normal aging

Michele Guerrieri^{1,2}, Alessandra Caporale^{1,3}, Marco Palombo⁴, Emiliano Macaluso⁵, Marco Bozzali⁶, and Silvia Capuani¹

¹CNR ISC UOS Sapienza University of Rome, Rome, Italy, ²SAIMLAL Dept., Morphogenesis and Tissue Engineering, Sapienza University of Rome, Rome, Italy, ³SAIMLAL Dept., Morphofunctional Sciences, Sapienza University of Rome, ⁴MIRcen, CEA/DSV/I2BM, Fontenay-Aux Roses, France, ⁵ImpAct Team, Lyon Neuroscience Research Center, Lyon, France, ⁶Neuroimaging Laboratory, Santa Lucia Foundation, Rome, Italy

The intent of this study was to test the potential of parameters extracted by the so-called anomalous diffusion (AD) stretched exponential γ -imaging model, to detect microstructural modifications occurring in brain during normal aging. Conventional DTI metrics was also considered. 27 healthy volunteers with age range 21-77y underwent DW acquisitions. Parametric maps of Mean γ (My) and γ Anisotropy (γA) were obtained and a quantitative analysis was carried in different regions of White and Deep Grey Matter. We found that AD and DTI parameters correlations with age indicate changes in different brain regions diversifying thus aging patterns.

4276 Computer 117 Sub-clinical trait anxiety relates to cerebral blood flow in brain regions related to autonomic arousal

William J Cottam^{1,2,3}, Diane Reckziegel^{1,2,3}, Marianne M Drabek^{1,2,3}, and Dorothee P Auer^{1,2,3}

¹Radiological Sciences, Division of Clinical Neuroscience, University of Nottingham, Nottingham, United Kingdom, ²Arthritis Research UK Pain Centre, University of Nottingham, Nottingham, United Kingdom, ³Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom

Arterial spin labelling is a powerful, non-invasive tool to map cerebral blood flow (CBF) in the study of neural activity patterns underpinning spontaneous behaviour or personality traits. In this study we sought to directly investigate the effects of negative affect, specifically trait anxiety on local cerebral blood flow in a group of patients with chronic pain known to have mildly elevated anxiety scores. This study found widespread cerebral blood flow in osteoarthritis subjects with chronic pain that correlate significantly with trait anxiety, overlapping with regions previously reported to relate to autonomic functions. fMRI studies should account for increased physiological arousal.

4277 Computer 118 Evaluation of aging effects on cerebral hemodynamics by Magnetic Resonance Imaging

João Paulo Santos Silva¹, Ícaro Agenor Oliveira¹, André Monteiro Paschoal¹, and Renata Ferranti Leoni¹

¹Physics, University of Sao Paulo, Ribeirao Preto, Brazil

Recently, the effects of aging on human brain tissue, mainly how structural changes may be related to functional changes, have been extensively discussed. However, there is still no agreement on which brain regions have altered perfusion and how it is related with dementia. Therefore, in the present study, we investigated regional changes in perfusion and gray matter concentration in healthy aging, Mild Cognitive Impairment and Alzheimer's disease. The results indicate a significant age- and disease-related reduction of regional cerebral perfusion associated with brain atrophy. Therefore, these alterations may be important biomarkers for neurodegeneration.

4278 Computer 119 Both Rostral and Dorsal Anterior Cingulate Cortices Exhibit Age-related Metabolic Changes

Pui Wai Chiu^{1,2}, Hui Zhang¹, Savio Wai Ho Wong³, Tianyin Liu⁴, Gloria Hoi Yan Wong⁵, Queenie Chan⁶, and Henry Ka Fung Mak^{1,2,7}

Computer 120

Memory Recall Accuracy is Associated with Glutamatergic Neurotransmission in the Right Hippocampus

Pui Wai Chiu^{1,2}, Hui Zhang¹, Savio Wai Ho Wong³, Tianyin Liu⁴, Gloria Hoi Yan Wong⁵, Queenie Chan⁶, and Henry Ka Fung Mak^{1,2,7}

¹Department of Diagnostic Radiology, The University of Hong Kong, Hong Kong, Hong Kong, ²State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, Hong Kong, ³Department of Special Education and Counselling, The Education University of Hong Kong, Hong Kong, Hong Kong, Hong Kong, ⁴Sau Po Centre on Ageing, The University of Hong Kong, Hong Kong, Hong Kong, ⁵Department of Social Work and Administration, The University of Hong Kong, Hong Kong, Hong Kong, ⁶Philips Healthcare, Hong Kong, Hong Kong, Hong Kong, ⁷Alzheimer's Disease Research Network, The University of Hong Kong, Hong Kong, Hong Kong, Hong Kong

Memory for face-name associations is an important type of memory in our daily lives, and often declines in older adults, but the neural mechanisms underlying such decline are still unknown. In this study, quantitative proton magnetic resonance spectroscopy was used to investigate the metabolic changes in the bilateral hippocampi in a local Chinese cohort at 3.0T. The relationship between metabolite concentrations and memory recall accuracy from a face-name recognition task was also assessed. Right hippocampus revealed the plausibility of compensation activity during aging, and the memory recall accuracy was associated with alterations in glutamatergic neurotransmission.

Visualizing the role of ideal current patterns in minimizing sample noise using dark mode current patterns for a spherical sample

Manushka V. Vaidya^{1,2,3}, Daniel K. Sodickson^{1,2,3}, Christopher M. Collins^{1,2,3}, and Riccardo Lattanzi^{1,2,3}

¹Center for Advanced Imaging Innovation and Research (CAI2R), Department of Radiology, New York University School of Medicine, New York, NY, United States, ²Bernard and Irene Schwartz Center for Biomedical Imaging, Department of Radiology, New York University School of Medicine, New York, NY, United States, ³Sackler Institute of Graduate Biomedical Sciences, New York University School of Medicine, New York, NY, United States

We show that the ideal surface current patterns maximizing internal signal-to-noise ratio (SNR) are composed of a) signal-optimizing current patterns which maximize the signal sensitivity without considering sample noise, and b) "dark mode" current patterns which minimize sample noise without affecting signal. For a central voxel in a spherical sample, the absence of dark mode current patterns on an encircling sphere suggests that optimally tracking the precessing spin while ignoring sample noise is sufficient to achieve the best possible SNR. For an off-center voxel, however, the dark mode current patterns form high magnitude localized currents that efficiently minimize sample noise.

Computer 98

The Twisted Solenoid RF Phase Gradient Transmit Coil for TRASE Imaging

Stephanie Yong¹, Boguslaw Tomanek², and Jonathan C. Sharp²

¹Physics, University of Alberta, Edmonton, AB, Canada, ²Oncology, University of Alberta, Edmonton, AB, Canada

TRASE is a k-space encoding method that uses RF transmit phase gradient fields to achieve mm-level resolution. However, image quality is critically dependent upon the efficient generation of B_1 fields with uniform magnitude and strong phase gradients. We present a new family of phase gradient coil designs based upon a solenoid twisted about a transverse axis. Four twisted solenoids wound on a single cylindrical former are sufficient to encode two spatial dimensions. The design has many attractive geometric, electrical and magnetic characteristics, including the ability to encode in the B_0 -direction, previously not possible for transverse- B_0 magnet geometries.

4282

Computer 99

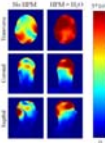

Alternative approach for modeling a geometrically complex RF coil for evaluation in simulation.

Gillian G Haemer^{1,2,3}, Nicole Wake^{1,2,3}, Martijn Cloos^{1,2}, Christopher Collins^{1,2,3}, Daniel K Sodickson^{1,2,3}, and Graham C Wiggins^{1,2}

¹The Center for Advanced Imaging Innovation and Research (CAI2R), Department of Radiology, New York University School of Medicine, New York, NY, United States, ²The Bernard and Irene Schwartz Center for Biomedical Imaging, Department of Radiology, New York University School of Medicine, New York, NY, United States, ³The Sackler Institute of Graduate Biomedical Sciences, New York University School of Medicine, New York, NY, United States

An alternative approach for generating a digital model of an RF coil is described that avoids the use of geometric priors and ensures structural accuracy. This approach is demonstrated on a helmet-shaped transmit-receive coil, and the resulting simulations are compared to experimental data.

- 4283 **Computer 100** [Evaluation of a high permittivity helmet for use as a coil former for an 8ch transmit/receive array with dodecahedral symmetry.](#)
 Gillian G Haemer^{1,2,3}, Manushka V Vaidya^{1,2,3}, Christopher Collins^{1,2,3}, Daniel K Sodickson^{1,2,3}, and Graham C Wiggins^{1,2}

¹The Center for Advanced Imaging Innovation and Research (CAI2R), Department of Radiology, New York University School of Medicine, New York, NY, United States, ²The Bernard and Irene Schwartz Center for Biomedical Imaging, Department of Radiology, New York University School of Medicine, New York, NY, United States, ³The Sackler Institute of Graduate Biomedical Sciences, New York University School of Medicine, New York, NY, United States
 A helmet shaped coil former made of high permittivity material is simulated with an 8 channel transmit/receive coil as an evaluation step towards coil construction. The addition of the high permittivity material improves performance in both transmit and receive but the choice of a permittivity that is too high may lead to undesired split-resonance effects.

 Anh Tran¹, Sergey Makarov^{1,2}, and Harshal Tankaria

¹Worcester Polytechnic Institute, Worcester, MA, United States, ²NEVA Electromagnetics, LLC, Yarmouth Port, MA, United States
 Respiratory motion is an important problem in Magnetic Resonance Imaging (MRI), contributing to image blurring during data acquisition and coil detuning. Using the concept of an ideal (perfectly matched and tuned at all available ports) RF transmit coil and the VHP-Female v4.0 dynamic CAD model, we estimate the detuning of a full-body RF coil during the respiratory cycle. Our results show that the computed resonant capacitance values change by at most 0.5%.
-
- 4289 **Computer 106** [Design of Elliptical Birdcage Coil with Constant Ring-capacitor Value](#)

Yoshihisa Soutome¹, Shin-ichiro Suzuki², Hideta Habara², Takahide Shimoda², and Yoshitaka Bito²

¹R&D Group, Hitachi, Ltd., Kokubunji, Japan, ²Healthcare Business Unit, Hitachi, Ltd., Tokyo, Japan

The value of ring capacitors in elliptical birdcage coil (EBC) should be varied gradually according to the location of the ring capacitor in order to generate uniform B_1^+ field distribution. Usually, it is difficult to adjust the value of the ring capacitor precisely by using fixed capacitors, because the value of the fixed capacitor is discretized. To realize the easy fabrication of EBC, we have designed EBC with constant ring-capacitor value at 1.5T. Simulation and experimental results indicated that the designed EBC generated uniform B_1^+ field distribution and showed the same transmission efficiency as the conventional EBC.

Computer 107

Ultra-high field RF coils with adjustable longitudinal coverage: Traveling-wave meets standing-wave
Xinqiang Yan^{1,2}, John C. Gore^{1,2,3}, and William A. Grissom^{1,2,3}

¹Institute of Imaging Science, Vanderbilt University, Nashville, TN, United States, ²Department of Radiology and Radiological Sciences, Vanderbilt University, Nashville, TN, United States, ³Department of Biomedical Engineering, Vanderbilt University, Nashville, TN, United States

7T scanners currently are not equipped with body coils, so for MR imaging of relatively short coverage along the z-direction (head, knee and prostate), local transmit coils with standing-wave behavior are commonly used to achieve high efficiency. For MR imaging that requires long coverage such as the legs, traveling wave MRI is potentially a competitive choice since it is extremely simple to implement and enables large FOV imaging. In this study, we propose a coverage-adjustable transmit coil which combines the concepts of traveling-wave and standing-wave. The new design exhibits excellent efficiency over short regions, but maintains the ability to cover longer areas for MR imaging of the legs or whole body.

4291

Computer 108

Improved traveling wave efficiency in 7T human MRI using wireless local loop and dipole arrays
Xinqiang Yan^{1,2}, Xiaoliang Zhang^{3,4}, John C. Gore^{1,2,5}, and William A. Grissom^{1,2,5}

¹Institute of Imaging Science, Vanderbilt University, Nashville, TN, United States, ²Department of Radiology and Radiological Sciences, Vanderbilt University, Nashville, TN, United States, ³Department of Radiology and Biomedical Imaging, University of California San Francisco, San Francisco, CA, United States, ⁴UCSF/UC Berkeley Joint Graduate Group in Bioengineering, San Francisco, CA, United States, ⁵Department of Biomedical Engineering, Vanderbilt University, Nashville, TN, United States

Traveling-wave MRI has robust matching performance and capability for large field-of-view (FOV) imaging. However, the efficiency of traveling-wave MRI is much lower than conventional methods, which limits its application. One way to improve the efficiency is to place local wireless resonators around the subject. The feasibility of this approach has been demonstrated in previous works using a single small loop. However, it is not clear whether other kinds of coils (such as electric dipoles) can be used as local elements, and it is not clear how much the improvements can be maintained in human imaging using an array design. By using wireless local loop coil and transverse dipole arrays, the transmit efficiency (B_1^+) of traveling-wave MRI can be improved by 3.4-fold in the brain and 2-fold in the knee. The coil types (loops or dipoles) should be carefully chosen for brain or knee imaging to maximize the improvement since they exhibit different types of coupling to the TE_{11} mode, and the enhancement depends on the local body configuration

New resonator geometries for ICE decoupling of loop arrays
Xinqiang Yan^{1,2}, John C. Gore^{1,2,3}, and William A. Grissom^{1,2,3}

¹Institute of Imaging Science, Vanderbilt University, Nashville, TN, United States, ²Department of Radiology and Radiological Sciences, Vanderbilt University, Nashville, TN, United States, ³Department of Biomedical Engineering, Vanderbilt University, Nashville, TN, United States

To overcome B_1 inhomogeneities and technological difficulties in building large-sized volume resonators, multi-channel arrays are commonly used for transmission at ultra-high fields. One of the main challenges in designing transmit arrays is to minimize the coupling among coil elements. The induced current elimination (ICE) method, which uses additional resonator elements to cancel coils' mutual electromagnetic (EM) coupling, has proven to be a simple and efficient approach to decouple loop, stripline and dipole arrays. However, in previous embodiments the decoupling elements acted as "magnetic-walls", blocking the magnetic field and leading to MR signal loss near the elements. In this study, we improved the ICE method to avoid the signal cancellation by using overlapped and perpendicular decoupling loops.

Computer 110

An analytic expression for the ultimate intrinsic SNR in a uniform sphere
Hong-Hsi Lee¹, Daniel K. Sodickson¹, and Riccardo Lattanzi¹

¹Center for Biomedical Imaging, New York University, New York, NY, United States

Ultimate intrinsic SNR (UISNR) is the theoretically highest SNR for given geometry and electrical properties, independent of the coil design. Here, we introduce an analytic exact expression to calculate the UISNR at the sphere center, enabling to directly analyze the dependence on main magnetic field, sample geometry and electric properties. The analytic expression can approximate the UISNR near the center with < 5% error. This work can enable people without access to the full simulation code to calculate UISNR and use it, for example, as an absolute reference to assess the performance of head coils with spherical phantoms.

Computer 111

A Novel Optimization Method for the Design of Permanent Magnet Array and its Application to a Portable Magnetic Resonance Imaging (MRI) System

Zhi Hua Ren¹ and Shao Ying Huang^{1,2}

¹EPD, Singapore University of Technology and Design, Singapore, Singapore, ²Department of Surgery, National University of Singapore, Singapore, Singapore

Permanent magnet array is a welcome option to provide main magnetic field for portable magnetic resonance imaging (MRI). In this abstract, we propose an efficient and fast optimization method which can optimize the field strength and homogeneity for the design of permanent magnet arrays. The magnetic field of permanent magnets with the interference of irons is calculated by applying boundary integral method (BIM). For optimization, genetic algorithm particle swarm optimization (GAPSO) is applied which offers highly diversified options and converges fast. A permanent magnet array is optimized with significantly improved performance, and it will be built for low-field portable MR imaging.

4295

Computer 112 Decoupling and Integration of Electric Dipoles into RF Arrays

Ian Robert Oliphant Connell^{1,2} and Ravi S Menon^{1,2}

¹Centre for Functional and Metabolic Mapping, Robarts Research Institute, London, ON, Canada, ²Medical Biophysics, University of Western Ontario, London, ON, Canada

To-date, increasing interest in adapting dipole antennae for imaging at ultra-high field strengths has spawned the design and construction of many dipole-based RF arrays. However, increased electric-field interactions between dipole-to-sample and dipole-to-dipole provide an implementation barrier due to mutual coupling and load-sensitivity. This study presents an analysis of dipole-to-dipole coupling and implements a filter design method to isolate dipole elements in a highly-conformal array designed for human brain imaging at 7 Tesla.

4296

Computer 113 RF Pulse Design - based Parallel Transmit Array Design

Zhipeng Cao^{1,2}, Xinqiang Yan², Jun Ma^{1,2}, and William A. Grissom^{1,2}

¹Biomedical Engineering, Vanderbilt University, Nashville, TN, United States, ²Institute of Imaging Science, Vanderbilt University, Nashville, TN, United States

A novel parallel transmit array design method is proposed that integrates both Maxwell and Bloch equations. The method is demonstrated to be better than traditional coils in dynamic multiband shimming and reduced field-of-view imaging scenarios to achieve better excitation accuracy and lower RF energy deposition, as well as robustness across multiple subjects and excitation schemes.

4297

Computer 114 Wireless Q-spoiling of Receive Coils at 1.5T MRI

Jonathan Y Lu¹, Fraser Robb², John Pauly¹, and Greig Scott¹

¹Electrical Engineering, Stanford University, Stanford, CA, United States, ²Advanced Coils, GE Healthcare Inc, Aurora, OH, United States

In this work, we demonstrate wireless Q-spoiling of an MRI surface coil in a 1.5T scan using commercial Linx LR series modules. These modules send a digital data stream wirelessly using an On-Off-Keying (OOK) protocol and a carrier frequency of 418MHz. With the simple Linx modules for wireless scanner state detection, it becomes possible to perform tasks such as wirelessly Q-spoiling MRI receive coils and beginning readout of receive coil data. Such steps are necessary for the ultimate goal of wireless MRI.

4298

Computer 115 A Simple Setup to Measure the Noise Figure of MRI Preamplifiers

Roland Müller¹ and Harald E. Möller¹

¹Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany

Noise figure measurements have the reputation of being intricate and needing special equipment. Here, we will demonstrate that a simple setup involving an RTL-SDR dongle achieves convenient results. It requires, besides the inexpensive dongle, only common equipment, which should be available in all MRI coil labs.

4299

Computer 116 Practical aspects of preamplifier designs for ¹³C imaging.

Daniel Højrup Johansen¹, Juan D. Sanchez-Heredia¹, Vitaliy Zhurbenko¹, and Jan H. Ardenkjær-Larsen¹

¹Department of Electrical Engineering, Technical University of Denmark, Kgs. Lyngby, Denmark

This abstract presents two preamplifier designs for ¹³C imaging optimized either for single or array coil usage. For single coil usage the preamplifier is designed to minimize noise yielding a noise figure of 0.25 dB. For array coils coupling between elements is a problem when the input impedance of the preamplifier is high. Hence the main contribution of this work is a low resistance, inductive input impedance preamplifier yielding better decoupling for array coils, while maintaining acceptable gain (20 dB) and noise figure (0.75 dB).

4300

Computer 117 Comparison of different RF coil designs for short T₂* samples

Agazi Samuel Tesfai¹, Johannes Fischer¹, Ali Caglar Özen¹, and Michael Bock¹

¹Dept. of Radiology, Medical Physics, Medical Center – University of Freiburg, Freiburg, Germany

MRI of short T₂* samples is possible with ultra-short echo time sequences (UTE) which can be further improved using dedicated RF coils optimized for short-TE imaging. This work compares the performance of a commercial wrist coil with two custom-built coils (birdcage, solenoid) for UTE imaging of a mummy hand (low water content, short T₂*), and an *in-vivo* measurement of a human hand in which short-T₂* tissues such as tendons are highlighted by UTE image subtraction.

4301

Computer 118 Effect of Mismatching on the Transmit and Receive Performance of a Human Head 9.4T Tight-Fit Transceiver Phased Array.

Nikolai I. Avdievich¹, Ioannis A. Giapitzakis¹, and Anke Henning^{1,2}

¹Max Planck Institute for Biological Cybernetics, Tübingen, Germany, ²Institute of Physics, Ernst-Moritz-Arndt University, Greifswald, Germany

Tight-fit multi-channel ultra-high field (UHF, ≥ 7 T) transceiver (TxRx) phased arrays improve transmit (Tx) efficiency in comparison to larger Tx-only arrays. However, tight-fit TxRx-arrays may require matching for each subject. To evaluate a potential use of tight-fit TxRx-arrays without matching, we investigated both numerically and experimentally an effect of a strong mismatch on performance of a 9.4T 8-channel human head TxRx-array. We demonstrated that mismatching caused only ~5% decrease of the B_1^+ field, while may have stronger effect on the maximum local SAR. Additionally it also effects the SNR distribution. While overmatching favors SNR, undermatching may enhance Tx-efficiency evaluated as $B_1^+ \sqrt{\text{SAR}_{10g}}$.

4302

Computer 119

ANALYTICAL RF COILS DECOUPLING: A THEORETICAL APPROACH FOR PARALLEL TRANSMISSION

Angelo Galante^{1,2,3}, Marco Fantasia¹, Piero Sebastiani⁴, Antonello Sotgiu⁴, and Marcello Alecci^{1,2,3}

¹Department of Life, Health and Environmental Sciences, L'Aquila University, L'Aquila, Italy, ²Laboratori Nazionali del Gran Sasso, Istituto Nazionale di Fisica Nucleare, L'Aquila, Italy, ³Istituto SPIN-CNR, CNR, L'Aquila, Italy, ⁴Imaging Technology Abruzzo, L'Aquila, Italy

We show, by Finite Elements Modelling, the tuning and matching feasibility of a highly coupled parallel transmission (PTx) array by means of two degrees of freedom (two capacitances values) and decouple them a posteriori. This approach could be useful to simplify the design of PTx arrays avoiding complex procedures to geometrically and/or electrically decouple the elements. The procedure is stable for small parameters changes and this suggests a possible experimental verification of the results.

Experimental realization of a novel dual-nuclei coil for small animal imaging at 7 Tesla based on periodic structures of metal strips

Anna A. Hurshkainen¹, Anton V. Nikulin¹, Stanislav B. Glybovski¹, Irina V. Melchakova¹, Pavel A. Belov¹, Benoit Larrat², Elodie Georget², Stefan Enoch³, Pierre Sabouroux³, Ana L. Neves³, and Redha Abdeddaim³

¹Department of Nanophotonics and Metamaterials, ITMO University, Saint-Petersburg, Russian Federation, ²DRF/I2BM/Neurospin/UNIRS, CEA-Saclay, Paris, France, ³CNRS, Institut Fresnel, Aix-Marseille Université, Marseille Cedex, France

In order to acquire image or MR spectra at two different nuclei dual-frequency RF-coils are used. Conventional approaches of tuning and matching a coils at several frequencies employ expensive non-magnetic capacitors which also introduce dissipative losses. We propose an alternative method of tuning and matching the coils at multiple desired frequencies. This method is based on resonant excitation of hybridized eigenmodes of periodic structures of metal strips. The proposed method allows one to build cheap coil with reduced dissipative losses resonating on two different frequencies simultaneously.

32-Channel In-Vivo Parallel Transmit Body Imaging at 7 Tesla

Sören Johst¹, Sascha Brunheim^{1,2}, Marcel Gratz^{1,2}, Harald H Quick^{1,2}, Mark E Ladd^{1,3}, and Stephan Orzada¹

¹Erwin L. Hahn Institute for MRI, University Duisburg-Essen, Essen, Germany, ²High Field and Hybrid MR Imaging, University Hospital Essen, Essen, Germany, ³Division of Medical Physics in Radiology (E020), German Cancer Research Center (DKFZ), Heidelberg, Germany

In this work we present phantom and in-vivo pTx excitation results acquired with a 32-channel add-on pTx system based on a 1-channel 7T MRI system. The add-on system uses custom-built I/Q modulators and custom-built amplifiers located inside the magnet room. The single exciter channel is split into 32 sub-channels, whereby the modulators control the phase and amplitude of the individual pTx RF pulses. The modulators and pre-calculated pTx gradients are synchronized via trigger signals generated in the imaging sequence. With the 32-channel pTx system, reduced FOV imaging of the lumbar vertebrae during free breathing was possible.

4305

Computer 51

A 8-channel pTx transceive coil for hip imaging at 7 T

Jin Jin¹, Ewald Weber¹, Kieran O'Brien², Aurelien Destruel¹, Bassem Henin³, Craig Engstrom¹, and Stuart Crozier¹

¹University of Queensland, St Lucia, Australia, ²Siemens Ltd, Brisbane, Australia, ³American University of the Middle East, Kuwait

This paper presents the initial in vivo imaging results from a new unilateral 8-channel pTx transceive array designed and constructed for 7 T MRI of the hip joint. With subject-specific RF shims, 3D sequences (DESS and MEDIC) provided sufficient coverage, uniform image intensity and excellent contrast. The RF techniques employed in the construction of the array promote efficient use of RF power, enabling turbo spin echo sequences with full coverage of hip joint to be performed with adequate excitation. Comprehensive and conservative RF safety procedures ensure that local RF energy absorption is well below regulatory limits.

4306

Computer 52

Comparison of a 32-channel remote body coil for 7 Tesla with local and remote 8- and 16-channel transmit coil arrays

Thomas M. Fiedler¹, Martina Flöser¹, Stefan H. G. Rietsch^{2,3}, Stephan Orzada², Harald H. Quick^{2,3}, Mark E. Ladd^{1,2}, and Andreas K. Bitz¹

¹Medical Physics in Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany, ²Erwin L. Hahn Institute for MRI, University Duisburg-Essen, Essen, Germany, ³High Field and Hybrid MR Imaging, University Hospital Essen, Essen, Germany

The RF shimming performance of a 32-channel remote body coil is compared to ideally and non-ideally decoupled local and remote arrays consisting of 8 and 16 channels by evaluation of the singular values as well as evaluation of the RF shimming performance in axial and coronal slices with L-curves. For high-field body imaging, multi-ring remote coil arrays provide high degrees of freedom for RF shimming and can achieve higher B1+ homogeneity, especially for coronal slices. However, to utilize the full RF shimming potential of remote multi-ring transmit arrays, high local SAR has to be taken into account during safety assessment.

4307

Computer 53

Occipital-parietal coil with variable-density element distribution for 7T functional imaging

Kyle M Gilbert¹, Joseph S Gati¹, and Ravi S Menon¹

¹Centre for Functional and Metabolic Mapping, The University of Western Ontario, London, ON, Canada

A 32-channel receive coil with variable-density element distribution, in conjunction with an 8-channel transmit coil, was developed for imaging of the occipital-parietal regions of human brain at 7T. Spatial SNR maps demonstrate targeted sensitivity to the peripheral occipital pole, with a smoothly varying SNR proximal to this region. The temporal SNR of the occipital-parietal coil attained 35% higher SNR in the visual cortex than a whole-head coil.

4308

Computer 54

64-channel Double-Octagon Tx Head Coil for 7T Imaging

Tales Santini¹, Narayanan Krishnamurthy², Sossena Wood³, Shailesh Raval³, Yujuan Zhao³, Anthony Fischetti³, Minseok Koo³, Howard Aizenstein³, and Tamer Ibrahim³

¹University of Pittsburgh, Pittsburgh, PA, United States, ²Pittsburgh, PA, United States, ³University of Pittsburgh

This work presents the design of a 64-channel double-rowed head coil (16 octagons with 4 Tx channels on each octagon). The magnetic field (B_1) and the specific absorption rate (SAR) generated by the new coil were then compared with the TEM and 16-channel Tic Tac coils using Finite-Difference Time Domain (FDTD) simulations. Preliminary data shows significant improvements in all of performance parameters: coefficient of variation (CV) = 14.9% (field distribution) and maximum/minimum (Max/Min) = 2.45 (field intensity) across the whole head above and including the cerebellum; and peak/average SAR = 4.97/1.51 W/Kg/10g.

4309

Computer 55

Optimization of the Receive Performance of a Tight-Fit Transceiver Phased Array for Human Brain Imaging at 9.4T.

Nikolai I. Avdievich¹, Ioannis A. Giapitzakis¹, and Anke Henning^{1,2}

¹Max Planck Institute for Biological Cybernetics, Tübingen, Germany, ²Institute of Physics, Ernst-Moritz-Arndt University, Greifswald, Germany

Tight-fit ultra-high field (UHF) ($\geq 7T$) surface loop transceiver (TxRx)-phased arrays improve transmit (Tx) efficiency in comparison to Tx-only arrays built larger to accommodate for receive (Rx)-only array inserts. However, the number of elements in TxRx-arrays is restricted by the number of available RF Tx-channels (commonly 8 or 16), which limits the Rx-performance. A prototype of a 16-element array, which consists of 8 TxRx-surface loops circumscribing a head and 8 additional "vertical" Rx-only loops positioned in the center of each TxRx-loop perpendicularly, was constructed. This addition improves the Rx-performance substantially and has a minimal effect on both the Tx-efficiency and maximal local SAR.

Computer 56

Lightweight Size Optimized Printed Pediatric Receive Array

Joseph Corea¹, Balthazar Lechene¹, Shreyas Vasanaawala², Ana Claudia Arias¹, and Micheal Lustig¹

¹UC Berkeley, Berkeley, CA, United States, ²Stanford Hospital

The current landscape of pediatric body MRI lacks dedicated high-density arrays, especially for small children. Therefore many centers use existing arrays designed for adults. These arrays are much larger than the patients, reducing the effective number of elements. Adult arrays are heavy for children and are supported by additional padding, increasing the distance from the patient and reducing image quality. Here, we present an appropriately sized blanket-like array designed from patient data for torso and chest/abdominal imaging of 0-2 and 3-5 year olds respectively. This pediatric array is fabricated using screen-printed electronics to produce an extremely lightweight and flexible coil.

4311

Computer 58

Fast method to get an upper bound of the maximum SAR for body coil arrays

Ettore Flavio Meliadó^{1,2}, Alexander J.E. Raaijmakers^{1,3}, Peter R. Luijten¹, and Cornelis A.T. van den Berg¹

¹Center for Image Sciences, University Medical Center Utrecht, Utrecht, Netherlands, ²MR Code BV, Zaltbommel, Netherlands, ³Biomedical Image Analysis, Eindhoven University of Technology, Eindhoven, Netherlands

One of the most demanding challenges with ultra-high field MRI is the SAR_{10g} assessment during a multi-channel transmit MRI examination. A worst-case estimate is often used. In this work a fast method is presented to assess the upper bound of the maximum SAR_{10g} for body coil arrays with knowledge on only the power distribution among the channels. The performance is assessed for prostate imaging at 7T using our database with 23 realistic subject-specific models. The mean overestimation factor is 1.58 and the mean reduction in overestimation is 0.75 compared to a recently presented alternative estimation method.

Measurement of Phosphocreatine and BOLD Kinetics in the Lower Extremity Muscles using a Dual-Frequency Coil Array

Ryan Brown^{1,2}, Oleksandr Khagai^{1,2}, and Prodromos Parasoglou^{1,2}

¹Center for Advanced Imaging Innovation and Research (CAI2R), New York University School of Medicine, New York, NY, United States,

²Bernard and Irene Schwartz Center for Biomedical Imaging, New York University School of Medicine, New York, NY, United States

MRI provides the unique ability to study metabolic and microvasculature functions in skeletal muscle using phosphorus and proton measurements. However, the low sensitivity of these techniques can make it difficult to capture dynamic muscle activity due to the temporal resolution required for kinetic measurements during and after exercise tasks. We developed a dual-nuclei coil array to enable proton and phosphorus MRI of the human lower extremities with SNR more than double that of a birdcage coil in the gastrocnemius muscles. This enabled the local assessment of phosphocreatine recovery kinetics following a plantar flexion exercise using an efficient sampling scheme with a 6 s temporal resolution. The integrated proton array demonstrated image quality approximately equal to that of a clinical state-of-the-art knee coil, which enabled fat quantification and dynamic blood oxygen level-dependent measurements that reflect microvasculature function.

29-channel Receive-only Dense Dipole Head Array for 7T MRI

Bei Zhang¹, Gang Chen^{1,2}, Martijn Cloos¹, Zidan Yu^{1,2}, Jerzy Walczyk¹, Christopher Collins^{1,2}, Ryan Brown¹, Riccardo Lattanzi^{1,2}, Daniel Sodickson^{1,2}, and Graham Wiggins¹

¹Bernard and Irene Schwartz Center for Biomedical Imaging, Department of Radiology, New York University School of Medicine, New York, NY, United States, ²The Sackler Institute of Graduate Biomedical Sciences, New York University School of Medicine, New York, NY, United States

Inspired by recent theoretical work indicating that z-oriented currents could capture most of the optimal SNR and outperform loops in reception at high frequencies, we constructed and evaluated a close-fitting dense dipole receive-only head array with 29 elements. The array was combined with a dual-channel transmit birdcage for experiments. SNR was good throughout a head phantom at 7T and outperformed a commercial head coil in regions above and below the center. Future work will focus on detuning mechanisms for dipole elements to enable safe in-vivo measurements.

4315

Computer 61

An open 8-channel pTx coil for 7-Tesla MRI of the knee and ankle joints at multiple postures

Ewald Weber¹, Craig Engstrom¹, Kieran O'Brien², Aurelien Destruel¹, Bassem Henin³, Jin Jin¹, and Stuart Crozier¹

¹University of Queensland, St Lucia, Australia, ²Siemens Ltd, Brisbane, Australia, ³American University of the Middle East, Kuwait

This paper presents the initial *in vivo* imaging results from a new open 8-channel pTx transceive array designed and constructed for 7 T MRI of the knee and ankle joints. The open design of the coil provides easy access and conformable accommodation of both joints, while enabling the joints to be imaged at multiple angles for enhanced pathological assessment. With individualized RF shims, the array provided full coverages and uniform excitations for both joints, demonstrated with high quality 2D TSE and 3D GRE (DESS and MEDIC) images.

Computer 64

Metamaterial Double-loop RF Head Coil for UHF MRI: A Numerical Evaluation and Experimental Verification at 7T

Elizaveta Motovilova¹, Yang Gao^{2,3}, Zhihua Ren¹, Xiaotong Zhang^{2,3}, and Shao Ying Huang^{1,4}

¹Engineering Product Development, Singapore University of Technology and Design, Singapore, Singapore, ²Interdisciplinary Institute of Neuroscience and Technology, Zhejiang University, Hangzhou, People's Republic of China, ³College of Biomedical Engineering & Instrument Science, Zhejiang University, Hangzhou, People's Republic of China, ⁴Department of Surgery, National University of Singapore, Singapore, Singapore

This study presents a numerical evaluation of a novel RF coil array for human head imaging at 7T. The 8-element coil was developed using a metamaterial concept. As the main advantage of a metamaterial transmission line is that the uniformity of RF-magnetic near field does not depend of the TL's physical length, we applied this meta-TL concept to a loop in order to achieve a larger coverage of B_1^+ -field. Numerical comparison to conventional designs demonstrate an improved B_1 -field homogeneity of the proposed coil. Preliminary experimental studies show a reasonable agreement with simulations.

4319

Computer 65

The potential of a 256-Channel receive-only Array Coil for accelerated Cardiac Imaging at 3T

Bernhard Gruber^{1,2}, Arjan D. Hendriks¹, Cezar B.S. Alborahal³, Bas Brussen³, Tim Leiner¹, Gustav Strijkers¹, Dennis W. J. Klomp^{1,3}, and Martijn Froeling¹

¹Department of Radiology, University Medical Center Utrecht, Utrecht, Netherlands, ²Institute of Biomedical Mechatronics, Johannes Kepler University, Linz, Austria, ³MR Coils B.V., Zaltbommel, Netherlands

High-density coil arrays can be used to accelerate MRI. Here we present the results from measurement-based extrapolations of a 256 Channel Cardiac Array Coil obtained by 16 sequential scans of a 16 Channel Array to assess acceleration performance and sensitivity constraints for 3T MRI. With element sizes of 55 mm x 33 mm, tissue load remains dominant at the 3T Larmor frequency of water, while SENSE accelerations can go up to 20-fold at low g-factors. These results motivate the design of a 256 channel cardiac array for accelerated 3T MRI.

4320

Computer 66

A bent dipole antenna and 4-channel loop array for 1H/31P brain application at 3 T MRI

Suk-Min Hong¹, Chang-Hoon Choi¹, Jörg Felder¹, Arthur W. Magill^{1,2}, and N. Jon Shah^{1,3}

¹Institute of Neuroscience and Medicine - 4 Medical Imaging Physics Forschungszentrum Juelich GmbH, Juelich, Germany, ²Current Address: Medical Physics in Radiology, German Cancer Research Centre (DKFZ), Heidelberg, Germany, ³Department of Neurology, Faculty of Medicine, RWTH Aachen University, JARA, Aachen, Germany

A dipole antenna achieves good isolation from a loop coil when it is located over the centre of a loop coil. Such an arrangement can be used as a dual-tuned coil, by tuning the dipole and the loop to the ¹H and X frequencies, respectively. At 3 T, however, the length of a dipole antenna is too long to be of use for brain applications. In this study, we bent the dipole antenna around the head to overcome the length problem. We then evaluated the feasibility of combining two dipole antennae and a 4-loop array for ¹H/³¹P application.

4321

Computer 67

PIN-diode switched dual-tuned RF coils

YongHyun Ha¹, Arthur W. Magill^{1,2}, Chang-Hoon Choi¹, and N. Jon Shah^{1,3}

¹Institute of Neuroscience and Medicine - 4, Forschungszentrum Juelich, Juelich, Germany, ²Current Address: Medical Physics in Radiology, German Cancer Research Centre (DKFZ), Heidelberg, Germany, ³Faculty of Medicine, Department of Neurology, JARA, RWTH Aachen University, Aachen, Germany

In this work we investigate the transmit and receive performance of a probe employing such switching, using a simple loop coil tuned to 45 and 169 MHz for the detection of ²³Na and ¹H, respectively, at 4T. PIN diode switched-capacitor networks work well under forward bias, but perform poorly in reverse bias. Specifically, a high reverse bias voltage is required to allow operation over a realistic range of RF transmit voltages. This makes such switched-capacitor networks unsuitable for use in transmit probes. However, they can be used in receive-only probes, because the voltages present on the loop are much smaller.

4322

Computer 68

Folded four-ring double-tuned birdcage coil design

YongHyun Ha¹, Chang-Hoon Choi¹, and N. Jon Shah^{1,2}

¹Institute of Neuroscience and Medicine - 4, Forschungszentrum Juelich, Juelich, Germany, ²Faculty of Medicine, Department of Neurology, JARA, RWTH Aachen University, Aachen, Germany

In this work, we designed a double-tuned ¹H/²³Na four-ring birdcage coil with a modification that entailed folding the outer end-rings by 90 degrees to overcome the available space limitation. And ²³Na SNR of the folded four-ring birdcage coil reached more than 93% of that obtained with the single-tuned birdcage coil. One benefit of folded four-ring birdcage coil compared to conventional four-ring birdcage coil is that there is no space restriction. This helps to build double-tuned coils that have a smaller diameter, leading to higher filling factors.

4323

Computer 69

Half-wave Cavity Resonator for MR Coils Cable Assembly Testing

Victor Taraçila¹, Louis Vannatta¹, Robert Rainey¹, Miguel Navarro¹, Aleksey Zemskov¹, and Fraser Robb¹

¹GE Healthcare Coils, Aurora, OH, United States

In MR coils or MR table there are multiple cables. Their presence is not desirable because they distort the B1 field; therefore multiple RF traps are distributed along the cable length to minimize induced cable currents. Tuning and performance of the MR cable traps, also called cable baluns, on the cable are always difficult to predict, because the cable shape and position may vary. A coaxial half-wave cavity resonator is shown to be a precise tool to test cable balun assembly. It facilitates precise measurement of a balun's coupling to the cable, its loss, and coupling to neighboring baluns.

4324

Computer 70

[A General Approach to Interfacing Multi-Nuclear RF Coils](#)

karthik lakshmanan¹, Ryan Brown¹, Christopher Collins¹, and Graham C Wiggins¹

¹NYU School of Medicine, Newyork, NY, United States

RF coils for multi-nuclear imaging require scanner-specific front-end interfaces that can limit their compatibility to one particular scanner platform. On the other hand, an intermediate interface that allows legacy coil compatibility with modern scanner architecture can be valuable in large institutions that operate a variety of scanners. In this work we describe the tools to build an intermediate interface with electronically controlled low-loss RF and DC signal pathways to provide a flexible means to route signals between the coil and scanner. While the tools are generally applicable to a variety of platforms, we focus on enabling compatibility between legacy multinuclear coils and a current scanner platform.

4325

Computer 71

[Initial tests of a 4-channel building block for a local 32-channel Rx-only body coil at 7T](#)

Stefan HG Rietsch^{1,2}, Stephan Orzada¹, Sarah Handtke¹, Sascha Brunheim^{1,2}, Mark E Ladd^{1,3}, and Harald H Quick^{1,2}

¹Erwin L. Hahn Institute for MR Imaging, University of Duisburg-Essen, Essen, Germany, ²Highfield and Hybrid MR Imaging, University Hospital Duisburg-Essen, Essen, Germany, ³Medical Physics in Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany

Receive-only (Rx) radiofrequency (RF) arrays are widely used in the clinical environment at 1.5 and 3T. At 7T, there is by default no integrated RF body coil. Yet, a 32-channel Tx/Rx body coil built into a 7T MRI system was recently presented. Consequently, this paves the way for 7T body imaging using this coil for Tx and local coils to receive the RF signal. In this work we present a 32-channel Rx-only coil for 7T and evaluate SNR boost and acceleration capabilities of one 4-channel building block.

[Optimization of Remote RF Transmit Coil Elements and Arrays for 7T UHF Body MRI](#)

Stefan HG Rietsch^{1,2}, Stephan Orzada¹, Andreas K Bitz³, Marcel Gratz^{1,2}, Mark E Ladd^{1,3}, and Harald H Quick^{1,2}

¹Erwin L. Hahn Institute for MR Imaging, University of Duisburg-Essen, Essen, Germany, ²Highfield and Hybrid MR Imaging, University Hospital Duisburg-Essen, Essen, Germany, ³Medical Physics in Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany

Remote radiofrequency (RF) body coils are broadly used as built-in body RF coils for signal transmission in clinical MR systems at 1.5 and 3T. For ultra highfield MR at 7T, remote body coils in conjunction with pTx systems have recently been presented. In this work we present a modified micro stripline RF element with meanders and investigate the performance of a 7T remote RF transmit array for body imaging applications featuring 8 of these elements concerning coupling, degrees of freedom within the B₁⁺ fields, distribution of losses, power efficiency, and SAR efficiency.

[A comparative study of coil winding techniques of a full body 1.5 T MgB₂ based MRI magnets.](#)

Abdullah Al Amin¹, Bhumi Bhusal², Tanvir Noor Baig², Robert Deissler², Laith Sabri², Ozan Akkus¹, and Michael Martens²

¹Mechanical & Aerospace Engineering, Case Western Reserve University, Cleveland, OH, United States, ²Department of Physics, Case Western Reserve University, Cleveland, OH, United States

Control of strain development in an MgB₂ based full body MRI magnet is a challenge towards realizing a conduction cooled system. It is possible to alter the strain development in an MRI magnet by modifying the coil winding support conditions and by varying the winding stress on the wire across the layers. A multiscale multiphysics model is employed to study the strain comparison by varying support conditions and winding prestress. Results conclude, radial support with constant winding prestress generates about 50% less stress and 42% less strain compared to no mandrel support.

Computer 74

[Concurrent use of 4 gradient axis enables eddy current compensation of an unshielded gradient insert coil](#)

Tijl A van der Velden¹, Quincy van Houtum¹, Vincent O. Boer^{1,2}, Peter R. Luijten¹, Jeroen C.W. Siero^{1,3}, and Dennis W.J. Klomp¹

¹Radiology, University Medical Center Utrecht, Utrecht, Netherlands, ²Danish Research Centre for Magnetic Resonance, Copenhagen University Hospital Hvidovre, Denmark, ³Spinoza Center for Neuroimaging, Amsterdam, Netherlands

In this work, a method is presented where a whole-body gradient system corrects for eddy currents induced by an unshielded gradient insert coil. A single-axis unshielded gradient breast insert coil was positioned in a 7 tesla whole body MR system. Field cameras were used to analyze the eddy currents and validate the proposed method.

4329

Computer 75 [A lightweight gradient insert coil for high resolution brain imaging](#)Tijl A van der Velden¹, Carel C. van Leeuwen¹, Erik R. Huijting¹, Martino Borgo², Peter R. Luijten¹, Dennis W.J. Klomp¹, and Jeroen C.W. Siero^{1,3}¹Radiology, University Medical Center Utrecht, Utrecht, Netherlands, ²Futura Composites B.V., Heerhugowaard, Netherlands, ³Spinoza Center for Neuroimaging, Amsterdam, Netherlands

A lightweight insert gradient coil was constructed for high resolution brain imaging. The coil was designed as a single-axis unshielded coil to accelerate EPI readouts. The resulting coil weighs 45 kg and can be quickly positioned in the scanner by two persons. Theoretically, a gradient strength of 210 mT/m can be achieved with a slew rate of 1088 T*m⁻¹*s⁻¹ when driven at 400V/600A. In a 7 tesla scanner, an efficiency of 0.35 mT*m⁻¹*A⁻¹ with a slew rate of 800 T*m⁻¹*s⁻¹ was measured. Experiments on five healthy volunteers resulted in no experiences of nerve stimulation.

4330

Computer 76 [Global and dynamic shimming with the scanner's inbuilt shim system and a custom-made multi-coil setup at 9.4 T](#)Ali Aghaeifar^{1,2}, Irena Zivkovic¹, Christian Mirkes¹, Theodor Steffen¹, and Klaus Scheffler^{1,3}¹Max Planck Institute for Biological Cybernetics, Tübingen, Germany, ²IMPRS for Cognitive and Systems Neuroscience, University of Tübingen, Tübingen, Germany, ³Department of Biomedical Magnetic Resonance, University of Tübingen, Tübingen, Germany

The homogenization of static magnetic field (B₀) is necessary for MR imaging. The unwanted B₀ inhomogeneity becomes more pronounced in ultra high field, and the scanner's inbuilt shim setup can not compensate the B₀ fluctuation as is needed. Here we propose to use combined setup of the multi-coil approach and the scanner's shim setup to achieve higher homogeneity of B₀ field. We employed custom-built multi-coil for slice-wise shimming in combination with the scanner's shim setup for global shimming. The results show improvement about 50% compare to dynamic shimming alone in the most of the slices.

4331

Computer 77 [A Compact Affordable Three-Bore Cryogen-Free Superconducting Magnet for Extremity Imaging](#)Shahin Pourrahimi¹, Jerome L. Ackerman^{2,3}, John E. C. William¹, Nadder Pourrahimi¹, and Alexey Kaplan¹¹Superconducting Systems, Inc., Billerica, MA, United States, ²Martinos Center, Dept of Radiology, Massachusetts General Hospital, Charlestown, MA, United States, ³Department of Radiology, Harvard Medical School, Boston, MA, United States

In a project to develop a compact MRI limb scanner for orthopedic and metabolic bone disease applications we developed a three-bore 1.5T magnet with the following design goals: ability to operate the magnet in a small point-of-care space, elimination of liquid cryogens for installation or operation, a comfortable patient experience while scanning knees, ability to tilt the magnet to accommodate patients rather than requiring patients to accommodate to the magnet, and capability for conventional and solid state proton and phosphorus MRI for metabolic bone disease assessment.

4332

Computer 78 [The numerical limitation of Multi-coil shim and Orthogonal RF-Shim coil](#)Jiazheng Zhou¹, Pu-Yeh Wu¹, Jason P. Stockmann^{2,3}, and Fa-Hsuan Lin^{1,4}¹Institute of Biomedical Engineering, National Taiwan University, Taipei City, Taiwan, ²A. A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Charlestown, MA, United States, ³Harvard Medical School, Boston, MA, United States, ⁴Department of Neuroscience and Biomedical Engineering, Aalto University, Espoo, Finland

We used numerical simulations to study the relationship between attainable field homogeneity and the number as well as the orientation of shim coils in a multi-coil shim array. We found that, constrained the same number of shim coils, arranging shim coils in three orthogonal directions can provide the best shimming. Inspired by simulations, we propose a design of the integrated RF-shim coil at 3 T to place shim and RF coil orthogonally.

4333

Computer 79 [Controlled E-peak field gradient coil](#)Hector Sanchez Lopez^{1,2}, Luca Zilberti³, Oriano Bottauscio³, Mario Chiampi^{3,4}, Xiaodong YANG², and Yajie XU²¹ARKFIELD PTY LTD, Brisbane, Australia, ²Medical Imaging Department, Suzhou Institute of Biomedical Engineering and Technology (SIBET), Suzhou, People's Republic of China, ³Division of Metrology for Quality of Life, Istituto Nazionale di Ricerca Metrologica (INRIM), Torino, Italy, ⁴Energia Department, Politecnico di Torino, Torino, Italy

This work presents a new shielding method capable to reduce E-peak field values by minimizing the infinite norm of the induced current density. The target volume ("organ") is surrounded by a conductive surface "shell" where the infinite norm of the induced current density is minimized thereby producing a uniform distribution of the E-field inside the target volume and its surrounding. The method was effectively applied in the design of a whole body gradient coil with E-field control. E-field reduction larger than 10% are registered in a human phantom model. Further reductions in E-field is possible by compromising the coil performance.

4334

Computer 80 [Design of an MRI Gradient Field Exposure System for Medical Device Testing](#)Daniel J Martire¹, William B Handler¹, Colin M McCurdy¹, Justin C Peterson¹, and Blaine A Chronik¹¹Physics and Astronomy, Western University, London, ON, Canada

A method to design and numerically optimize a gradient field exposure system for testing medical devices is presented. Magnet windings are modelled as small current elements in space, and dimensions of a coil capable of emulating the switching rate and strength of MRI gradient fields are chosen by a grid search of parameter space. A buildable option capable of achieving 1.2% homogeneity over an 8 cm DSV, a slew rate of 246 T/s, and a maximum field shift of 68 mT was determined to be sufficient for our application and for satisfying relevant elements of ISO/TS 10974.

- 4335 Computer 81 Very low field MRI setup for brain imaging
Reina Ayde¹ and Claude Fermon¹

¹Commissariat à l'energie Atomique, Saclay, France, Metropolitan

Mixed sensors coupled to tuned flux transformer could be more effective than classical tuned coils in detecting MRI signals on a very low field range. In order to compare later on their effectiveness, first, a very low field head MRI system (8.4 mT) is developed. Homogeneity, gradients strength, excitation and reception coils were adjusted. A homogeneity of 84 ppm was achieved in a quasi-open configuration. The amplitude of each gradient was 100 times lower than at high field but sufficiently high to achieve a resolution of less 2 mm x 2 mm x 2 mm. Images with a 3D imaging acquisition without pre-polarization technique nor magnetic shielding room were achieved.

- 4336 Computer 82 A new method for optimizing performances of gradient coils based on singular value decomposition and genetic algorithm
Koki Matsuzawa¹, Katsumi Kose¹, and Yasuhiko Terada¹

¹Institute of Applied Physics, University of Tsukuba, Tsukuba, Japan

Designing gradient coils with arbitrary geometries has been realized by matrix inversion optimization techniques. Use of a truncated singular value decomposition (SVD) is promising because magnetic field accuracies are controlled by choosing the appropriate SVD eigenmodes. However, in the SVD method, the gradient performances, such as inductance and power dissipation, cannot be optimized. Here we proposed a new strategy to optimize a desired coil performance. A key feature is the use of a genetic algorithm to optimize the appropriate combination of SVD eigenmodes. The concept is demonstrated for a biplanar geometry, and would be readily applicable to arbitrary geometries.

- 4337 Computer 83 Oval gradient coils for a vertical magnetic field MRI
Koki Matsuzawa¹, Katsumi Kose¹, and Yasuhiko Terada¹

¹University of Tsukuba, Tsukuba, Japan

Small gradients are ideal in performance. Vertical-field MRI systems use biplanar gradient coils, and the coil sizes are no smaller than the magnet gap. Here we propose the oval geometry for gradient coils for vertical-field MRI to increase coil performance. Oval coils could be smaller than biplanar coils with maintaining the high accessibility and gradient linearity. Moreover, oval coils are preferable from the viewpoint of heating problems, because the gradient heat is efficiently cooled by air. In this study, we designed and constructed oval gradient coils for a 0.3 T, open MR scanner, and demonstrated the validity of the concept.

- 4338 Computer 84 B0 shimming in a small volume at 9.4T – irregular coil geometry setup vs. loop coil setup
Irena Zivkovic¹, Iliya Tolstikhin², Bernhard Schoelkopf², and Klaus Scheffler^{1,3}

¹High Field MRI, Max Planck Institute for Biological Cybernetics, Tuebingen, Germany, ²Empirical Inference, Max Planck Institute for Intelligent System, Tuebingen, Germany, ³Dept. for Biomedical Magnetic Resonance, University of Tuebingen, Tuebingen, Germany

At high magnetic fields B0 inhomogeneities are more pronounced and B0 shimming becomes very important. Dynamic or slice based shimming always provides better results than global or shimming in a volume. For shimming in a small volume, we propose a setup composed of irregularly shaped coils. Performances of the proposed setup are compared to performances of the configuration composed of only loop elements. The setup with irregular coils shows improved performances over the setup containing only loop elements. Future work should validate performances of the proposed setup on different volume sizes and different brain's B0 maps.

- 4339 Computer 85 Measuring Slice Profiles Across the Industry With the ACR Phantom
Moriel NessAiver¹

¹Simply Physics, Baltimore, MD, United States

As part of mandated yearly performance evaluations on over 120 GE, Siemens, Philips and Toshiba 1.5T scanners, the ACR phantom was used to make 2555 measurements of RF slice profiles and thicknesses. Aggregated slice profiles are plotted showing clear differences between vendors both in terms of 'squareness' and FWHM thickness. With a target slice thickness of 5.0 mm the measured thicknesses ranged from 4.21 to 6.65 mm! The affect that interslice gap has on measured profiles (RF crosstalk) is demonstrated for T1 weighted sequences. A very surprising dependence of measured thickness on slice position on the ACR phantom is demonstrated.

- 4340 Computer 86 Continuous SWIFT: Analog Leakage Compensation Utilizing an Embedded System
Jonathan Weine¹, Florian Maier¹, Daniel Polak¹, and Reiner Umathum¹

¹German Cancer Research Center, Heidelberg, Germany

Methods for simultaneous excitation and acquisition enable measurements of signals with ultrashort T_2^* relaxation times. In this work, a method was developed and implemented to analogously compensate leakage of the excitation pulse into the receiver channel due to imperfections in coil tuning and the quadrature hybrid utilized in cSWIFT setups. The setup was enhanced with an embedded system, a vector modulator and a summing unit to subtract the leakage from the signal. Feasibility of the real-time compensation was demonstrated. Leakage was reduced by up to -40 dB.

High field MRI in-vivo setup for observing brain plasticity in Eastern Fenced Lizards

Yee Eun Kim¹, Thomas Neuberger², Gangchea Lee¹, and Lara LaDage³

¹PSU, University Park, PA, United States, ²HUCK Institute, PSU, University Park, PA, United States, ³PSU, Altoona, PA, United States

In this work, Eastern Fenced lizards, a non-model species known for high neurogenesis, were used to explore the extent of adult brain plasticity after exposing the animals to a complex environment and inmates. To conduct this study a MR setup for *in-vivo* lizard imaging was designed, constructed and tested. High resolution baseline in-vivo three dimensional lizard brain MR microscopy data sets were acquired and analyzed. The high quality of the images will allow to detect any brain volume changes after exposing the lizards to the enriched environment and having them scanned a second time.

Using machine learning with dynamic exam block lengths to decrease patient wait time and optimize MRI schedule fill rate.

Michael C. Muelly¹, Paul B. Stoddard¹, and Shreyas S. Vasanwala¹

¹Department of Radiology, Stanford University, Stanford, CA, United States

MRI has advantages compared to other radiologic modalities in terms of tissue visualization, versatility, and lack of risks associated with ionizing radiation. However, cost of MRI is often the limiting factor favoring other modalities. Using historical scanner data and a Monte Carlo type discrete event simulation, we investigated how estimating exam length on the basis of patient demographics and dynamic block lengths affect mean patient wait times and schedule fill rate. In our simulation we are able to significantly lower mean patient wait times and optimize the schedule fill rate, which would theoretically result in lower cost per exam while enhancing patient satisfaction.

4344

Computer 90

Automated quality control of MR images using deep convolutional neural networks

Michael C. Muelly¹, Paul B. Stoddard¹, and Shreyas S. Vasanwala¹

¹Department of Radiology, Stanford University, Stanford, CA, United States

The complexity of MR scanners results in significant variability in the quality of images produced, in some cases requiring clinical expertise to recognize suboptimal images. Deep convolutional neural networks are an emerging technique with potential clinical applications. We aim to investigate whether deep convolutional neural networks could be trained for three MR image quality control classification tasks: 1) Recognize adequacy of MR elastography wave propagation, 2) determine whether rectal gas susceptibility artifact obscuring the prostate is present, and 3) determine scan technique in unlabeled images. Using the Inception v4 deep convolutional neural network we found high classification accuracy for two out of these three problems suggesting the potential to automate certain aspects of MR quality control.

Real time gain stabilization for PET detectors in PET/MR

Floris Jansen¹, Mark Fries¹, Tuoyu Cao¹, Mehdi Khalighi², and Chang Kim¹

¹GE Healthcare, Waukesha, WI, United States, ²GE Healthcare, Palo Alto, CA, United States

Accurate quantitation in PET requires good stability of the detector gain. The challenging thermal environment of the detector in a PET/MR system (proximity to gradients, induced eddy currents, heat from RF shield, ...) makes accurate temperature compensation important. Current solutions rely on characterization of detector response together with real time temperature measurement for a predictive (open loop) gain control. This work presents a method of gain control that operates in real time by analyzing spectral information of singles events, permitting closed loop gain control in the presence of temperature gradients or count rate variations.

Cost-effective RF Signal Transmit-Receive chain at 9.5mT

Samarth Singh¹, Darshan Shivaramu Keelara¹, Chennagirai Rajarao Padma¹, Rashmi Rao¹, Imam Ahmed Shaik¹, and Sairam Geethanath¹

¹Medical Imaging Research Centre, Dayanand Sagar Institutions, Bangalore, India

A cost-effective RF Signal Transmit-Receive chain with independent transmit and receive coil was designed with inexpensive off-the-shelf electronic components, costing around 175 US dollars. A Direct Digital Synthesizer (DDS) module was controlled using an Arduino Uno R3 microcontroller board. RF pulses were timed to precision using Arduino IDE, and the 405 kHz sine wave required to operate a 9.5 mT system was pulsed to a transmit coil. This signal was detected successfully by a custom-made surface coil. While the transmit, pulse was at 1.12Vpp from the DDS module, the surface coil successfully picked up a 1.75 Vpp signal.

Unified Coils (UNIC) for Simultaneous RF Reception and Targeted Local B0 Shimming

HUI HAN¹, John Stager¹, Hsin-Jung Yang¹, Na Zhang¹, Sizhe Guo¹, Zhuoqi Li¹, Yicheng Wang¹, and Debiao Li¹

¹Biomedical Imaging Research Institute, Cedars-Sinai Medical Center, LOS ANGELES, CA, United States

We propose a new general MR coil concept with integrated RF and B₀ shimming applicable to almost all MRI coils and systems. Innovative geometrical decoupling methods are proposed to bring the distance between separate shim and RF loops to zero millimeters and to make shim loops physically free from the RF loops. Therefore, both RF and shim coils can be in close proximity to the subject and be designed independently to maximize the performance of each function. It also opens a new window to integrate shim and RF coils or other coils in the constricted scanner bore space.

Computer 96

Design and Construction of Shielded Enclosures for MRI

Jonathan Howard¹ and Rexford Newbould¹

¹Imanova Ltd, London, United Kingdom

A significant limiting factor for electronic devices within the scanner room is the electromagnetic interference (EMI) that they generate. Also, electromagnetic radiation from the scanner can interfere with the safe operation of electronics in close proximity to the scanner. We describe the development of an approach that enables researchers to fabricate inexpensive and reliable shielded enclosures without access to extensive engineering facilities. Our investigation explores the relative advantages and disadvantages in the design and construction of three different shielded enclosures and concludes with a performance evaluation by measuring the frequency dependent attenuation of electromagnetic signal intensity.

A multi-parametric MRI-based radiomics approach to predict the high level of microsatellite instability in colorectal cancer

Zaiyi Liu¹, Yanqi Huang¹, Xin Chen², Zhongping Zhang³, Lan He¹, and Xiaomei Huang¹

¹Radiology, Guangdong General Hospital, Guangzhou, People's Republic of China, ²Radiology, Guangzhou First Hospital, Guangzhou, People's Republic of China, ³MR Research China, GE Healthcare, Beijing, People's Republic of China

Microsatellite instability (MSI) is the condition of genetic hypermutability that results from impaired DNA mismatch repair (MMR). High levels of microsatellite instability (MSI-H) is regarded as a prognostic marker and predictor of the response to chemotherapy in colorectal cancer (CRC). This study presented a multi-parametric radiomics classifier for preoperative and individualized prediction of MSI-H status in CRC patients. The potential application of this radiomics approach may aid the prognostic evaluation and decision-making in CRC patients.

- 4352 Computer 2 [Magnetic Resonance Spectroscopic Early Predictors of 2-Year Progression Free Survival in IDH Mutated WHO II and III Gliomas](#)
Min Zhou¹, Raymond Huang², Huijun Liao¹, Benjamin Rowland¹, Yue Zhou¹, Nils Arvold³, and Alexander Lin¹

¹Center for Clinical Spectroscopy, Brigham and Women's Hospital, Boston, MA, United States, ²Radiology, Brigham and Women's Hospital, Boston, MA, United States, ³Radiation Oncology, Brigham and Women's Hospital, Boston, MA, United States

Most MR spectroscopy studies of patients with IDH-mutated gliomas have focused on the sensitivity and specificity of the 2-hydroxyglutarate measures but none that have examined the predictive value of 2HG in comparison to other brain metabolites for treatment outcome. This prospective longitudinal study measured MRS at baseline and two time points after radio/chemotherapy of IDH-mutated gliomas. Results showed that Cho/NAA shows the greatest predictive value followed by Cho/Cr, NAA/Cr, and Lac/Cr ratios but that all three time points 2HG levels were not predictive of outcome demonstrating that it is likely reflective of pathways distinct from membrane proliferation.

- 4353 Computer 3 [Radiation-induced changes in normal-appearing brain in patients with nasopharyngeal carcinoma: a MR T1p imaging study](#)
Xiang Xiao¹, Yikai Xu¹, Yuankui Wu¹, Yingjie Mei², and Queenie Chan³

¹Medical Imaging Center, Nanfang Hospital of Southern Medical University, Guangzhou, People's Republic of China, ²Philips Healthcare, Guangzhou, People's Republic of China, ³Philips Healthcare, Hongkong, People's Republic of China

Radiation encephalopathy is the primary complication in patients with nasopharyngeal carcinoma (NPC) following radiotherapy (RT). In order to detect early radiation-induced alterations in the brain of NPC patients after RT, we recruited NPC patients before RT and after RT with normal-appearing brain for MR T1p examinations. We found abnormal microstructural changes of gray matter and white matter in NPC patients after RT can be detected by MR T1p even when routine MRI findings are negative. MR T1p may be used to predict early radiation-induced alterations of the brain following RT for NPC patients.

- 4354 Computer 4 [Using MRI to investigate the impact of radiation-induced damage on promoting tumor growth in a mouse model of brain metastasis](#)
Amanda M Hamilton¹, Eugene Wong², and Paula J Foster^{1,2}

¹Imaging Research Laboratories, Robarts Research Institute, London, ON, Canada, ²Medical Biophysics, University of Western Ontario, London, ON, Canada

Whole brain radiotherapy (RT) is the standard of care for breast cancer patients with multiple brain metastases but there are multiple negative consequences associated with the irradiation of normal brain tissue. In our study we investigated the influence that RT-induced damage of healthy brain has on the arrest and growth of metastatic breast cancer cells in a mouse model of breast cancer brain metastasis. We observed that irradiated but otherwise healthy neural tissue had an increased propensity to support metastatic growth compared to control. Elucidating the impact of RT on normal neural tissue could have implications in clinical patient management.

¹Wright Center of Innovation in Biomedical Imaging, Department of Radiology, The Ohio State University, Columbus, OH, United States, ²Department of Internal Medicine, The Ohio State University, Columbus, OH, United States, ³Department of Urology, The Ohio State University, Columbus, OH, United States, ⁴Center for Biostatistics, The Ohio State University, Columbus, OH, United States, ⁵Department of Pathology, The Ohio State University, Columbus, OH, United States, ⁶Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA, United States, ⁷Pennington Biomedical Research Center, Baton Rouge, LA, United States

This study is to correlate the degree of tumor heterogeneity in Apparent Diffusion Coefficient (ADC) at baseline with chemotherapeutic response in bladder cancer patients. MRIs of twenty muscle-invasive bladder cancer patients were performed with Diffusion weighted MRI (DWI). Freehand ROIs were placed on the whole tumor volume on ADC maps to obtain a dataset of voxel-wise ADC values for each patient. Histogram analysis was performed on each patient's ADC dataset to calculate uniformity (U) and entropy (E) at baseline. These quantities were then correlated with the patient's chemotherapeutic response. Our data showed that there was a strong correlation of tumor heterogeneity, which is characterized by U and E, and the patient's chemotherapeutic response. While U was significantly higher, E was significantly lower in responders (both $P < 0.01$) compared to non-responders. In conclusion, quantification of tumor ADC heterogeneity can provide useful information that enables the ability to predict chemotherapeutic response prior to the treatment, to improve the patient outcomes.

- 4356 Computer 6 [Simultaneous imaging of tumor size with contrast-enhanced MRI and response to therapy with extracellular pH readout from BIRDS](#)

¹Cardiff University School of Medicine, Cardiff, United Kingdom, ²Radiology and Biomedical Imaging, Yale School of Medicine, New Haven, CT, United States, ³Biomedical Engineering, Yale University, New Haven, CT, United States, ⁴Neurology, Henry Ford Hospital, Detroit, MI, United States

Acidic extracellular pH (pHe) of gliomas promotes tumor growth and builds resistance to therapy. Thus, to monitor therapeutic response, we used Biosensor Imaging of Redundant Deviation in Shifts (BIRDS), to generate pHe maps of rat brains bearing U251 tumors. Upon TmDOTP5-infusion, MRI identified tumor boundary and BIRDS imaged the intratumoral and peritumoral pHe gradient (DpHe). Two weeks post implantation of U251 glioma cells, animals were either treated with temozolomide (40 mg/kg) or were left untreated. The results of both terminal and longitudinal studies suggest that temozolomide therapy hinders tumor growth and normalizes intratumoral pHe.

- 4357 Computer 7 [Anatomical sites' dependency of 3.0 T whole-body MRI's signal fat fraction and apparent diffusion coefficient in multiple myeloma focal lesions](#)

HCC treated with 90Yttrium radioembolization: can pre-treatment and 6week post-treatment volumetric ADC histogram measurements predict subsequent tumor response?

Sonja Gordic^{1,2}, Mathilde Wagner^{1,3}, Riccardo Zanato¹, Stefanie Hectors¹, Cecilia Besa¹, Edward Kim⁴, and Bachir Taouli^{1,4}

¹Translational and Molecular Imaging Institute, New York, NY, United States, ²Institute of Diagnostic and Interventional Radiology, University Hospital Zurich, Zurich, Switzerland, ³Radiology, Groupe Hospitalier Pitié Salpêtrière, Paris, France, ⁴Department of Radiology, Icahn School of Medicine at Mount Sinai, New York, NY, Switzerland

We evaluated the potential of volumetric ADC histogram measurements (vADC) obtained pre- and 6 weeks (6w) post-treatment for prediction of HCC response to ⁹⁰Yttrium radioembolization (RE). 22 patients underwent MRI at baseline and 6w after RE using a routine liver MRI protocol including DWI. Tumor response was assessed by mRECIST at 6 months post treatment. vADC mean, median and mode obtained at 6w post-treatment were significantly different between patients with partial/complete response vs. those with stable/progressive disease, and were a significant predictor of complete tumor response at 6 months, with vADC mode performing best. Pre-treatment vADC did not have any predictive value for response.

We assessed the performance of various imaging response criteria for the prediction of complete pathologic necrosis (CPN) of hepatocellular carcinoma post locoregional therapy on liver explant. Patients who underwent liver transplantation after locoregional therapy were included in this retrospective study. All patients underwent MRI using routine liver protocol within 90 days of liver transplant. RECIST, mRECIST, EASL, percentage of necrosis on subtraction images, and DWI (signal intensity and ADC) were assessed. CPN was retrospectively assessed in all tumors at histopathology. mRECIST, EASL, percentage of necrosis and signal intensity on DWI were all significant predictors of CPN while RECIST and ADC criteria were not.

We correlated tumor stiffness (TS) measured with MR elastography (MRE) to degree of tumor enhancement and necrosis on contrast-enhanced T1-weighted imaging (CE-T1WI) in hepatocellular carcinomas (HCC) treated with locoregional therapy. Patients with HCC who underwent locoregional treatment and controls with newly diagnosed untreated HCC were included. TS values were obtained by placing regions of interest (ROIs) over HCCs on stiffness maps. Visual assessment of tumor necrosis on subtraction images and calculation of enhancement ratios by placing ROIs over tumors on CE-T1WI was performed. TS measured with MRE showed a significant correlation with tumor enhancement and necrosis.

in vivo detection of tumor response to radiotherapy using Imaging Micro-structural Parameters Using Limited Spectrally Edited Diffusion

xiaoyu jiang¹, hua li¹, zou yue¹, junzhong xu¹, and john Gore¹

¹vanderbilt university institute of imaging science, nashville, TN, United States

The changes that occur over a cell cycle play a vital role in mediating a cell's sensitivity towards radiation therapy. Radiation exposure is expected to arrest cells at a particular cell cycle phase which improves the effectiveness of subsequent doses of radiation/chemotherapy. Cells in different phases have different sizes that can be detected by diffusion MRI with appropriate diffusion times. In this study, we evaluate the hypothesis in a rat glioma model that measurements of mean tumor cell size provides a means to quantify changes of cell phase distributions, and hence is capable of monitoring tumor response to radiotherapy.

Diffusion Weighted Imaging (DWI) is a valuable method of characterising tumour cellularity and assessing tumour response to therapy. Diffusion Kurtosis Imaging (DKI) is now being investigated outside of the brain, as the diffusional kurtosis metrics are strongly linked to cellular microstructure and heterogeneity in tissues. This work assesses tumour response to anti-angiogenic therapies as derived from DWI and DKI data in a cohort of patients with liver metastases enrolled on an early phase clinical trial. Our results demonstrate a significant cohort response to treatment of the ADC parameter, but also observed significant non-Gaussian diffusion behaviour.

Impacting cancer cells via mechanical waves: can we change cellular behaviour?

Marlies Christina Hoelzl¹, Frederic Festy², Gilbert Fruhwirth³, and Ralph Sinkus⁴

¹Biomedical Engineering, King's College London, London, United Kingdom, ²Tissue Engineering & Biophotonics, King's College London, ³Imaging Chemistry and Biology, King's College London, London, United Kingdom, ⁴Biomedical Engineering, King's College London, London, United Kingdom

90% of cancer related deaths are caused by cancer metastasis, a process where cells leave the primary tumour, disseminate and form outgrowth at the secondary metastatic site. The tumour microenvironment provides crucial signals ((bio)chemical, mechanical) to regulate tumour formation, progression, and cell spread throughout the body. Translation of mechanical forces, displacements and deformations into biochemical signals (i.e. mechanotransduction) affects their cell behaviour (adhesion, spread, survival).^{1,2} We show here that multiple treatment of tumour spheroids (solid tumour model in vitro) with focussed shear waves operating at specific frequency and amplitude results in reduced growth and reduced invasive behaviour of cancer cells.

Combining phosphatidylserine (PS)-targeting monoclonal antibodies with radiation therapy can potentially enhance treatment efficacy. Oxygenation is important in radiation therapy response and could influence future treatment design. Oxygen enhanced MRI was used to examine changes in oxygenation in orthotopic lung tumors in rats treated by radiation or radiation plus a PS-targeting antibody. Orthotopic tumors were well oxygenated and responsive to oxygen breathing challenges before and after treatment. Combination therapy appeared to be more effective in tumor control than radiation alone.

Multiparametric MRI assessment of tumor physiological changes during hypofractionated SABR

Heling Zhou¹, Zhang Zhang², Rebecca Denney¹, Jessica S Williams³, Jeni Gerberich¹, Strahinja Stojadinovic³, Debabrata Saha², John M Shelton³, and Ralph P Mason¹

¹Radiology, Univ Texas Southwestern Medical Center, Dallas, TX, United States, ²Radiation Oncology, Univ Texas Southwestern Medical Center, Dallas, TX, United States, ³Internal Medicine, Univ Texas Southwestern Medical Center, Dallas, TX, United States

Hypofractionated stereotactic body radiation therapy, a new radiation treatment scheme, may be particularly susceptible to tumor hypoxia. We applied oxygen enhanced MRI together with DCE MRI to observe tumor physiological changes induced by a radiation fraction in a human lung cancer xenograft rat model. This study showed reduced vascular oxygenation 24 hours after the first fraction of 12 Gy, as indicated by the significant decrease in T₂* compared to baseline, but no significant response in dynamic contrast enhanced MRI. DCE parametric maps revealed a multinodular structure in the tumor as confirmed by histology.

Absence of oxygen enhanced changes in T2* within head and neck cancer metastatic cervical lymph nodes is associated with local disease recurrence within 2-years following chemoradiotherapy

Harbir Singh Sidhu¹, Chiara Tudisca¹, David Price², Sola Adeleke¹, Marianthi-Vasiliki Papoutsaki¹, Martin Forster³, Ruheena Mendes⁴, Stuart Andrew Taylor¹, and Shonit Punwani¹

¹Centre for Medical Imaging, University College London, London, United Kingdom, ²Medical Physics, University College London Hospital, London, United Kingdom, ³Research Department of Oncology, University College London, London, United Kingdom, ⁴Radiotherapy Department, University College London Hospital, London, United Kingdom

Hypoxia within head and neck squamous cell cancer metastatic lymph nodes is associated with poorer outcomes following chemoradiotherapy when measured directly using polarographic probes.

The utility of non-invasive pretreatment T2* measurement in prediction of chemoradiotherapeutic response was investigated. Our data suggest, however, that nodes demonstrating sustained post-therapy complete local response based on two-year follow-up are significantly more hypoxic compared with relapsing-nodes and paradoxically demonstrate a significant increase in hypoxia on breathing 100%-oxygen.

Following further work to ascertain the mechanisms of these observed changes, the differential response to oxygen and lower baseline oxygenation in responding-nodes could be exploited in risk stratification.

Synopsis: A k_{10} parametric image maps $\text{Na}^+\text{K}^+\text{ATPase}$ activity with intra-tumor resolution. For breast tumors, the k_{10} hot spot fraction decreases after one NACT cycle if the tumor goes on to be cancer-free after NACT completion, but not if it maintains residual cancer. Also, though k_{10} hot spots are reduced after one NACT cycle, new ones appear in different *loci*. This is consistent with metabolic competition between different cancer cell populations within the tumor.

In-vivo Detection of Acute Intracellular Acidification in Glioblastoma Multiforme by AACID CEST MRI Following a Single Dose of Cariporide and Quercetin

Mohammed Albatany^{1,2}, Alex Li², Susan Meakin³, and Robert Bartha^{1,2}

¹Department of Medical Biophysics, University of Western Ontario, London, ON, Canada, ²The Centre for Functional and Metabolic Mapping, Robarts Research Institute, University of Western Ontario, London, ON, Canada, ³Department of Biochemistry, University of Western Ontario, London, ON, Canada

Identification of tumor boundaries is challenging due to the infiltrative nature of the cancer. Cariporide and quercetin are drugs approved for human use that target different pH regulatory mechanisms in cancer. The goal of the current study is to determine whether chemical exchange saturation transfer (CEST) MRI is sensitive to tumor acidification after cariporide or quercetin injection. In mice with U87 glioblastoma brain tumors, we found both drugs significantly reduced tumor pH within two hours of treatment measured by CEST MRI. The physiological change induced by cariporide or quercetin could help localize brain cancer and monitor tumor response to chemotherapy. This unique approach to cancer detection does not require injection of an imaging contrast agent.

Computer 20

DCE-MRI Assessment of Breast Cancer Response to Neoadjuvant Chemotherapy: Early Prediction of Response and Evaluation of Residual Disease

Alina Tudorica¹, Karen Y Oh¹, Kathleen A Kemmer¹, Megan L Troxell¹, Arpana Naik¹, Neda Jafarian¹, Yiyi Chen¹, Stephen YC Chui¹, Eric Goranson¹, Nicole Roy¹, Aneela Afzal¹, May Mishal¹, Megan L Holtorf¹, Charles S Springer¹, Xin Li¹, and Wei Huang¹

¹Oregon Health & Science University, Portland, OR, United States

DCE-MRI was performed on 47 breast cancer patients (49 primary tumors) before, during, and after neoadjuvant chemotherapy (NACT). DCE-MRI data were subjected to Tofts model (TM) and Shutter-Speed model (SSM) pharmacokinetic (PK) analysis. Imaging metrics and the corresponding percent changes were correlated with binary pathologic complete response (pCR) and non-pCR endpoints, as well as residual cancer burden (RCB) index values. By NACT midpoint, several DCE-MRI PK parameters and percent changes are good early predictors of pCR vs. non-pCR, while tumor size is a poor predictor. Both PK parameters and tumor size after NACT completion are good markers of RCB. TM and SSM parameters perform equally well for prediction of NACT response and evaluation of RCB.

Near infrared photoimmunotherapy for lung cancer in a transgenic mouse model evaluated by MRI

Yuko Nakamura^{1,2}, Marcelino Bernardo¹, Zoe Weaver Ohler³, Tadanobu Nagaya¹, Shuhei Okuyama¹, Fusa Ogata¹, Peter L. Choyke¹, and Hisataka Kobayashi¹

¹National Cancer Institute, Bethesda, MD, United States, ²Diagnostic Radiology, Hiroshima University, Hiroshima, Japan, ³Frederick National Laboratory for Cancer Research

Near infrared photoimmunotherapy (NIR-PIT) is a new cancer treatment that combines the specificity of antibodies for targeting tumors with the toxicity induced by photoabsorbers after irradiation with NIR light. The purpose of this study was to determine whether MRI can monitor the therapeutic effect of NIR-PIT in spontaneously occurring lung cancers that express epidermal growth factor receptor. Tumor volume ratio was inhibited significantly in the NIR-PIT group compared with control group. Thus, MRI can be a useful imaging modality for monitoring the therapeutic effects of NIR-PIT for cancer.

- Soft tissue sarcoma DCE-MRI data collected at baseline and after one chemotherapy cycle were shared among nine centers and individual arterial input functions (AIFs) were quantified with center-specific methods. Pharmacokinetic (PK) modeling of the data was performed with these AIFs and the Tofts model. Considerable variations in estimated PK parameters and the corresponding percent changes were observed due to AIF variations. k_{ep} is less susceptible to AIF variation than K^{trans} and may be a more robust imaging biomarker of microvasculature. k_{ep} percent change correlates in a uniformly negative relationship with necrosis percentage of resection specimen across all individually measured AIFs.

- 4376 Computer 26 [Predicting MGMT expression levels in glioma patients using multi-inversion-time PASL](#)
 Yuchao Liang¹, Yinyan Wang¹, Tianyi Qian², Josef Pfeuffer³, Shaowu Li⁴, Tao Jiang^{1,5}, and Lei Wang¹
¹Neurosurgery, Beijing Tiantan Hospital, Beijing, People's Republic of China, ²MR Collaborations NE Asia, Siemens Healthcare, Beijing, People's Republic of China, ³Application Development, Siemens Healthcare, Erlangen, Germany, ⁴Neuroimaging center, Beijing Neurosurgical Institute, Beijing, People's Republic of China, ⁵Neurosurgery, Beijing Neurosurgical Institute, Beijing, People's Republic of China

To evaluate the differences in cerebral blood flow between glioma patients with high MGMT expression and those with low MGMT expression, we retrospectively compared cerebral blood flow in pre-operative MR images acquired using multi-inversion-time PASL from glioma patients with histopathologically confirmed high MGMT expression and those with histopathologically confirmed low MGMT expression. The results demonstrate that MGMT expression status significantly correlates with both quantitative CBF and relative CBF.

- 4377 Computer 27 [Utilizing correlations between Ktrns and plasma volume fraction estimates improves extended Kety modelling of DCE-MRI data](#)
Matthew R Orton¹, Mihaela Rata¹, David J Collins¹, James A d'Arcy¹, and Martin O Leach¹
¹CRUK Cancer Imaging Centre, Division of Radiotherapy and Imaging, Institute of Cancer Research, Sutton, United Kingdom

The extended Kety model is widely used for deriving quantitative perfusion and vascularity measures from DCE-MRI. In practice the signal contribution from the plasma space can be low compared to the signal-to-noise ratio (SNR) of the data which leads to cases where K_{trans} is non-zero (indicating delivery of contrast to the tissues), but where the plasma volume fraction is estimated as zero: a logical contradiction. This work describes a model and fitting methodology to overcome this that makes use of a relationship between K_{trans} and the plasma volume fraction to ensure both are positive or both are zero.

$R2^*$ relaxation affects pharmacokinetic analysis of DCE-MRI at high field strength

Eugene Kim¹, Jana Kim¹, and Siver Andreas Moestue¹

¹MR Cancer Group, Department of Circulation and Medical Imaging, NTNU Norwegian University of Science and Technology, Trondheim, Norway

In DCE-MRI, the effect of the $r2^*$ relaxivity of gadolinium-based contrast agents is often assumed to be negligible. Here, the validity of this assumption at 7T was tested. DCE-MRI was performed on two preclinical cancer models using a spoiled multiple gradient-echo acquisition, which enabled correction for transverse relaxation. Not accounting for $R2^*$ resulted in underestimation of the Tofts pharmacokinetic parameters, with K^{trans} being the most affected and v_p the least. Simulations showed that the $R2^*$ effect can be significant even at 3T in highly perfused regions but can be mitigated by decreasing TE and TR or increasing the flip angle.

Arterial Input Function Selection in DSC-MRI of Brain Tumors Using Differential Evaluation Clustering Method

Hossein Rahim Zadeh¹, Anahita Fathi Kazerooni^{1,2}, Mohammad Reza Deevband³, and Hamidreza Saligheh Rad¹

¹Quantitative MR Imaging and Spectroscopy Group, Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, Iran, ²Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, Iran, ³Shahid Beheshti University of Medical Sciences, Tehran, Iran

Proper arterial input function (AIF) selection is a critical step for accurate quantification of dynamic susceptibility contrast enhanced (DSC) MRI in brain tumor patients. In this study, we have employed differential evaluation (DE) clustering method on processed perfusion images for accurate AIF selection. The procedure consists of two main steps: preprocessing for eliminating non-arterial curves including tissue, noisy and those contaminated with partial volume effects; and AIF selection using DE clustering method. The performance of this clustering method was compared to K-means and Hierarchical Clustering techniques and the results show the superiority of the proposed approach for accurate AIF selection.

4382

Model-based and Non-model-based Perfusion-related Predictors of Response to Chemotherapy in Intrahepatic Cholangiocarcinoma

Kristen Zakian¹, Aditi Iyer¹, Aditya Apte¹, Taryn Boucher², William Jarnagin³, Nancy Kemeny⁴, and Richard Do²

¹Medical Physics, Memorial Sloan-Kettering Cancer Center, New York, NY, United States, ²Radiology, Memorial Sloan-Kettering Cancer Center, New York, NY, United States, ³Surgery, Memorial Sloan-Kettering Cancer Center, New York, NY, United States, ⁴Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY, United States

Hepatic arterial infusion of floxuridine has shown benefit in intrahepatic cholangiocarcinoma. Due to the complexity and expense of this treatment, a pre-treatment or early biomarker of efficacy would be advantageous. We employed non-model-based (NMB) analysis to maximize information from breath-motion degraded DCE-MRI in 24 patients. Model-based and NMB parameters were compared to RECIST response. The kurtosis value of pre-treatment time-to-half-maximum correlated with response, as did 1 month changes in perfusion parameters (K^{trans} and signal at half maximum). NMB analysis resulted in fewer voxels being discarded due to motion and thus may be more representative of tumor physiology while not requiring modeling.

4384

Computer 34

Optimization of acquisition and modelling parameters for accurate and precise estimation of tumor vascular permeability using modified K-CNR
Thomas S.C. Ng¹, Ravi T. Seethamraju², and Ritu R. Gill¹

¹Radiology, Brigham and Women's Hospital, Boston, MA, United States, ²Siemens Healthcare USA

Adoption of quantitative clinical DCE-MRI remains limited given the challenges in accurate and precise estimation of kinetic parameters. Simulations are being increasingly used to guide protocol optimization¹, but the relative effects of altering protocol variables are seldom considered. We used a modified K-CNR metric to quantify tumor Ktrams estimation. K-CNR provided a simple way to compare how input variables affect Ktrams output. The extended Toft's model was shown to be robust for tumor relevant Ktrams. Lengthening baseline time can improve Ktrams estimation. Care must be taken when using nested model analysis; wrong model convergence can occur with non-optimized acquisition variables.

Robust and Efficient Perfusion Parameter Estimation for DCE-MRI of the Prostate Utilizing the Variable Projection (VARPRO) Method

Soudabeh Kargar¹, Eric Stinson², Eric Borisch², Adam Froemming², Akira Kawashima³, Lance Mynderse⁴, Joshua Trzasko², and Stephen Riederer^{1,2}

¹Biomedical Engineering and Physiology, Mayo Graduate School, Rochester, MN, United States, ²Radiology, Mayo Clinic, Rochester, MN, United States, ³Radiology, Mayo Clinic, Scottsdale, AZ, United States, ⁴Urology, Mayo Clinic, Rochester, MN, United States

Dynamic contrast enhanced-MRI is essential for assessment of tissue microvasculature, and thus improved methods of parameter estimation for evaluation of tissue perfusion can be valuable. This work demonstrates how application of Variable Projection (VP) in perfusion analysis increases the robustness and computation efficiency compared to the conventional Levenberg-Marquardt (LM) method. A numeric simulation is used to validate the perfusion estimation and evaluate the robustness with respect to noise. The computation speed of VP is shown to be improved about 5x faster compared to LM method. VP-based perfusion analysis is demonstrated in eight patients with known prostate cancer.

4386

Computer 36

Weighted Total Least Squares for Parameter Estimation with the Two Compartment Exchange Model

Anders Garpebring¹ and Tommy Löfstedt¹

¹Radiation Sciences, Umeå University, Umeå, Sweden

When using linear least squares to estimate pharmacokinetic model parameters in dynamic contrast-enhanced MRI there is a risk of introducing bias due to noise correlations. By using a weighted total least squares (WTLS) method instead, these correlations are taken into account. The results of this study shows that the WTLS method is able to reduce the bias considerably compared to the linear least squares method for the two compartment exchange model, however, at the expense of increased computational time.

Computer 37

Diffusion-weighted MRI of rectal cancer: baseline tumour perfusion fraction predicts chemoradiotherapy response and survival

Kine Mari Bakke^{1,2}, Knut Håkon Hole³, Svein Dueland⁴, Krystyna Grøholt⁵, Kjersti Flatmark^{6,7,8}, Anne Hansen Ree^{1,8}, Therese Seierstad³, and Kathrine Røe Redalen¹

¹Department of Oncology, Akershus University Hospital, Lørenskog, Norway, ²Institute of physics, University of Oslo, Oslo, Norway, ³Department of Radiology and Nuclear Medicine, Oslo University Hospital, ⁴Department of Oncology, Oslo University Hospital, ⁵Department of Pathology, Oslo University Hospital, ⁶Department of Tumor Biology, Oslo University Hospital, ⁷Department of Gastroenterological Surgery, Oslo University Hospital, ⁸Institute of Clinical Medicine, University of Oslo

More accurate diagnostics for prediction of treatment responses in locally advanced rectal cancer is warranted. We employed a simplified approach to the intravoxel incoherent motion imaging method to estimate the tumour perfusion fraction from diffusion-weighted MRI. The perfusion fraction was predictive of the histologic tumour response after chemoradiotherapy ($p = 0.02$), and in combination with tumour volume this parameter was also predictive of five-year progression-free survival of the patients ($p = 0.002$). This simplified approach does not require substantial extra scan time in a routine diagnostic scanning, and may offer a clinically feasible approach to stratifying patients to individualised treatment.

¹Department of Radiotherapy, UMC Utrecht, Utrecht, Netherlands, ²Department of Radiology, UMC Utrecht, Utrecht, Netherlands, ³Department of Radiation Physics, MD Anderson Cancer Center, TX, United States

DWI shows high contrast between tumor and surrounding tissue, which shows potential for target volume delineation in head-and-neck radiotherapy treatment planning. In this study we assess the performance of a diffusion weighted fast spin echo sequence (DW-SPLICE) for target delineation in terms of interobserver agreement and spatial concordance with PET. Fifteen patients underwent both PET and DW-SPLICE. PET was segmented using a Gaussian mixture model, DW-SPLICE was delineated by 3 observers. Target volume delineation using DWI is feasible in head-and-neck radiotherapy. Using an optimized DWI sequence, target volumes could be defined with good interobserver agreement and large similarity with PET.

Distortion-Free Diffusion MRI using an MRI-Guided Tri-Cobalt 60 Radiotherapy System: Sequence Validation and Preliminary Clinical Experience

Yu Gao^{1,2}, Minsong Cao^{2,3}, Tania Kaprealian³, Mitchell Kamrava³, Michael Wang³, John Neylon³, Daniel Low^{2,3}, Yingli Yang^{2,3}, and Peng Hu^{1,2}

¹Radiology, University of California, Los Angeles, Los Angeles, CA, United States, ²Physics and Biology in Medicine IDP, University of California, Los Angeles, Los Angeles, CA, United States, ³Radiation Oncology, University of California, Los Angeles, Los Angeles, CA, United States

Limited resolution, severe distortion, and inaccurate quantification in low SNR scenarios associated with the conventional DW-ssEPI are problematic for adaptive radiotherapy based on tumor response. In this study, we sought to develop a reliable, accurate and distortion-free diffusion sequence that is practicable for longitudinal assessment of tumor response using an MRI-guided radiotherapy system. Quantitative phantom studies validated the superiority of the proposed technique over standard DW-ssEPI in terms of geometric fidelity and ADC accuracy. Excellent ADC reproducibility makes it a promising candidate for tumor response monitoring. Preliminary patient study demonstrated its feasibility to be used for tumor response assessment.

Proton Magnetic Resonance Spectroscopy of the Lipid Metabolic Response of a Murine Tumor Model to Radiation Therapy

Anthony G. Tessier¹, Atiyah Yahya^{1,2}, Matthew Larocque^{1,2}, B. Gino Fallone^{1,2}, and Alasdair Syme^{3,4}

¹Medical Physics, Cross Cancer Institute, Edmonton, AB, Canada, ²Oncology, University of Alberta, Edmonton, AB, Canada, ³Radiation Oncology, Dalhousie University, Halifax, NS, Canada, ⁴Medical Physics, QEII Health Sciences Centre, Nova Scotia Health Authority, Halifax, NS, Canada

The temporal dependence of the lipid metabolic response to single fraction radiation therapy of human glioblastoma multiforme xenografts in NIH III nude mice was assessed with *in vivo* ¹H magnetic resonance spectroscopy (MRS) on a 9.4T magnetic resonance system. Lipid MRS can measure fat polyunsaturation, and therapeutic response can be monitored. The methylene:methyl peak ratio (CH₂/CH₃) can assess drug treatment and disease progression. Herein, lipid parameters and their response to radiotherapy in tumors are studied, including methyl, lactate + methylene, diallylic, and allylic protons, protons in α position to the carbonyl group, CH₂/CH₃, and mean polyunsaturation.

Longitudinal diffusion MRI for treatment assessment of sarcoma patients with pre-operative radiation therapy

Yingli Yang¹, Minsong Cao¹, Yu Gao², Mitchell Kamrava¹, Anusha Kalbasi¹, Nzhde Agazaryan¹, James Lamb¹, Ke Sheng¹, Daniel Low¹, and Peng Hu²

¹Radiation Oncology, UCLA, Los Angeles, CA, United States, ²Radiology, UCLA, Los Angeles, CA, United States

Diffusion weighted MRI (DWI) is promising for early prediction of tumor response to radiation therapy. We report our results of using longitudinal DWI approach performed on ViewRay system for predicting the response of sarcoma patient to pre-op RT. Six sarcoma patients were recruited in this study. Each patient subsequently underwent surgery. The tumor necrosis score was then used to compare to the ADC values to assess the predictive value of longitudinal DWI. Each patient successfully underwent 3–5 diffusion MRI scans. Based on the data from 6 patients, our longitudinal changes in tumor ADC matched well with pathology necrosis results.

4394 Computer 44 Integrated volumetric diffusion-weighted MR imaging and HPV genotyping in outcome prediction for stage IB-IV cervical cancer patients following chemoradiation therapy

Gigin Lin¹, Chyong-Huey Lai¹, and Yu-Chun Lin¹

¹Medical Imaging and Intervention, Chang Gung Memorial Hospital, Linkou, Taiwan

We evaluated the values of integration of pretreatment volumetric ADC analysis with human papillomavirus (HPV) genotyping in prediction of survival and recurrence for women with locally advanced cervical cancer in 82 women following concurrent chemoradiation therapy (CCRT). Independent poor prognostic indicators for OS and DFS by stepwise multivariate analysis, i.e., lower ADC10, advanced T or M stage and high-risk HPV status were composed to generate a novel outcome-predicting model, in which death was found in all the high-risk group patients while none of the low-risk group died or recurred during the follow up.

4395 Computer 45 Longitudinal assessment of tumor volume and apparent diffusion coefficient in patients on active surveillance: a good way of monitoring disease progression?

Veronica A Morgan¹, Christopher Parker², and Nandita M deSouza¹

¹CRUK Imaging Centre, The Institute of Cancer Research, Surrey, United Kingdom, ²Academic Urology Unit, The Royal Marsden Hospital NHS Foundation Trust, Sutton, United Kingdom

Tumor growth on T2-W MRI in 151 men with low-risk prostate cancer managed by active surveillance was related to tumor apparent diffusion coefficient (ADC). Volume increases greater than the 95% upper Limits of Agreement of reproducibility (~60%, n=20) were seen in 52 (34.4%) men. ADC was more reproducible (~5% variability). Baseline ADC values did not differ between those with and without measurable growth (p=0.06) but change in ADC did (-6.8±12.3% for those with measurable growth vs. 0.23±10.1% for those without, p=0.0005). A 5.6% reduction in ADC with time indicated a measurable increase in tumor volume (specificity 77.0%, sensitivity 54.9%, AUC=0.67).

4396 Computer 46 Textural Analysis based Segmentation of Bone tumours using Diffusion Weighted MR Image

Amit Mehndiratta^{1,2}, Esha Baidya Kayal³, Rishabh Gupta³, Abhimanyu Sahai³, Jayendra Tiru Alampally⁴, Sameer Bakhshi⁵, Raju Sharma⁴, and Devasenathipathy Kandasamy⁴

¹Centre for Biomedical Engineering, Indian Institute of Technology Delhi, New Delhi, India, ²Department of Biomedical Engineering, All India Institute of Medicine, New Delhi, India, ³Centre for Biomedical Engineering, Indian Institute of Technology Delhi, ⁴Department of Radio Diagnosis, All India Institute of Medical Sciences, ⁵Institute-Rotary Cancer Hospital, All India Institute of Medical Sciences

Diffusion weighted imaging (DWI) plays a crucial role in diagnosis and prognosis of cancerous diseases. Proper demarcation of tumour on DWI is therefore necessary for qualitative assessment as well as quantitative image analysis like ADC or IVIM. Manual demarcation of tumour on each DWI slice is time consuming, prone to error and hard to reproduce. Automated and semi-automated algorithms were implemented and tested to segment bone tumours specifically on DWI. Experimental results reveal that semi-automated Active-Contours performed tumor segmentation better than other methods with acceptable levels of accuracy with considerable less time and manual effort.

4397 Computer 47 MR imaging in the prediction of aggressive histological features in papillary thyroid carcinoma

Bin Song¹ and Hao Wang¹

¹Radiology, Central Hospital of Minhang District, Fudan University, Shanghai, People's Republic of China

Purpose To investigate the value of magnetic resonance imaging (MRI) features for prediction of tumor aggressiveness in papillary thyroid cancer (PTC). Method A consecutive series of 119 lesions with PTC were preoperatively evaluated by MR imaging. A multivariate analysis was performed to predict tumor aggressiveness by 18 independent variables. Results Multivariate analysis demonstrated that lesion size classification and tumor margin on delayed contrast-enhanced images were the independent predictors of high aggressive PTC. Conclusion Lesion size classification and tumor margin on delayed contrast-enhanced images can be used preoperatively to estimate the risk of high aggressive of PTC.

4398 Computer 48 Optimization of b-values in iShim diffusion-weighted MR imaging of the thyroid gland: to improve the visualization of malignant thyroid nodules and the accuracy in differentiating malignant from benign thyroid nodules

Qingjun Wang¹, Qinglei Shi², Tianyi Qian³, Alto Stemmer⁴, and Yong Guo¹

¹Department of Radiology, Chinese Navy General Hospital, Beijing, People's Republic of China, ²Scientific Marketing, Siemens Healthcare, People's Republic of China, ³MR Collaboration, HC NEA MR COL, Siemens Healthcare, People's Republic of China, ⁴MR Application Predevelopment, Siemens Healthcare GmbH

To investigate the optimal b-values of diffusion-weighted imaging (DWI), a prototype sequence with integrated slice-specific shimming (iShim) was applied for visualizing thyroid malignant nodules and making accurate differentiation between benign and malignant nodules. DWI images were acquired with five b-values including 0, 800, 1000, 2000 and 3000 sec/mm². The results show that the iShim-DWI with b-value of 800 s/mm² can present the clearest delineation of malignant thyroid nodules and that the images with b-value of 3000 s/mm² had the best performances in differentiating malignant from benign thyroid nodules.

From medulla to lower cervical levels, a multi-parametric quantitative MR investigation dedicated to the diffuse alterations of the spinal cord at 7T: first insights into Amyotrophic Lateral Sclerosis

Aurélien Massire^{1,2,3}, Henitsoa Rasoanandrianina^{1,2,3}, Thorsten Feiweier⁴, Manuel Taso^{1,2,3}, Aude-Marie Grapperon⁵, Shahram Attarian⁵, Maxime Guye^{1,2}, Jean-Philippe Ranjeva^{1,2,3}, Annie Verschueren⁵, and Virginie Callot^{1,2,3}

¹Aix-Marseille Université, CNRS, CRMBM UMR 7339, Marseille, France, Marseille, France, ²AP-HM, Hôpital de la Timone, Pôle d'imagerie médicale, CEMEREM, Marseille, France, Marseille, France, ³iLab-Spine - Laboratoire international associé - Imagerie et Biomécanique du rachis, France/Canada, Marseille, France, ⁴Siemens Healthcare GmbH, Erlangen, Germany, ⁵Service de Neurologie et Maladies neuromusculaires, Hôpital de La Timone, AP-HM, Marseille, France

Amyotrophic lateral sclerosis (ALS) may benefit from unique contrasts and high-spatial resolutions provided by ultra-high field brain MRI. This also stands for spinal cord; nevertheless spinal cord imaging at 7T has lagged considerably behind brain investigations until recently. In this work, we propose a multi-parametric quantitative MR imaging protocol (T_1 , T_2^* , DTI, CSA), in an acquisition time compatible with clinical research (50min), to comprehensively investigate spinal cord diffuse alterations in neurodegenerative diseases such as ALS. With imaging along the whole cervical cord and medulla, these multi-parametric acquisitions have the potential to provide new insights for the study of ALS.

Current diagnostic tools fail to accurately assess the condition of the eye muscles and orbital fat in ocular diseases. We have developed a high-resolution 7 Tesla quantitative MRI-protocol of the eye and evaluated its clinical value for Graves' orbitopathy and myasthenia gravis. The scan protocol proved to be robust against eye-motion and extra-ocular muscles were easily segmented from the orbital fat. Patient data showed elevated muscle fat fractions for both conditions compared to healthy subjects. Since the method quantifies the condition of the tissues, which otherwise can only be assess via an invasive biopsy, it potentially is an efficient technique to assess treatment response.

A Feasibility Study on Bilateral Monopole Antenna with Two Common Grounds for 7T MRI

Han-Joong Kim¹, Hyunwoo Song¹, Sang-Doc Han¹, Phil Heo¹, Donghyuk Kim², Yeonjin Choi³, and Kyoung-Nam Kim³

¹Department of Health Sciences and Technology, Gachon University, Incheon, Korea, Republic of, ²Neuroscience Research Institute, Gachon University, Incheon, Korea, Republic of, ³Department of Biomedical engineering, Gachon University, Incheon, Korea, Republic of

In this study, a bilateral monopole antenna was proposed to have ring element of existing ring-monopole as common ground and to consist of two interlocking monopole antennas along z-axis to improve lopsided $|B_1|$ field toward the ground plate. Geometry of the proposed bilateral monopole antenna was optimized with EM simulation then optimized antenna was compared with a transceiver array coil and a birdcage coil for quality verification. Even with worse power consumption, the proposed bilateral monopole antenna can be an alternative for existing RF coils such as transceiver array coil and birdcage coil due to its improved $|B_1|$ field uniformity.

Newly Designed Miniaturized Patch Antenna with High Dielectric Material Plugs

Gangchea Lee¹, Navid Pourramzan Gandji², Seokwon Jung³, Elena Semouchkina², Michael Lanagan⁴, and Thomas Neuberger^{1,5}

¹Bio Engineering, Pennsylvania State University, University Park, PA, United States, ²Electrical and Computer Engineering, Michigan Tech University, Houghton, MI, United States, ³Mechanical and Nuclear Engineering, Pennsylvania State University, University Park, PA, United States, ⁴Engineering Science and Mechanics, Pennsylvania State University, University Park, PA, United States, ⁵Huck Institutes of the Life Sciences, Pennsylvania State University, University Park, PA, United States

High performance Radio Frequency resonators (RF resonators) produce strong and homogeneous magnetic fields. Due to their large sizes, patch antennas have hardly been considered to be used as RF resonators in Magnetic Resonance Imaging (MRI), especially at high fields. In this work, a newly developed miniaturized patch antenna with high dielectric material plugs was designed, simulated, built and tested at 14.1 T. The simulated and experimental magnetic fields were compared to confirm the performance of the fabricated patch antenna as a RF resonator for MRI.

General advantages of ultra-high-field MRI at 7 T in cerebral arteriovenous malformations (AVM) imaging have been shown recently. This prospective clinical study (10 adult patients) aims to evaluate signal characteristics of AVM feeders, nidus and drainage using 7 T MRI (TOF, MPRAGE, SWI). AVM feeders, nidus and drainage were evaluated by 2 raters. Additionally, AVMs were segmented manually and signal intensity histograms were calculated for the extracted feeders, nidus and drainage, respectively. As previously shown, 7 T MRI has excellent imaging results regarding vessel delineation in AVMs. However, identification of the AVM architecture remains challenging due to signal heterogeneity.

4412

Microstrip Resonator for High Field MRI with Capacitor-Segmented Strip and Ground Plane

Vitaliy Zhurbenko¹, Vincent Boer², and Esben Thade Petersen^{1,2}

¹Technical Univ. of Denmark, Kgs. Lyngby, Denmark, ²Danish Research Centre for Magnetic Resonance, Centre for Functional and Diagnostic Imaging and Research, Copenhagen University Hospital, Hvidovre, Denmark

High field MRI coils are often based on transmission line resonators. Due to relatively short wavelength of RF fields, such coils produce uneven field patterns. Here we show, that it is possible to manipulate magnetic field patterns of microstrip resonators in both planes (sagittal and transverse) segmenting stripe and ground plane of the resonator with series capacitors. The design equations for capacitors providing symmetric current distribution are derived. The performance of two types of segmented resonators are investigated experimentally. To authors' knowledge, a microstrip resonator, where both, strip and ground plane are capacitor-segmented, is shown here for the first time.

Monopole Antenna Array for UHF Magnetic Resonance Imaging

A S M Zahid Kausar¹, David Reutens¹, Ewald Weber², and Viktor Vegh¹

¹Center for Advanced Imaging, University of Queensland, Brisbane, Australia, ²School of Information Technology and Electrical Engineering, University of Queensland, Brisbane, Australia

Birdcage coils have a number of limitations, especially at ultra-high field. Monopole antenna arrays have been proposed as an alternative to birdcage coils, as the design is simpler and they do not use capacitors. We evaluated the potential of using monopole arrays for 3T and 7T MRI brain scans. To be able to benchmark performance, we compared the field produced by the monopole array with the field produced by the birdcage coil. We show that monopole arrays can potentially achieve better field homogeneity and sensitivity than the birdcage coil. We fabricated a monopole array and demonstrated decoupling between individual monopoles.

Computer 93

A method to experimentally assess "coil loss" of a dipole antenna for Ultra-High-Field (UHF) MRI

Gang Chen^{1,2}, Christopher M. Collins^{1,2}, Daniel K. Sodickson^{1,2}, and Graham C. Wiggins¹

¹Center for Advanced Imaging Innovation and Research (CAI2R), New York University School of Medicine, New York, NY, United States, ²The Sackler Institute of Graduate Biomedical Science, New York University School of Medicine, New York, NY, United States

At clinical field strengths, the contribution of coil noise is often characterized by the Q-ratio, the ratio of the loaded Q and unloaded Q. Because of the inconsistent contribution of radiation loss and frequency drift in unloaded and loaded cases, it is difficult to characterize the body noise dominance of a dipole antenna by conventional Q ratio at 7T. Here we propose a new approach using a measure of Q when a dipole antenna is well shielded. The shielded/loaded Q ratio estimates the relative noise contribution from coil loss, similar to unloaded/loaded Q ratio for surface coil at low frequencies.

A new RF coil for foot and ankle imaging at 7T MRI

Tales Roberto de Souza Santini¹, Junghwan Kim¹, Sossena Wood¹, Narayanan Krishnamurthy¹, Shailesh Raval¹, and Tamer Ibrahim¹

¹University of Pittsburgh, Pittsburgh, PA, United States

7T Foot and ankle has been previously explored¹. A four-channel Tic-Tac-Toe (TTT) transmit-only (Tx-only) array^{2,3} and a four-channel receive-only array were developed and combined to demonstrate the feasibility of high signal-to-noise ratio (SNR) foot and ankle imaging at 7T MRI. The experimental measurements of magnetic field distribution responsible for excitation (B₁₊) is in agreement with the finite-difference time-domain (FDTD) simulations and the SAR is within the FDA safety limits for the entire lower leg and foot (peak SAR ~ 7W/Kg/10g of tissue, average SAR ~ 1W/Kg/10g of tissue per continuous average field B₁₊ = 1.97uT). In-vivo proton density TSE and T2DESS images were acquired.

Improving Image Quality by Adjusting Relative Phases of Channels with a Two-element Rotating Coil Array at 9.4T

Mingyan Li¹, Ewald Weber¹, Jin Jin¹, Yasvir Tesiram², Thimo Hugger³, Simon Stark³, Feng Liu¹, Sven Junge³, and Stuart Crozier¹

¹School of Information Technology and Electrical Engineering, The University of Queensland, Brisbane, Australia, ²Centre for Advanced Imaging, The University of Queensland, Brisbane, Australia, ³Bruker BioSpin MRI GmbH, Ettlingen, Germany

This work investigates the feasibility of incorporating an additional RF element to the rotating RF coil (RRFC) to improve imaging performance. The transmit profiles of the two-element rotating coil array were optimised by adjusting the interference patterns formed by two channels with varied relative phase. Combined with the previously developed rotating imaging scheme, an optimal relative phase was determined to produce an image uniformity of 93%.

EKG-based detection of deep brain stimulation (DBS) for fMRI studies

Eric Fiveland¹, Julia Prusik², Renee Linton³, Jeffrey Ashe¹, Julie Pilitsis², and Ileana Hancu¹

¹GE Global Research Center, Niskayuna, NY, United States, ²Albany Medical College, Albany, NY, United States, ³Medtronic, Minneapolis, MN, United States

A detector for measuring and predicting the on/off state of cycling deep brain stimulation (DBS) was developed and tested in 6 patients. 3-electrode EKG measurements, amplified by a commercial bio-amplifier, were used as input for a custom electronics box (e-box). The e-box transformed the DBS waveforms into transistor-transistor logic (TTL) pulses and recorded their timing. Following locking to each patient's individual waveform, the e-box was shown to predict stimulation onset with an average absolute error of 112ms, 30 minutes after disconnecting from the patients. Using this detector, stimulation can be accurately synchronized to fMRI acquisitions.

Fast 3D Design of High-Permittivity Pads for Dielectric Shimming using Model Order Reduction and Nonlinear Optimization

Jeroen van Gemert¹, Wyger Brink², Andrew Webb², and Rob Remis¹

¹Circuits and Systems, Delft University of Technology, Delft, Netherlands, ²Radiology, Leiden University Medical Center, Leiden, Netherlands

High-permittivity pads can be used to improve B₁₊ homogeneity and intensity in neuroimaging and body applications. Normally, finding the "optimal" pad for a specific region of interest involves evaluating many different pad designs using electromagnetic simulations, which is a very time-consuming approach taking hours to days of computation time. We propose a nonlinear optimization method based on model order reduction that allows us to design high-permittivity pads in less than 30 seconds.

4425

Computer 51

Improved local sensitivity in magnetic resonance spectroscopy at 3 T using a new flexible and compact metasurface

Rita Schmidt¹, Assaf Tal², and Andrew Webb¹

¹Radiology, Leiden University Medical Center, Leiden, Netherlands, ²Chemical Physics, Weizmann Institute of Science, Rehovot, Israel

Magnetic resonance spectroscopy is a powerful technique for in-vivo measurement of metabolites, however its sensitivity is limited due to very low concentration of the metabolites. This is especially valid for studies of neurotransmitters such as glutamate and GABA. In this study, a new hybrid metasurface comprising of conducting strips and agar-gel was designed to improve MR sensitivity at 3T. The metasurface forms a compact and flexible pad which is placed in the vicinity of the region of interest. The measurements focused on MRS acquisitions including PRESS and MEGA-PRESS, showing an improvement in SNR of a factor of 1.75, 2 cm from the pad.

[A Practical Imaging Scheme for a Rotating RF Coil \(RRFC\) at 9.4T by Applying Dynamic Sensitivity Averaging](#)

Mingyan Li¹, Jin Jin¹, Ewald Weber¹, Yasvir Tesiram², Thimo Hugger³, Simon Stark³, Sven Junge³, Feng Liu¹, and Stuart Crozier¹

¹School of Information Technology and Electrical Engineering, The University of Queensland, Brisbane, Australia, ²Centre for Advanced Imaging, The University of Queensland, Brisbane, Australia, ³Bruker BioSpin MRI GmbH, Ettlingen, Germany

Precise image recovery for the rotating coil requires sensitivity estimation and iterative algorithm to remove motion artifact, but inaccurate sensitivity estimation can affect image reconstruction accuracy. Previously we developed a radial sampling scheme for the RRFC which avoids sensitivity mapping procedures by manipulating oversampled central k-space data. However, the overall reconstruction inaccuracy results from relatively sparse sampled outer k-space still remained. As a more robust and preferred imaging scheme in routine MRI scans, the Cartesian trajectory will be employed to develop an imaging scheme for the RRFC to overcome the abovementioned limitations and further reduce motion artifact.

[WiFi-enabled RF Coil for Simultaneous MR Image Acquisition and Wireless Communication](#)

Dean Darnell¹, Jonathan Cuthbertson¹, Yixin Ma¹, Naomi Morales-Medina¹, Sebastian Luce¹, Allen W Song¹, and Trong-Kha Truong¹

¹Brain Imaging and Analysis Center, Duke University, Durham, NC, United States

Implementation of wireless communications in an MRI scanner will reduce the complexity of the scanner by decreasing the number of wired connections and connectors. To enable wireless communication in the scanner, a new RF coil design is proposed which allows RF currents at the Larmor and wireless data frequencies to flow on the same coil element, thus enabling simultaneous MRI image acquisition and wireless data transfer with the same coil.

4431

Computer 57

[Battery-Powered Integrated Parallel Reception, Excitation, and Shimming \(iPRES\) Head Coil Array for Plug-and-Play Localized B₀ Shimming](#)

Dean Darnell¹, Devin Willey¹, Sebastian Luce¹, Allen W Song¹, and Trong-Kha Truong¹

¹Brain Imaging and Analysis Center, Duke University, Durham, NC, United States

Integrated parallel reception, excitation, and shimming (iPRES) coil arrays enable RF excitation/reception and localized B_0 shimming with a single coil array, but so far use an external DC power supply and require a B_0 map and a shim optimization for each subject, which takes additional time. Here, we propose a novel iPRES head coil array powered by an on-board MR-compatible battery that delivers fixed DC currents optimized in advance to shim an average subject's brain. This stand-alone, plug-and-play system does not require any subject-specific shim optimization, thus enabling a wider adoption of iPRES in clinical applications.

4432

Computer 58

An evaluation of RF coil materials for $^1\text{H}/^{31}\text{P}$ for use in a hybrid MR-PET scanner at 3T
Chang-Hoon Choi¹, Lutz Tellmann¹, Jörg Felder¹, Christoph Lerche¹, and N. Jon Shah^{1,2}

¹Institute of Neuroscience and Medicine-4, Forschungszentrum Juelich, Juelich, Germany, ²Faculty of Medicine, Department of Neurology, JARA, RWTH Aachen University, Aachen, Germany

In a simultaneous MR-PET experiment, an RF resonator for MRI is placed inside the field-of-view of the PET scanner. Attenuation caused by RF coil components can cause severe artefacts in PET images if not adequately corrected. Although it may be possible to minimise subject-specific attenuation and scatter effects, correcting those due to the RF coil is still a challenging task. In this work, we have designed and constructed a number of RF coils constructed utilising a variety of copper conductors and evaluated their characteristics from the MR and PET points of view.

Tunable Electropermanent System for Magnetic Resonance Imaging and Magnetic Particle Propulsion

Alek Nacev¹, Ryan Hilaman¹, Sahar Jafari^{1,2}, Sagar Chowdhury¹, Lamar Mair¹, Pavel Stepanov¹, Dhruv Patel¹, and Irving Weinberg¹

¹Weinberg Medical Physics, Inc., North Bethesda, MD, United States, ²Biomedical Engineering, George Mason University, VA, United States

Directing magnetic nanoparticles to sites within biological tissues requires both strong magnetic field gradients and accurate images of the particles and underlying anatomy. Most modern MR imaging systems require always-on magnetic field sources such as permanent magnets or superconducting coils. These field sources limit the ability to control magnetic particles within the imaging volume. Due to these field sources having a high strength always-on magnetic field, there are additional safety concerns when attempting to integrate these sources into an intraoperative arena. We built a new magnetic field source design that is capable of adjusting its magnetic field strength while retaining a low power usage to improve portability.

4435

Computer 62

Low-attenuation RF surface coils for linac-MR hybrids: compromise between radiation dose to the skin and SNR

Radim Barta¹, Andrei Ghila¹, Satyapal Rathee^{1,2}, B Gino Fallone^{1,2}, and Nicola De Zanche^{1,2}

¹Oncology, University of Alberta, Edmonton, AB, Canada, ²Medical Physics, Cross Cancer Institute, Edmonton, AB, Canada

Aluminum and copper conductors are compared for constructing radiologically transparent MRI surface coil detectors for use in a hybrid MRI - linear accelerator. Radiation dose to skin can cause serious reactions and skin dose is enhanced when materials are placed in the radiation beam. Therefore increases in skin dose due to surface coils must be minimized by optimized construction. A copper conductor causes a three-fold increase in skin dose compared to a similar thickness aluminum conductor. An aluminium coil (20 μm thick) was used to image a phantom, yielding 93% of the SNR achieved with a copper tape coil (32 μm thick).

4436

Computer 63

A MRI Compatible Class-EF Power Amplifier Designed to Drive a Wireless Power Transfer System

Kelly Byron¹, Fraser Robb², Shreyas Vasanawala³, John Pauly¹, and Greig Scott¹

¹Electrical Engineering, Stanford University, Stanford, CA, United States, ²GE Healthcare, Aurora, OH, ³Radiology, Stanford University, Stanford, CA

A compact wireless power transfer (WPT) system being used to power wireless patient coils would require a compact power amplifier that can operate inside the MRI bore. A Class-EF power amplifier is designed and implemented that uses air-core inductors and is capable of driving the coupled resonant coils used for WPT with similar efficiency to a system that uses a large and expensive power amplifier that is outside the scan room. This new power amplifier is very compact and is also very cost-effective.

Computer 66

RF Coil Performances in Compact Hybrid MR/PET Scanner Design Using an Integrated Shielding

Arne Berneking¹, Adam Mehina, and N. Jon Shah

¹Institute of Neuroscience and Medicine, Forschungszentrum Juelich GmbH, Juelich, Germany

The goal of this study is to demonstrate hybrid MR/PET scanner design optimization methods from an RF coil perspective with a focus on UHF MRI. Here, coil performances are investigated depending on different shielding distances to present simulation and measurement methods to include RF coil performances into the hybrid MR/PET scanner design. Moreover, integration of PET detector shielding and RF coil shield is investigated. The results of this study clarify that a trade of between a compact design, PET and RF coil performances is necessary and that RF coil performances can be optimized by an integrated shielding with an optimized configuration.

Computer 68

A novel method to maintain PET detector performance in the presence of MR gradient induced heating

Mohammad Mehdi Khalighi¹, Tuoyu Cao², Mark Fries³, Timothy W. Deller², Floris Jansen², and Gary Glover⁴

¹Applied Science Lab, GE Healthcare, Menlo Park, CA, United States, ²PET/MR engineering, GE Healthcare, Waukesha, WI, United States, ³Imaging Subsystems, GE Healthcare, Waukesha, WI, United States, ⁴Radiology Department, Stanford University, Palo Alto, CA, United States

In a simultaneous ToF-enabled SiPM PET/MR scanner, eddy currents induced by the changing gradient field lead to increased temperature around the PET detectors; this can change the detector gain and shift the position of the photopeak in the spectrum, reducing accuracy of the reconstructed image. Conventionally, peak stability is achieved by thermal monitoring system and adjusting the gain based on the temperature. A more accurate gain control algorithm is presented, which analyzes the spectrum of single events detected on each device. Reconstructed activity of a PET phantom in extreme MR gradient switching is measured to remain stable, better than 0.5%.

Ultrasound-based Cardiac Gating for MRI

Frank Preiswerk¹, Cheng-Chieh Cheng¹, Pei-Hsin Wu¹, Lawrence P. Panych¹, and Bruno Madore¹

¹Department of Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States

Clinical cardiac MRI typically requires the use of electrocardiogram (ECG) leads to detect R-waves and synchronize the MRI acquisition accordingly. The magnetohydrodynamic effect can corrupt the ECG signal, sometimes making R-wave detection difficult, especially at higher field strengths. We are proposing here a practical and low cost ultrasound-based solution for detecting cardiac activity in a manner immune to the presence and strength of the B₀ field. Equivalence was shown in cases where ECG gating worked well. In the future, the approach should prove most helpful as an alternative to ECG when the latter proves impractical, especially at higher field strengths.

4444

Computer 71

RF-sensing for Trigger-based Synchronization of Auxiliary Devices, and Pulse-sequence Debugging

Frank Preiswerk¹, Jiarui Cai², Cheng-Chieh Cheng¹, W. Scott Hoge¹, Pei-Hsin Wu¹, Lawrence P. Panych¹, and Bruno Madore¹

¹Department of Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ²Beijing University of Posts and Telecommunications, Beijing, People's Republic of China

Voltage or laser-light triggers are often used to synchronize auxiliary devices to the MR acquisition process. A very simple RF antenna and associated circuit is proposed here instead. The device is used here to trigger ultrasound probe firings, as part of a hybrid ultrasound-MRI system, but could be used for other purposes as well. Compared to scanner-generated triggers, advantages include: 1) vendor- and software release-independent, 2) available in the scan room, 3) no change to product sequences needed, and 4) the little device proved handy for pulse sequence debugging as well.

4445

Computer 72

A Novel Cryogenic Radio-Frequency Probe for High Spatial Resolution Fluorine-19 MRI of Brain Inflammation

Andreas Pohlmann¹, Jason M Millward¹, Paula Ramos Delgado¹, Daniel Marek², Didier Wecker³, Ralph Wissmann³, Helmar Waiczies⁴, Thoralf Niendorf^{1,5}, and Sonia Wacizies¹

¹Berlin Ultrahigh Field Facility (B.U.F.F.), Max Delbrueck Center for Molecular Medicine, Berlin, Germany, ²Bruker BioSpin AG, Fällanden, Switzerland, ³Bruker BioSpin MRI GmbH, Ettlingen, Germany, ⁴MRI TOOLS GmbH, Berlin, Germany, ⁵Experimental and Clinical Research Center (ECRC), a joint cooperation between the Charité Medical Faculty and the Max Delbrueck Center, Berlin, Germany

MRI using i.v. administered fluorine-19 loaded nanoparticles (NPs) allows the tracking of inflammatory cell migration. The inherently low SNR limits the precise localization of 19F-labeled inflammatory cells, because large voxel sizes are needed to collect sufficient signal. To overcome this, we show here the first use of a novel 19F cryogenic quadrature RF surface probe at ultrahigh field to substantially boost SNR beyond that of state-of-the-art room temperature RF coils, while facilitating the acquisition of better spatially-resolved images within shorter scan times.

A clinically-validated, fast and semi-automated MR workflow for Liver Evaluation

Qingsong Yang¹, Yukun Chen¹, Caixia Fu², Bernd Kuehn³, Berthold Kiefer³, Zhen Wang¹, Xu Yan⁴, Chao Ma¹, Dehe Weng², Luguang Chen¹, and Jianping Lu¹

¹Department of Radiology, Changhai Hospital of Shanghai, the Second Military Medical University, Shanghai, People's Republic of China, ²Application development, Siemens Shenzhen Magnetic Resonance Ltd., Shenzhen, People's Republic of China, ³MR Applications Predevelopment, Siemens Healthcare, Erlangen, Germany, ⁴MR Collaboration NE Asia, Siemens Healthcare, Shanghai, People's Republic of China

A fast and semi-automated MRI workflow for liver examinations with approximately 12mins of total examination time was proposed and evaluated with liver patients using CT or histo-pathology as reference. 28 patients suspected of liver disease were enrolled in this study. The results show a good concordance between findings on MRI and the chosen reference standard. This indicates that the proposed fast MRI workflow has the capability to be used for diagnostic purposes in clinical routine while being highly time efficient at the same time.

4447

Computer 98

Increasing value of MRI in evaluation of gynecologic malignancies by decreasing scan time and reducing artifacts through the replacement of fast spin echo (FSE) with variable refocusing flip angle single-shot FSE (vrfSSFSE)

Paul Benjamin Stoddard¹, Valentina Taviani², Daniel V. Litwiller², Michael C. Muelly¹, Shreyas S. Vasanaawala¹, and Andreas M. Loening¹

¹Radiology, Stanford University, Stanford, CA, United States, ²Global MR Applications and Workflow, GE Healthcare

Variable refocusing flip angle single-shot fast spin echo (vrfSSFSE) with outer volume suppression (OVS) improves upon standard single-shot fast spin echo (SSFSE or HASTE): 1) decreasing average flip angles thereby reducing specific absorption rate (SAR) limited acquisition times, 2) reducing blurring from T2 decay, 3) allowing full-Fourier acquisitions. Although improving upon conventional SSFSE, it remains unknown if vrfSSFSE with OVS can approach the image quality and diagnostic capability of fast spin echo (FSE). We found vrfSSFSE comparable to FSE in signal-to-noise and contrast and superior to FSE in coherent artifact reduction, depending on the plane of imaging.

Trisha L. Roy^{1,2}, Howard Chen¹, Andrew D. Dueck¹, and Graham A. Wright^{1,3}

¹*Schulich Heart Program, Sunnybrook Research Institute, Toronto, ON, Canada*, ²*Division of Vascular Surgery, University of Toronto, Toronto, ON, Canada*, ³*Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada*
- There are two treatment options for revascularizing patients with critical limb ischemia: bypass surgery and percutaneous vascular intervention (PVI). PVI is less invasive but has high immediate technical failure rates (20%) and high re-intervention rates (20%). The most common mode of immediate failure is the inability to enter/cross the lesion. With current imaging (X-ray angiography, CTA, Duplex ultrasound) it is difficult to predict which lesions will be soft enough to cross with a wire to make PVI possible. Physicians have responded with a "percutaneous-first" strategy where they attempt PVI in all patients and perform surgery if PVI fails. This requires more procedures per index limb at significant cost to healthcare systems and delays definitive revascularization. Additionally, there is evidence that surgical bypass after failed PVI results in worse outcomes, including higher amputation rates within 1 year.
- These issues highlight the critical need for improved diagnostic accuracy to inform patient selection. We have developed and validated MR methods to distinguish hard PAD lesions (densely calcified or collagenous) that would be at high risk of PVI failure from soft lesions that would be amenable to PVI. The impact of this work will help to reduce PVI failure rates, reduce time to definitive revascularization and reduce costs for additional procedures and investigations.
-
- 4454 **Computer 105** [Can replacement sagittal diffusion images increase MR value of spinal imaging in patients with suspected malignant disease?](#)
Saurabh Singh¹, Timothy James Pengilley Bray¹, Alan Bainbridge¹, Magdalena Sokolska¹, Shonit Punwani¹, and Margaret A Hall-Craggs¹
¹*Centre of Medical Imaging, University College London, London, United Kingdom*

To increase the MR value of spinal imaging in patients with suspected or known malignant disease, we propose the use of sagittal diffusion weighted imaging as replacement for traditional image types such as STIR and T2W TSE. The impact of this protocol is threefold. Scan times are reduced from potentially 50 minutes to 15 minutes for the whole spine; making scans more tolerable for patients with back pain, reducing cost and increasing scanner capacity. Reader confidence is increased in detecting malignant infiltration especially when diffuse. Finally, read times are reduced as there are fewer images to review.

MR arthrography of the hip using 3D isotropic SPGR reconstructed with ESPIRiT compressed sensing reconstruction and two-point Dixon fat-water separation

Kathryn Jane Stevens¹, Tao Zhang², Marcus T Alley³, and Shreyas S Vasanawala⁴

¹Department of Radiology, Stanford University School of Medicine, Stanford, CA, United States, ²GE Healthcare, ³Department of Radiology, Stanford University School of Medicine, CA, United States, ⁴Stanford University School of Medicine, CA, United States

A single volumetric SPGR sequence reconstructed with ESPIRiT compressed sensing reconstruction and two-point Dixon fat-water separation was added to routine hip MR arthrogram and compared to the conventional 3-plane 2D-FSE fat-saturated T1-weighted sequences in identification of hip pathology in 25 patients. SPGR compared favorably well with T1 FS, but failed to identify 3 subtle labral tears, 1 chondral delamination and 3 low-grade ligamentum teres tears, possibly due to increased blurring associated with SPGR, decreasing overall image quality of SPGR. The relative time saving of SPGR and ability to subsequently reformat data makes this a viable technique for hip MR arthrograms.

Quality Assessment in the Multicenter MR Imaging Study of the German National Cohort (NAKO)

Jochen G. Hirsch¹, Alexander Köhn², Daniel C. Hoinkiss¹, Jonas Singe², Eyyub Ebu-Bekir Öztürk¹, Matthias Günther¹, and the NAKO MRI Study Investigators³

¹MR Physics and Imaging, Fraunhofer MEVIS, Bremen, Germany, ²Software Development, Fraunhofer MEVIS, Bremen, Germany, ³Central Executive Office of the German National Cohorte, Heidelberg, Germany

A fully automated workflow for image-based quality assessment (QA) was set up in a large, multi-center cohort whole-body MR imaging study, part of the National Cohort Study Germany NAKO. Study design, data management, workflow, and objectives have been described previously. Standardized quality assessment including technical aspects like program and protocol parameter truth, as well as image-based estimates of various quality indices demonstrate a high degree of stability and homogeneity of image quality across the 5 contributing MR centers. Furthermore, QA ensures short-term intervention procedures with respect to quality control, and offer valuable quantitative information for subsequent scientific data evaluation.

MRI evaluation of suspected appendicitis in pediatric patients

Christina L Sammet^{1,2}, Cindy Rigsby^{1,2}, Barb Karl¹, Laura Gruber¹, and Jie Deng^{1,2}

¹Medical Imaging, Lurie Children's Hospital of Chicago, Chicago, IL, United States, ²Radiology, Northwestern University, Chicago, IL, United States

Appendicitis is prevalent in pediatric populations and currently CT imaging is used to triage children to emergency surgery. As of early 2015 we have been able to replace this CT scan with a limited abdomen/pelvis study using MRI. This limited MRI appendicitis protocol is rapid, cost-neutral (equal in cost to our previous CT study for appendicitis), and confers less potential risk to the child by eliminating radiation exposure. Using state-of-the-art rapid MRI imaging techniques, we have been successful in imaging suspected appendicitis in children as young as five years old.

Using Hippocampus Volume to Predict Treatment Outcome in Major Depressive Disorder

Xiaoxiao Hu¹, Lianqing Zhang¹, Ming Zhou¹, Lu Lu¹, Xinyu Hu¹, Qiyong Gong¹, and Xiaoqi Huang¹

¹Department of Radiology, Huaxi MR Research Center (HMRR), West China Hospital of Sichuan University, Chengdu, People's Republic of China

The current study aimed to use structural data of hippocampus volume obtained from magnetic resonance imaging to predict treatment outcome in major depressive disorder. Our findings demonstrated that there was a relationship between left hippocampus volume and medication efficiency in major depressive disorder group. Meanwhile, our results threw light on the predictive value as a marker of treatment responsiveness in major depressive disorder.

Computer 113 **Voxel-wise meta-analysis of resting-state functional activity in type 2 diabetes**

Taiyuan Liu¹, Jia Liu², Wenhui Wang¹, Lun Ma¹, Xiaoyue Ma¹, Shaojie Shi¹, Qiyong Gong³, and Meiyun Wang¹

¹Henan Provincial People's Hospital, Zhengzhou, People's Republic of China, ²Huazhong University of Science and Technology, Wuhan, People's Republic of China, ³Department of Radiology, West China Hospital of Sichuan University, Zhengzhou, People's Republic of China

Previous studies about resting-state functional activity reported that altered brain activity was demonstrated with type 2 diabetes and their findings were inconsistent, which have not been quantitatively reviewed. Therefore, we conducted a quantitative meta-analysis including resting-state functional activity studies of patients with type 2 diabetes. Meta-analysis of pooled and subgroup meta-analyses found that type 2 diabetes patients showed abnormal brain activity mainly in default mode network(DMN) and visual-related regions. Our finding supports that type 2 diabetes could lead to diabetic brain activity alterations, which may correlate with cognitive impairment of type 2 diabetes patients.

4462

Computer 114 **Simultaneous Perfusion Imaging with Consecutive Echoes (SPICE)**

Michael Schmainda¹

¹Imaging Biometrics, LLC, Elm Grove, WI, United States

SPICE (simultaneous perfusion imaging with consecutive echoes) is a method that permits simultaneous estimation of DSC- and DCE-MRI parameters, in one acquisition, using a single dose of contrast agent. Conventional algorithms are used to obtain the perfusion and permeability parameters corrected for confounding recirculation and leakage effects. The proposed method does not require administration of a loading dose of contrast agent (traditionally employed for DSC), and pre-contrast spin density and native T1 calibration scans (traditionally required for DCE) have been eliminated.

Clinical Impact of Reduced Spectral Acquisitions in Calibrated 3D Multi-Spectral Imaging Near Metal Implants

Rajeev R Mannem¹, Sujan Fernando¹, Sean Lehner¹, Suryanarayanan Kaushik², and Kevin Koch¹¹Radiology, Medical College of Wisconsin, Milwaukee, WI, United States, ²Applications and Workflow, GE Healthcare

We present the clinical evaluation results of a novel approach for acquisition time reduction in 3D multispectral imaging near implants. Two musculoskeletal radiologists compared standard MAVRIC SL sequences to spectrally calibrated MAVRIC SL sequences for exams of instrumented hips, knees, and shoulders. Initial results demonstrated maintenance of diagnostic information in the hips when the calibration is utilized. Rotator cuff evaluation was still limited in the shoulder using the calibrated technique but evaluation of the other structures was nearly equivalent. Calibrated imaging of the knee showed reductions of SNR, which will inform future adjustment of targeted calibrated protocols in this joint.

¹Division of Radiotherapy and Imaging, The Institute of Cancer Research, London, United Kingdom, ²MRI Unit, The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom, ³Division of Molecular Pathology & Centre for Evolution and Cancer, The Institute of Cancer Research, London, United Kingdom, ⁴Institute of Circulation and Medical Imaging, NTNU - Norwegian University of Science and Technology, Trondheim, Norway

In this preclinical study we investigate the utility of in-silico simulations of the pseudo-apparent diffusion coefficient (pADC) of water within extranuclear regions segmented on large field-of-view haematoxylin, eosin, and saffron (HES) slides from a transgenic mouse model of prostate cancer. We demonstrate that pADC is correlated within in-vivo measurements of the apparent diffusion coefficient (ADC) measured by diffusion-weighted magnetic resonance imaging and may thus be used as a surrogate for exploring the effect of tissue structure on measured ADC values. Furthermore, we demonstrate that ADC is correlated with fractional space occupied by lumen, derived from semi-automatic segmentation of HES slides.

Tumor vasculature differs between cell and fragment derived murine orthotopic models of hepatocellular carcinoma

Sibu P Kuruvilla¹, Colleen A Crouch², and Joan M Greve²¹Materials Science and Engineering, University of Michigan at Ann Arbor, Ann Arbor, MI, United States, ²Biomedical Engineering, University of Michigan at Ann Arbor, Ann Arbor, MI, United States

We report the use of semi-quantitative dynamic contrast enhanced (DCE)-MRI to identify differences in the growth and vascular environment seen within two murine hepatocellular carcinoma (HCC) models - cellular orthotopic injection (COI) (representing a traditional tumor model) or surgical orthotopic implantation (SOI) of tumor fragments (representing a patient-derived orthotopic xenograft model, or PDOX). Uptake curves of gadolinium contrast agent indicate differences in vasculature between the two models, highlighting important considerations to be made when trying to use PDOX methods to model HCC in the clinic.

Papillary thyroid carcinoma with hobnail pattern: unique MRI features and correlated with the histopathologic findings

Lanyun Wang¹¹Shanghai Minhang District Central Hospital, Shanghai, People's Republic of China

Hobnail papillary thyroid carcinoma (HPTC) is a moderately differentiated PTC variant with aggressive clinical behavior and significant mortality. The purpose of this study was to recognize the unique MRI features of HPTC. 61 patients with PTC confirmed histopathologically [19 lesions of HPTC and 42 NHPTC (PTC without hobnail features) lesions] undergoing MRI with T1W, T2W, DWI and contrast material-enhanced sequences prior to thyroidectomy were included retrospectively. There was a significant tendency toward T2WI significantly high signal, T2WI linear low signal, lace-like structure, gyrus-like structure, higher ADC values, irregular shape present in HPTCs. HPTC lesions have unique MRI features.

 Leslie R. Euceada¹, Matthew D. Blackledge², Andreas Heindl², Yinyin Yuan², Dow-Mu Koh^{2,3}, David Collins^{2,3}, Siver A. Moestue¹, Martin O. Leach^{2,3}, Tone F. Bathen¹, and Deborah K. Hill¹

¹Institute of Circulation and Medical Imaging, NTNU - Norwegian University of Science and Technology, Trondheim, Norway, ²Institute of Cancer Research, London, United Kingdom, ³MRI Unit, Royal Marsden Hospital, London, United Kingdom
 The relationship between tissue microstructure and ADC is poorly understood in cancer. We identified quantitative nuclear characteristics from haematoxylin, eosin, and saffron stained prostatic histology samples. ADC maps were calculated for transgenic prostate cancer mice and healthy controls. Matched histology images of excised prostates were used to determine cellularity and histological class. ADC and cellularity correlated with a set of nuclear features (describing texture, lightness, radius, and shape), which exhibited mirrored trends, implying an inverse relationship between ADC and cellularity. The same nuclear features correlated with histological class. This will be useful for underpinning relationships between ADC and tissue microstructure.

¹Division of Radiotherapy and Imaging, The Institute of Cancer Research, London, United Kingdom, ²Histopathology Department, Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom, ³Birth Defects Research Centre, Institute of Child Health, University College London, London, United Kingdom, ⁴Division of Clinical Sciences, The Institute of Cancer Research, London, United Kingdom
 Tumours in *Hesx1*^{Cre/+};*Ctnnb1*^{lox(ex3)/+} mice resemble human adamantinomatous craniopharyngioma (ACP) molecularly and histologically. MRI and *ex vivo* micro-CT were used to assess the radiology of this model for the first time. Early enlargement and heterogeneity of *Hesx1*^{Cre/+};*Ctnnb1*^{lox(ex3)/+} pituitaries was evident; enlargement of a solid tumour, and development of cysts and haemorrhage subsequently occurred. Solid components showed heterogeneous T₁-weighted signal enhancement following Gd-DTPA administration, and in some animals cysts were hyperintense on FLAIR and T₁-weighted images, both emulating clinical observations. Cyst calcification was not observed by micro-CT but we show that *Hesx1*^{Cre/+};*Ctnnb1*^{lox(ex3)/+} tumours faithfully recapitulate the MRI radiology of the human disease.

- 4472 **Computer 8** **Molecular effects of various chemotherapeutic agents on choline phospholipid metabolism of triple-negative breast cancer cells**
 Menglin Cheng¹, Zaver M. Bhujwalla¹, and Kristine Glunde¹

¹Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, United States
 The MRS-detected total choline (tCho) signal is a promising non-invasive surrogate marker of chemotherapy response in breast cancer patients. The molecular mechanisms by which common chemotherapeutic drugs affect the tCho signal, consisting of glycerophosphocholine (GPC), phosphocholine (PC), and free choline (Cho), are unknown. We have employed widely used cancer chemotherapeutic drugs including doxorubicin, paclitaxel, and vinorelbine to treat triple-negative human MDA-MB-231 breast cancer cells to elucidate their molecular effects on choline phospholipid metabolism using high-resolution ¹H MRS to detect changes in cellular choline metabolite profiles, and quantitative RT-PCR to assess the corresponding changes in the expression levels of choline-metabolizing enzymes.

 Santosh K Bharti¹, Paul T Winnard Jr.¹, Louis Dore-Savard², Yelena Mironchik¹, Marie-France Penet^{1,3}, and Zaver M Bhujwalla^{1,3}

¹JHU ICMIC Program, Division of Cancer Imaging Research, The Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²Experimental Therapeutics and Metabolism Program, McGill University Health Center, Montreal, QC, Canada, ³Sidney Kimmel Comprehensive Cancer Center, The Johns Hopkins University School of Medicine, Baltimore, MD, United States
 Tumor interstitial fluid (TIF) contains the secretome of cancers that can impact most phenotypic aspects of cancer. One characteristic phenotype of pancreatic ductal carcinoma (PDAC) is its ability to induce profound weight loss or cachexia through a multifactorial syndrome that affects multiple organs. To understand the interaction between cancer cells and body organs, here, for the first time, we have characterized the metabolomic profile of TIF from cachexia and non-cachexia inducing pancreatic cancer xenografts and identified clear differences in the metabolic secretome between cachexia inducing and the non-cachexia inducing tumors.
-
- 4474 **Computer 10** **Metabolic reprogramming in a relevant IDH1-mutated human glioma xenograft model**
 Tom Peeters¹, Krissie Lenting², Jack van Asten¹, William Leenders², and Arend Heerschap¹

¹Radiology and Nuclear Medicine, Radboud university medical center, Nijmegen, Netherlands, ²Pathology, Radboud university medical center, Nijmegen, Netherlands

Understanding metabolic aberrations in IDH-mutated gliomas requires xenograft models growing in a relevant tissue microenvironment and resembling its human genetic counterparts. We performed *in vivo* ¹H MRSI of human-derived oligodendroglioma xenograft models to map lactate and total choline concentrations. Lactate levels were significantly lower and total choline higher in mutated tumor tissue compared to non-tumor brain in the same animal, or to its wild-type counterpart model. This outcome was correlated with expression levels of enzymes and transporters in both lactate- and phospholipid-related metabolic pathways. The findings point to a metabolic reprogramming of aerobic glycolysis and lipid synthesis by the IDH1 mutation.

Intratumoral vessel evaluation using magnetic resonance micro-angiography with a vascular pool Gd-DOTA-dendron liposomal contrast agent Nobuhiro Nitta^{1,2}, Daisuke Kokuryo³, Sayaka Shibata¹, Kenji Kono⁴, Akihiro Tomita⁵, Jeff Kershaw¹, Ichio Aoki¹, and Masafumi Harada²

¹Department of Molecular Imaging and Theranostics, National Institute of Radiological Sciences, National Institutes for Quantum and Radiological, Chiba, Japan, ²Radiology and Radiation Oncology, Graduate School of Medicine, Tokushima University, Tokushima, Japan, ³Graduate School of System Informatics, Kobe University, Hyogo, Japan, ⁴Graduate School of Engineering, Osaka Prefecture University, Osaka, Japan, ⁵Graduate School of Medicine, Nagoya University, Aichi, Japan

Evaluation of the intratumor environment, such as cell distribution and vessel structure, are important for understanding the characteristics of tumors. In particular, the vessel structure and its permeability is critical for the malignant potential of the tumor and drug-targeting. The purpose of this work was to non-invasively visualize intratumoral vessels using MR micro-angiography (MRmA) and a liposomal contrast agent having long blood half-life. In addition, we tried to identify differences in the vascular structures for Colon26 and SU-DHL6 cells. The proposed method visualized the intratumoral vessels clearly and revealed differences in the structure depending on the cell type.

Electric field and current density mapping during reversible Electroporation

Munish Chauhan¹, Neeta Ashok Kumar¹, Vikram D Kodibagkar¹, and Rosalind J Sadleir¹

¹School of Biological and Health Systems Engineering, Arizona State University, Tempe, AZ, United States

Electroporation is popular in cancer therapy and gene or drug delivery. Magnetic Resonance Electrical Impedance Tomography (MREIT) was used to monitor the applied electric field and current density during electroporation. Electroporation fields were applied by novel low-susceptibility carbon fiber electrodes in a bovine liver tissue sample. Projected current density (J^p) and Electric field (E) were computed from MR data collected under electroporation fields. Susceptibility artifacts around the pair of carbon fiber electrodes were greatly reduced. In this study, we demonstrated the feasibility of MREIT technique to monitor the current density and electric field distribution during ex-vivo tissue electroporation.

Diffusion Kurtosis Imaging Evaluating Epithelial-mesenchymal Transition in Colorectal Carcinoma Xenografts Model: Initial Experience

Huanhuan Liu¹, Caiyuan Zhang², Jinning Li², Weibo Chen³, and Dengbin Wang²

¹Department of Radiology, Xinhua hospital, Shanghai Jiaotong University School of Medicine, Shanghai, People's Republic of China, ²Department of Radiology, Xinhua hospital, Shanghai Jiaotong University School of Medicine, People's Republic of China, ³Philips Healthcare, People's Republic of China

Colorectal cancer (CRC) is one of the most common malignant tumors in gastrointestinal tract. Tumor recurrence and metastasis are still a major cause of death in rectal cancer patients. Epithelial-mesenchymal transition (EMT) is reported a critical process providing tumor cells with the ability to migrate and metastasize to distant sites, leading to a poor prognosis in CRC. The diffusion kurtosis imaging (DKI) could quantify non-Gaussian behavior of water diffusion and provide more precise information of tissue characteristics. Our study demonstrated that DKI could be used to identify EMT in CRC xenograft models.

Telomerase expression enhances pentose phosphate pathway flux resulting in an MR-detectable increase in reduced glutathione levels in mutant IDH1 glioma cells

Pavithra Viswanath¹, Russell O Pieper², and Sabrina M Ronen¹

¹Radiology and Biomedical Imaging, University of California San Francisco, San Francisco, CA, United States, ²Neurological Surgery, University of California San Francisco, San Francisco, CA, United States

Telomerase is the enzyme responsible for maintenance of telomeres, which are special capped structures that protect chromosomal ends from degradation. Telomerase activation and metabolic reprogramming have both emerged as hallmarks of cancer. Here, we investigated the link between telomerase and metabolism in mutant isocitrate dehydrogenase 1 (IDH1) glioma cells with the goal of identifying MR-detectable biomarkers of telomerase expression. Using ^{13}C - and ^1H - MRS, we show that telomerase expression is associated with elevated flux through the pentose phosphate pathway resulting in increased levels of reduced glutathione (GSH). Thus, GSH is a potential biomarker of telomerase expression in mutant IDH1 gliomas.

Dietary Fat Results in Increased Tumor Burden in a Mouse Model of Human Triple-Negative Breast Cancer Based on Magnetic Resonance Imaging and Histology

Devkumar Mustafi¹, Sully Fernandez², Erica Markiewicz¹, Xiaobing Fan¹, Marta Zamora¹, Jeffrey Mueller³, Matthew J Brady², Suzanne D Conzen⁴, and Gregory S Karczmar¹

¹Radiology, The University of Chicago, Chicago, IL, United States, ²Medicine, Sections of Adults and Pediatric Endocrinology, Diabetes and Metabolism, The University of Chicago, Chicago, IL, United States, ³Pathology, The University of Chicago, Chicago, IL, United States, ⁴Medicine, the Section of Hematology and Oncology, The University of Chicago, Chicago, IL, United States

Breast cancer is the most commonly diagnosed malignancy among women in the United States and the second leading cause of cancer mortality worldwide. Epidemiological studies suggest an increase in the risk of triple-negative breast cancer (TNBC) in association with a high animal fat diet. Based on previous MRI studies in SV40Tag mice, we examined the effect of pre-pubertal exposure to high dietary fat in this model of TNBC. The results reported here demonstrate that a high animal fat diet significantly increased the number of aggressive cancers detected by MRI in a mouse model of human TNBC.

Magnetic Resonance Angiography Shows Increased Arterial Blood Supply Associated with Murine Mammary Cancer

Devkumar Mustafi¹, Abby Leinroth¹, Xiaobing Fan¹, Erica Markiewicz¹, Marta Zamora¹, Jeffrey Mueller², Suzanne D Conzen³, and Gregory S Karczmar¹

¹Radiology, The University of Chicago, Chicago, IL, United States, ²Pathology, The University of Chicago, Chicago, IL, United States, ³Medicine, the Section of Hematology and Oncology, The University of Chicago, IL, United States

Breast cancer is a major cause of morbidity and mortality in Western women. Tumor neo-angiogenesis may be an MRI-detectable prognostic marker for cancer progression. Clinical practice uses DCE-MRI to detect cancers based on increased blood flow and capillary permeability. However, DCE-MRI requires repeated injections of contrast media; therefore we used time-of-flight MR angiography to measure the number and size of arteries feeding mammary glands with and without cancer, and demonstrated that blood vessels in and near mammary glands grew significantly as invasive cancers developed.

Computer 18

In vivo hyperpolarized [$1\text{-}^{13}\text{C}$]pyruvate and [^{18}F]-FDG PET/CT studies of prostate cancer metastasis xenografts in mice

Frits H.A. van Heijster¹, Sandra Heskamp¹, Andor A. Veltien¹, Tom H. Peeters¹, Tom W.J. Scheenen¹, Otto C. Boerman¹, and Arend Heerschap¹

¹Radiology and Nuclear Medicine, Radboud University Medical Center, Nijmegen, Netherlands

Understanding the underlying mechanisms of aggressiveness is important for better staging and treatment of prostate cancer. In this study two murine xenograft models of early and late stage prostate cancer were investigated. [$1\text{-}^{13}\text{C}$]pyruvate was hyperpolarized by Dynamic Nuclear Polarization (DNP) and pyruvate metabolism is followed by ^{13}C -MR. This is combined with [^{18}F]FDG-PET/CT to study glucose metabolism. We found differences in pyruvate conversion and glucose uptake *in vivo* in the murine models.

4483

Computer 19

Multi-agent dynamic contrast enhanced MRI to assess vascular changes induced by prolonged VEGFR2 inhibition in oesophageal cancer

Remy Klaassen^{1,2}, Anne Steins^{1,2}, Matthias C Schabel^{3,4}, Igor Jacobs⁵, Maarten F Bijlsma², Aart J Nederveen⁶, Gustav J Strijkers⁷, and Hanneke WM van Laarhoven¹

¹Medical Oncology, Academic Medical Center, Amsterdam, Netherlands, ²LEXOR, Academic Medical Center, Amsterdam, Netherlands, ³Advanced Imaging Research Center, Oregon Health & Science University, Portland, OH, United States, ⁴Utah Center for Advanced Imaging Research, University of Utah, Salt Lake City, UT, ⁵Biomedical NMR, Department of Biomedical Engineering, Eindhoven University of Technology, Eindhoven, Netherlands, ⁶Radiology, Academic Medical Center, Amsterdam, Netherlands, ⁷Biomedical Engineering and Physics, Academic Medical Center, Amsterdam, Netherlands

The effective vascular changes induced by prolonged VEGFR2 inhibition and the resulting changes in vascular function are difficult to monitor *in vivo* and therefore largely unexplored. In this study we show a multi-agent DCE-MRI approach, using 3 different-sized contrast agents, to quantify effects on vascularization induced by prolonged VEGFR2 inhibition in an oesophageal cancer mouse model. Effects on vascularization were predominantly observed in parameters dependent on the larger-sized contrast agents, where no effects were found for the traditional low-molecular weight contrast agent.

Computer 21

Imaging Collagenase-Induced Changes in the Mechanical Phenotype of Orthotopic BT474 Breast Cancer Xenografts Using Magnetic Resonance Elastography

Jin Li¹, Jessica K.R. Boulton¹, Craig Cummings¹, Jeffrey C. Bamber¹, Ralph Sinkus², Yann Jamin¹, and Simon P. Robinson¹

¹Division of Radiotherapy & Imaging, The Institute of Cancer Research, London, United Kingdom, ²Division of Imaging Sciences and Biomedical Engineering, King's College London, King's Health Partners, St. Thomas' Hospital, London, United Kingdom

We tested the hypothesis that MRE can inform on collagenase-induced matrix degradation in orthotopic BT474 breast carcinoma xenografts *in vivo*. An acute reduction in the absolute value of the complex shear modulus [G^*] was detected in tumour just 5 hours after collagenase administration, mostly likely a consequence of both collagen degradation and reduction of interstitial fluid pressure. The study highlights the utility of MRE-derived quantitation of tumour viscoelasticity for monitoring the response of stromal rich tumours to modification of the extracellular matrix.

Multiparametric MRI for optimal prostate cancer detection in TRAMP mice

Jana Kim¹, Eugene Kim¹, Deborah K. Hill¹, Dan E. Meyer², Karina Langseth³, Frits A. Thorsen⁴, Tone F. Bathen¹, and Siver A. Moestue¹

¹Department of Circulation and Medical Imaging, NTNU - Norwegian University of Science and Technology, Trondheim, Norway, ²Diagnostics, Imaging and Biomedical Technologies, GE Global Research Center, Niskayuna, NY, United States, ³GE Healthcare AS, Oslo, Norway, ⁴Department of Biomedicine, University of Bergen, Bergen, Norway

Multiparametric MRI is the standard for the detection and characterization of prostate cancer. In this study we compared the diagnostic value of clinically used DW-MRI and DCE-MRI in a transgenic mouse model of prostate cancer (TRAMP). Additionally, we investigated the potential utility of SSC-MRI using a USPIOs contrast agent for prostate cancer detection. The results of this study confirm the utility of DW-MRI and the potential value of DCE-MRI in early-stage detection and monitoring of prostate cancer. SSC-MRI appears to be less useful for this task in the TRAMP model, but further analysis is required to draw a clear conclusion.

Transport across the blood-brain-barrier may be limiting for hyperpolarized [1-13C]pyruvate neuro-oncology studies

Jack Julian James Jenkins Miller^{1,2,3}, James Larkin⁴, Katherine R Fisher¹, Vicky Ball¹, Kevin J Ray⁴, Sebastien Serres⁵, Damian John Tyler^{1,2}, Angus Zoen Lau^{1,6}, and Nicola Ruth Sibson⁴

¹Department of Physiology, Anatomy & Genetics, University of Oxford, Oxford, United Kingdom, ²Oxford Centre for Clinical Magnetic Resonance Research, University of Oxford, Oxford, United Kingdom, ³Department of Physics, University of Oxford, Oxford, United Kingdom, ⁴Cancer Research UK and Medical Research Council Oxford Institute for Radiation Oncology, University of Oxford, Oxford, United Kingdom, ⁵School of Life Sciences, University of Nottingham, Nottingham, United Kingdom, ⁶Physical Sciences, Sunnybrook Research Institute, Toronto, ON, Canada

Hyperpolarized pyruvate has previously been used to probe primary brain cancer. Through imaging the delivery and metabolism of both hyperpolarized [1-¹³C]pyruvate and ethyl-[1-¹³C]pyruvate in a rodent model of cancer metastasis to the brain, we show that the transport of [1-¹³C]pyruvate across the blood brain barrier may be limiting until it is compromised by metastatic cell infiltration.

Validation of an efficient and robust MRI-guided radiotherapy planning approach for targeting abdominal organs and tumours in the mouse.

Veerle Kersemans¹, John S Beech¹, Stuart Gilchrist¹, Paul Kinchesh¹, Philip D Allen¹, James Thompson¹, Ana L Gomes¹, Zenobia D'Costa¹, Luke Bird¹, Iain DC Tullis¹, Robert G Newman¹, Abul Azad¹, Ruth J Muschel¹, Borivoj Vojnovic¹, Mark A Hill¹, Emmanouil Fokas¹, and Sean C Smart¹

¹CRUK/MRC Oxford Institute for Radiation Oncology, University of Oxford, Oxford, United Kingdom

The aim was to develop and validate a robust and accurate method of MR-IGRT delivery to abdominal targets in the mouse that takes advantage of the strengths of each of its components: MRI for soft tissue contrast and target identification, CBCT for accurate dose calculation and IGRT for accurate, collimated X-ray beam delivery. A multimodality cradle was developed and evaluated to enable transfer of the mouse between MR and the IGRT platform. Additionally, each step of the MG-IGRT process was validated, both *in vitro* using BANG gel dosimeters and *in vivo* by targeting the adrenal glands in mice.

Diffusion kurtosis imaging can stratify differentiation of colorectal cancers: a preliminary study

Huanhuan Liu¹, Caiyuan Zhang², Jinning Li³, Weibo Chen⁴, and Dengbin Wang³

¹Department of Radiology, Xinhua hospital, Shanghai Jiaotong University School of Medicine, Shanghai, People's Republic of China,

²Department of Radiology, Xinhua hospital, Shanghai Jiaotong University School of Medicine, ³Department of Radiology, Xinhua hospital, Shanghai Jiaotong University School of Medicine, People's Republic of China, ⁴Philips Healthcare, People's Republic of China

Colorectal cancer (CRC) is the third most common cancer in the world and its incidence is on the rise. Management is particularly challenging technically for surgeon and local recurrence is a common result of treatment failure. Tumor differentiation grade is one of the factors that influence the choice of individual management, then affecting the prognosis. Diffusion kurtosis imaging (DKI) could quantify non-Gaussian behavior of water diffusion and provide more precise information of tissue characteristics. Our study demonstrated that DKI is conducive to distinguishing the various differentiations of CRC models, and reflecting the proliferation indirectly in tumor cells.

Multi-phase contrast-enhanced magnetic resonance imaging with respiratory gating in papillary thyroid carcinoma
Hao Wang¹ and Bin Song²

¹Radiology, Central Hospital of Minhang District, Fudan University, Shanghai, People's Republic of China, ²Radiology, Central Hospital of Minhang District, Fudan University, People's Republic of China

Purpose To investigate the role of multi-phase contrast-enhanced MR imaging in papillary thyroid carcinoma (PTC). **Methods** A consecutive series of 62 lesions with PTC were prospective evaluated by MR imaging. Lesions were evaluated for location, size, shape, margin, rim, degree and pattern of enhancement. **Results** 52 (83.9%) lesions showed moderate enhancement. 45 (72.6%) lesions showed ring-enhancement and 42 (67.7%) showed central washout enhancement during the delayed phase. 36(58.1%) manifested ill-defined margin and irregular rim (49, 79.0%) after administration of the contrast medium. Nine nodules (14.5%) showed extrathyroidal extension. **Conclusion** PTC commonly manifest moderate enhancement during the initial phase, with ill-defined margin and irregular rim. Central wash out enhancement and ring-enhancement occur during delayed contrast –enhanced phase.

Radiological comparisons of 3D and 2D-cell culture derived tumours in an orthotopic mouse xenograft model of paediatric glioblastoma
Mariama Fofana¹, Jessica KR Boulton¹, Maria Vinci¹, Valeria Molinari¹, Sergey Popov¹, Alan Mackay¹, Angel M Carcaboso², Chris Jones¹, and Simon P Robinson¹

¹The Institute of Cancer Research, London, United Kingdom, ²Department of Oncology, Hospital Sant Joan de Déu, Barcelona, Spain

Primary patient-derived paediatric glioblastoma (pGBM) cells, cultured under conditions designed to maintain stem-like phenotypes, provide valuable platforms for pre-clinical research. Culturing tumour cells in suspension (3D) or adherent on laminin (2D) may influence their growth behaviour *in vivo*. Longitudinal, anatomical MRI showed that orthotopic HSJD-GBM-001 xenografts derived from 3D-cultured cells grew significantly faster than those from 2D-culture. Infiltrative tumour growth, maintenance of the blood brain barrier and high ADC, T₁ and T₂, associated with histopathologically confirmed tumour-oedema, were observed in both cohorts. The study highlights the influence of *in vitro* cell culture conditions on *in vivo* tumour growth characteristics.

Application of Cardio-Respiratory Gated High Resolution 3D Balanced SSFP to Liver Tumour Imaging in the Mouse
Ana L Gomes¹, Paul Kinchesh¹, Stuart Gilchrist¹, Alex Gordon-Weeks¹, Ruth J Muschel¹, and Sean C Smart¹

¹CRUK/MRC Oxford Institute for Radiation Oncology, University of Oxford, Oxford, United Kingdom

Prospective gating and automatic reacquisition of data corrupted by respiration motion were implemented in 3D balanced steady-state free precession (bSSFP) to provide contrast that enables unambiguous detection of liver tumours in the whole mouse liver with 200 µm isotropic resolution and in scan times that are routinely less than 7 minutes. The method was used for orthotopic tumour burden quantification in 8 female C57BL/6 mice at days 7, 9, and 11 post intra-hepatic injection of MC38-GFP cells, and enabled measurement of tumour volumes less than 1 mm³.

Early Detection of Glioblastoma Multiforme by the Magnetic Susceptibility Effect from Deoxyhemoglobin
Zhao Li¹, Chaohsiung Hsu¹, and Yung-Ya Lin¹

¹Chemistry and Biochemistry, UCLA, Los Angeles, CA, United States

Early detection of high-grade malignancy, such as glioblastoma multiforme (GBM), using new contrast mechanism and enhanced MRI techniques significantly increases not only the treatment options available, but also the patients' survival rate. For this purpose, the local magnetic-field gradient variations due to irregular water contents and deoxyhemoglobin concentration in early GBM is detected sensitively to provide the needed cancer contrast. Statistical results (N=22) for *in vivo* orthotopic xenografts GBM mouse models at various cancer stages validate the superior contrast and robustness of this approach (tumor time constant differs from that of the healthy brain tissue by +24%) towards early GBM detection than conventional T1-weighted (+2.6%) and T2-weighted images (-3.1%). This novel approach provides 4-8 times of improvements in early GBM tumor contrast, as measured by "tumor to normal tissue contrast", "contrast-to-noise ratio" (CNR) or "Visibility".

On Molecular Aspects of K^{trans} and Angiogenesis: Cerebral Gliomas
Charles S. Springer, Jr.¹, Xin Li¹, Seymour Gahramanov², Martin M. Pike¹, William D. Rooney¹, and Edward A. Neuwelt³

¹Advanced Imaging Research Center, Oregon Health & Science University, Portland, OR, United States, ²Neurosurgery, University of New Mexico, Albuquerque, NM, United States, ³Blood Brain Barrier Program, Oregon Health & Science University, Portland, OR, United States

It is often thought that tumor K^{trans} value differences correspond to changes in capillary contrast agent (CA) permeability. We show this is not the case for implanted glioma in rat brain. Over an almost eight-fold K^{trans} change, the tumor CA extravasation rate constant k_{pe} remains relatively fixed, as if regulated, but at a value greater than normal. The K^{trans} changes reflect cerebral blood volume fraction changes.

¹*Division of Radiotherapy and Imaging, The Institute of Cancer Research, London, London, United Kingdom, ²Division of Cancer Therapeutics and Division of Clinical Studies, The Institute of Cancer Research, London, London, United Kingdom*
- In this study we demonstrate that the transverse relaxation rate R_2^* affords a biomarker of response to a potent anaplastic lymphoma kinase inhibitor in the Th-*ALK*^{F174L}/Th-*MYCN* genetically engineered murine model of neuroblastoma, a childhood cancer of the nervous system
-
- 4496 **Computer 32** [Numerical Model of Bi-Exponential T2 Decay-Based Magnetic Resonance Oximetry Imaging \(MOXI\)](#)

 Tatsuya J Arai¹, Donghan M Yang¹, James Campbell¹, and Ralph P Mason¹
¹*Radiology, UT Southwestern Medical Center, Dallas, TX, United States*
- The present work seeks to explore the accuracy and precision of proton MR oximetry imaging (MOXI) in silico. MOXI technique relies on the separation of oxygen sensitive $T_{2\text{Blood}}$ from the bi-exponential nature of overall T_2 decay. The bi-exponential T_2 decay models with Rician distribution noise were numerically generated, simulating the preclinical prostate tumor model experiments. The present in silico study showed the feasibility of the proton based MOXI technique. However, the results suggest that the MOXI technique may lack the accuracy and precision of measuring short $T_{2\text{Blood}}$ (< 30 ms), which is essential to measure hypoxia in a tumor.
-
- 4497 **Computer 33** [Improved quantification of SPIO in peripheral tumor xenografts using QSM](#)

 Kofi Deh¹, Marjan Zaman, Pascal Spincemaille, Moonsoo Jin, and Yi Wang
¹*Weill Cornell Medical College, New York, NY, United States*
- The use of MRI relaxometry for super-paramagnetic iron oxide (SPIO) quantification in a murine peripheral tumor xenograft, a frequently performed procedure in drug development research, may result in inaccurate estimates because of the dependence of relaxivity on tissue microenvironment. SPIO complexes conjugated to PET radiotracers have been proposed for more accurate SPIO quantification, but these have disadvantages of a cyclotron requirement, low spatial resolution and confounding tumoricidal effects. We demonstrate that SPIO quantification in peripheral tumor xenografts using new quantitative susceptibility mapping (QSM) algorithms has good agreement with quantification using PET suggesting that QSM may provide value for quantification in drug development research.
-
- 4498 **Computer 34** [Probing Tumor Oxygenation Response to Hypoxic Gas Breathing](#)

 Donghan Mo Yang¹, Tatsuya J Arai¹, James Campbell¹, and Ralph P Mason¹
¹*Radiology, The University of Texas Southwestern Medical Center, Dallas, TX, United States*
- Tumor oxygenation response to hypoxic gas breathing is studied in rat 13762NF breast tumors using BOLD and TOLD MRI, with hyperoxic gas breathing as reference. Time course of R_2^* and R_1 -weighted signal is analyzed for 100%, 16%, and 14% O_2 breathing challenges, respectively. Evidence for decreased blood oxygen saturation (sO_2) and decreased tissue oxygen partial pressure (pO_2) is observed, revealing different patterns depending on the tumor size.
-
- 4499 **Computer 35** [Characterization of Intratumoral Heterogeneity Based on BOLD Effect: A Study in 13762NF Breast Tumor](#)

 Donghan Mo Yang¹, Tatsuya J Arai¹, James Campbell¹, and Ralph P Mason¹
¹*Radiology, The University of Texas Southwestern Medical Center, Dallas, TX, United States*
- Characterization of intratumoral heterogeneity is crucial for the accuracy and specificity of MRI evaluation of cancer. BOLD MRI, which is widely used for investigating tumor oxygenation, is sensitive to the structure and function of tumor vasculature. We present a method, based on BOLD effect (R_2^* dynamics), for differentiating subregions in rat 13762NF tumors that show different degrees of sensitivity with respect to hyperoxic and hypoxic gas breathing challenges. We further show the potential connection between the classified heterogeneity and tumor growth.
-
- 4500 **Computer 36** [Diffusion MRI can provide non-invasive early biomarkers of the outcome of irreversible electroporation tumor treatment in a mouse model.](#)

 Matteo Figini¹, Zhanliang Su¹, Tianchu Lyu¹, Xifu Wang¹, Xiaoke Huang¹, Daniel Procissi¹, Andrew Christian Larson¹, and Zhuoli Zhang¹
¹*Radiology, Northwestern University, Chicago, IL, United States*
- This study investigates diffusion MRI changes after treatment with irreversible electroporation (IRE) in a murine cancer model. The mean and standard deviation of the ADC in regions of interest covering the whole tumors increased 1 day after treatment and then returned gradually to the pre-treatment values. A strong correlation was found between the volume increase and the maximum relative change in ADC mean and standard deviation. Therefore we propose diffusion MRI as an early tool to predict the outcome of IRE treatment in tumors.
-
- 4501 **Computer 37** [Extracting oxygen-enhancing components from OE-MRI using ICA](#)

 Firas Moosvi¹, Jennifer H.E. Baker², Andrew Yung³, Piotr Kozlowski³, and Stefan Reinsberg¹
¹*Department of Physics & Astronomy, University of British Columbia, Vancouver, BC, Canada, ²Department of Integrative Oncology, BC Cancer Research Centre, ³UBC 77 MRI Research Centre, University of British Columbia*

MRI methods to assess tissue oxygenation have recently flourished. Here we explore how a common signal processing technique (independent component analysis) can be used to extract and amplify signal from oxygen stimuli in mouse tumours. With just dynamic T1-weighted images and ICA to extract the enhancing pixels, we can create rich parameter maps corresponding to a response to an oxygen challenge.

Computer 38

Extracellular-extravascular accumulation of non-caloric sweetener (sucralose) provides CEST contrast for cancer detection

Puneet Bagga¹, Mohammad Haris², Kevin D'Aquilla¹, Francesco Marincola², Hari Hariharan¹, and Ravinder Reddy¹

¹Department of Radiology, University of Pennsylvania, Philadelphia, PA, United States, ²Research Branch, Sidra Medical and Research Center, Doha, Qatar

We show the utility of a non-nutritive sweetener, sucralose, as a contrast agent in cancer MRI studies by exploiting its chemical exchange saturation transfer (sucCEST) property. The extracellular-extravascular accumulation of sucralose in a glioma model provides localized, temporal changes in the CEST contrast, corroborating the gadolinium-enhanced MRI. These findings illustrate the potential of sucCEST for diagnosis and monitoring of the therapeutic response of cancers, including gliomas in preclinical studies.

Characterization of lymph nodes in colorectal cancer using non-exponential modeling of T2* decay

Inês Santiago¹, Andrada Ianus^{1,2}, Celso Matos¹, and Noam Shemesh¹

¹Champalimaud Research, Champalimaud Centre for the Unknown, Lisbon, Portugal, ²Centre for Medical Image Computing, Dept. Computer Science, University College London, London, United Kingdom

Lymph node staging is determinant in the management of cancer patients. Noninvasive imaging modalities have limited accuracy to distinguish malignant from benign lymph nodes. For that purpose, we investigated putative nonexponential (multicompartmental) and potentially non-monotonic decay in simple multi-gradient-echo(MGE) MRI in colorectal cancer. We find that frequency offsets arising from multicompartment models distinguish malignancy from normal tissues (as identified from histopathology), while relaxation rates or fractions do not. Such experiments are potentially suggestive of a simple yet useful tool for nodal staging.

Computer 40

Evaluation of PET and MR datasets in integrated 18F-FDG PET/MRI: a comparison of different MR sequences for whole-body restaging of breast cancer patients.

Johannes Grueneisen¹, Axel Wetter, Julian Kirchner, Sonja Kinner, Verena Ruhlmann, Michael Forsting, and Lale Umutlu

¹Diagnostic and Interventional Radiology, University Hospital Essen, Essen, Germany

Simultaneous PET/MR imaging has been successfully implemented for whole-body staging of numerous tumor entities within the last four years. However, to date, the introduced study protocols were acquainted with prolonged examination times, potentially impeding patient comfort and patient compliance. The present results demonstrate the high diagnostic capability of integrated PET/MR imaging for staging patients with suspected breast cancer recurrence. Furthermore, facing the need for an optimization of dedicated MR study protocols for whole-body PET/MR imaging on oncological purposes, the present data support the application of fast, yet morphologically adequate PET/MR protocols, leaving the application of contrast-agent and DWI debatable.

Computer 41

A novel DTI derived heterogeneity index discriminating liver metastasis from normal appearing liver tissue: a PET-MRI study

DAN STEIN^{1,2}, Natalia Goldberg¹, Liran Domachevsky¹, Hanna Bernstine¹, Meital Nidam¹, Dorit Stern¹, Ifat Abadi-Korek¹, Jacob Sosna¹, and David Groshar¹

¹Radiology, Assuta Medical Center, Tel-Aviv, Israel, ²Anatomy & Anthropology, Tel-Aviv University

This study's purpose was to compare DTI heterogeneity index with F18 fluorodeoxyglucose (FDG) standardized uptake value (SUVpeak) in liver metastases and in normal appearing liver tissue. The newly defined diffusion coefficient index (DCV) showed a stronger correlation to SUVpeak ($r=0.714$, $p<0.001$) than any other MR metrics evaluated. A threshold of $DCV > 0.05$ and $SUVpeak > 2.88$, correctly classified 28/35 (80%) and 32/35 (91.43%) liver metastases with AUC of 0.939 and 0.989, respectively. DCV, may provide quantitative data of tissue heterogeneity associated with liver metastases. In addition, DCV introduces a potential biomarker index as a quantitative discriminator of liver metastases.

4506

Computer 42

Exploring flow effects on BOLD MRI with oxygen challenge in orthotopic lung tumor model

Heling Zhou¹, Zhongwei Zhang¹, Zhang Zhang², Jo Wagner¹, James Campbell¹, Shanrong Zhang³, Debabrata Saha², Masaya Takahashi³, and Ralph P Mason¹

¹Radiology, Univ Texas Southwestern Medical Center, Dallas, TX, United States, ²Radiation Oncology, Univ Texas Southwestern Medical Center, Dallas, TX, United States, ³Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, TX, United States

Blood oxygen level dependent (BOLD) is sensitive to deoxyhemoglobin providing information on tumor oxygenation. However, the measurements are affected by blood flow. This study explored the extent of flow sensitivity by comparing the BOLD signal intensity and T_2^* values with and without flow suppression using an orthotopic lung tumor model. T_2^* appeared to be insensitive to flow for the tumor regions as observed in this preliminary study, while semi-quantitative ΔSI was strongly affected by flow and is a potential caveat. For well vascularized normal tissue (such as liver), flow suppression will be necessary for accurate measurements.

4507

Computer 43

A probabilistic approach to automated classification of distinct pathological regions in soft tissue sarcoma using diffusion and T2 relaxation

Shu Xing^{1,2}, Carolyn Freeman³, Sungmi Jung⁴, and Ives Levesque^{1,2,5}

¹Physics, McGill University, Montreal, QC, Canada, ²Medical Physics Unit, McGill University, Montreal, QC, Canada, ³Radiation Oncology, McGill University Health Centre, Montreal, QC, Canada, ⁴Pathology, McGill University Health Centre, Montreal, QC, Canada, ⁵Research Institute of the McGill University Health Centre, Montreal, QC, Canada

In this work, we propose a novel probabilistic reference-region-based segmentation method to automatically distinguish various pathological tissue regions within soft tissue sarcoma, including high cellularity, high T2 and necrosis. The classification is based on a calculation of the probability that a tumour voxel belongs to a given class using the quantitative diffusion and T2 information when compared to a reference tissue. The probabilistic approach provides a more realistic classification of the complex tumour microenvironment compared to the previous proposed binary classification method.

4508

Computer 44

Microenvironmental changes in prostatic tissues in relation to tumor growth in low risk prostate cancer

Hugh Harvey¹, Veronica A Morgan¹, Christopher Parker², and Nandita M deSouza¹

¹CRUK Imaging Centre, The Institute of Cancer Research, Surrey, United Kingdom, ²Academic Urology Unit, The Royal Marsden Hospital NHS Foundation Trust, Sutton, United Kingdom

In 50 men with prostate cancer managed by active surveillance, changes in diffusion and perfusion within normal prostate and tumor were compared between those whose tumors did ("Growers") or did not grow. 14% had >50% increase in tumor volume on MRI at 1-year. In these men, ADC of normal PZ was lower and more homogenous and remained unchanged over time; vascular metrics also remained stable. In TZ, no changes occurred in ADC or vascular metrics. In tumor, K_{ep} increased with time in growers and ADC histogram metrics showed a left-shift indicating changes in tumor vascular and cellular microstructure with progression.

4509

Computer 45

Optimized Fast High-Resolution Whole-Body Imaging Protocols for Clinical Oncologic PET/MRI

Simone Angela Winkler¹, Anne Muehe¹, Ashok Theruvath¹, Maryam Aghighi¹, Sandra Luna-Fineman¹, Neyssa Marina¹, Ranjana Advani¹, Valentina Taviani², Samantha J Holdsworth¹, Praveen Gulaka¹, and Heike Daldrup-Link¹

¹Stanford University, Stanford, CA, United States, ²GE Healthcare

We present a fast sequence with high diagnostic accuracy to move towards high-throughput clinical whole-body cancer staging using PET/MRI. Ferumoxytol-contrast enhanced T1-weighted LAVA-Flex is acquired at 16s/bed, at a voxel size of 3.4x1.5x1.9mm. This contrast-enhanced sequence offers superior vessel contrast and resolution to existing T1 co-registration modalities that are most commonly based on MR attenuation correction sequences or longer T1-weighted sequences. Integration of this sequence in a clinical protocol bears the promise of dramatically accelerated whole-body cancer staging with durations <20min, thus offering similar exam times to the more radiation-invasive alternative of PET/CT.

4510

Computer 46

Localization of Subcortical Structures with the Presence of Lesions in Clinical Brain MRI

Long Xie^{1,2}, Yanhui Ding³, James C. Gee^{1,4,5}, Andreas M. Rauschecker⁴, and Jeffrey D. Rudie⁴

¹Penn Image Computing and Science Laboratory (PICSL), Department of Radiology, University of Pennsylvania, Philadelphia, PA, United States, ²Bioengineering, University of Pennsylvania, Philadelphia, PA, United States, ³School of Information Science and Engineering, Shandong Normal University, Jinan, People's Republic of China, ⁴Department of Radiology, University of Pennsylvania, Philadelphia, PA, United States, ⁵School of Computer Science & Engineering, University of Electronic Science and Technology of China, Chengdu, People's Republic of China

In this study, we proposed a pipeline to locate subcortical structures in patients with deep gray matter lesions using clinical brain MRI images. Due to altered signal intensity profile caused by lesions and high slice thickness (~5mm), segmentation of clinical MRI images provide challenges for state-of-the-art algorithms. Our proposed pipeline generates better subcortical structure segmentations, including better lesion coverage and more reliable segmentations than other widely used algorithms. The proposed pipeline may have help in automating the diagnosis of subcortical lesions, potentially improving current clinical practice.

Multi slice MRSI-based generation of nosological images of therapy response using a semi-supervised source extraction approach in preclinical glioblastoma.

Nuria Arias-Ramos^{1,2}, Silvia Lope-Piedrafita^{2,3}, Victor Mociou^{2,4}, Margarida Julià-Sapé^{1,2,4}, Carles Arús^{1,2,4}, and Ana Paula Candiota^{1,2,4}

¹Departament de Bioquímica i Biologia Molecular, Unitat de Bioquímica de Biociències, Universitat Autònoma de Barcelona, Cerdanyola del Vallès, Spain, ²Networking Research Center on Bioengineering, Biomaterials and Nanomedicine (CIBER-BBN), Cerdanyola del Vallès, Spain, ³Servei de Resonància Magnètica Nuclear, Universitat Autònoma de Barcelona, Cerdanyola del Vallès, Spain, ⁴Institut de Biotecnologia i de Biomedicina, Universitat Autònoma de Barcelona, Cerdanyola del Vallès, Spain

Glioblastoma (GBM) is the most common aggressive primary brain tumour in adults and characterization of response to treatment turns out to be crucial for improving patient survival. In this work we obtained 3D-like information, from preclinical GBM under temozolomide (TMZ) treatment, with a multi-slice MRSI approach using source-based nosological images as response biomarker. A "Tumour Response Index" (TRI) was defined as the percentage of responding tumor pixels divided by the total tumour pixels. Heterogeneous response patterns with cyclical longitudinal variations were observed in several mice while responding pixels were mostly seen at the first 2 upper grids.

Decreased apparent fibre density in an experimental model of traumatic brain injury

David K Wright^{1,2}, Leigh A Johnston^{2,3}, Jeff Kershaw⁴, Roger Ordidge⁵, Terence J O'Brien⁶, and Sandy R Shultz⁶

¹Department of Anatomy and Neuroscience, The University of Melbourne, Melbourne, Australia, ²The Florey Institute of Neuroscience and Mental Health, Parkville, Australia, ³Department of Electrical & Electronic Engineering, The University of Melbourne, Australia, ⁴National Institute of Radiological Sciences, Japan, ⁵Department of Anatomy and Neuroscience, The University of Melbourne, Australia, ⁶Department of Medicine, The University of Melbourne, Australia

Apparent fibre density (AFD) is postulated to be a sensitive marker of white matter damage and, as it is derived from a continuous fibre orientation distribution, may identify changes along single fibre bundles in regions containing multiple fibre groups. Here, we compared AFD to traditional DTI metrics in an experimental model of traumatic brain injury (TBI). We found that rats given a TBI had widespread regions of reduced AFD when compared to sham-injured rats as well as significant, but less extensive changes in DTI metrics. These results support the use of AFD in assessing disease progression and treatment following TBI.

Therapeutic Effect of Bone Marrow Stromal Cells on Vascular Permeability and Hemodynamic Alteration in Traumatic Injured Brain: A long-term MRI Study

Lian Li¹, Michael Chopp^{1,2}, Guangliang Ding¹, Changsheng Qu³, Qingjiang Li¹, Asim Mahmood³, and Quan Jiang^{1,2}

¹Neurology, Henry Ford Health System, Detroit, MI, United States, ²Physics, Oakland University, Rochester, MI, United States, ³Neurosurgery, Henry Ford Health System, Detroit, MI, United States

Cerebral vascular permeability and hemodynamic alteration in a broad normal appearing brain tissue in response to the transplantation of hMSCs after TBI were longitudinally investigated up to 3-months post-injury. Our data reveal the evidence that a quicker recovery of vascular integrity, as a result of cell transplantation, is associated with a higher level of cerebral perfusion, and acute cell administration after TBI significantly promotes these global therapeutic effects. The findings of the current study indicate that BBB reconstitution plays an essential role in CBF restoration in the injured brain, which in turn, contributes to the improvement of functional outcome.

Computer 3

Automated Versus Manual Analysis of DTI and Blood Flow in Adolescents with Chronic Post-Concussive Symptoms

Samuel Barnes¹, Brenda Bartnik-Olson¹, Holshouser Barbara¹, and Stephen Ashwal²

¹Radiology, Loma Linda University, Loma Linda, CA, United States, ²Pediatrics, Loma Linda University, Loma Linda, CA, United States

Adolescents who sustained a concussion and had persistent symptoms were scanned with DSC-PWI, to assess blood flow, and DTI. Images were compared with controls using automatically defined ROIs by registration to an atlas, and manually drawing ROIs. While both techniques showed similar trends manual ROIs has less variance within groups and therefore greater sensitivity. To detect subtle imaging changes after concussion on an individual basis, manual ROIs, despite being time intensive to define, should still be considered due to their greater sensitivity.

Computer 4

Reduced Brain Glutamine in Female Varsity Rugby Athletes after Concussion

Amy L Schranz^{1,2}, Kathryn Y Manning^{1,2}, Gregory A Dekaban^{3,4}, Lisa Fischer⁵, Kevin Blackney^{3,4}, Christy Barreira³, Tim Doherty⁶, Douglas Fraser⁷, Arthur Brown^{3,8}, Ravi S Menon^{1,2}, and Robert Bartha^{1,2}

¹Centre for Functional and Metabolic Mapping, Robarts Research Institute, London, ON, Canada, ²Medical Biophysics, University of Western Ontario, London, ON, Canada, ³Robarts Research Institute, London, ON, Canada, ⁴Microbiology and Immunology, University of Western Ontario, London, ON, Canada, ⁵Family Medicine and Fowler Kennedy Sport Medicine Clinic, University of Western Ontario, London, ON, Canada, ⁶Physical Medicine and Rehabilitation, University of Western Ontario, London, ON, Canada, ⁷Paediatrics Critical Care Medicine, London Health Sciences Centre, London, ON, Canada, ⁸Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada

The effect of concussion on female athletes is underreported in the literature. This study found reduced glutamine in the prefrontal white matter of female varsity rugby athletes after concussion and in non-concussed athletes after a season of play using proton magnetic resonance spectroscopy (MRS). Additionally, using diffusion tensor imaging, decreased fractional anisotropy and increased radial diffusivity were found within the spectroscopy voxel in athletes after a season of play. The observed changes were uncorrelated with clinical test scores suggesting these imaging metrics may be more sensitive to brain injury and could aid in concussion diagnosis and monitoring.

[Longitudinal Quantitative Susceptibility Changes after Mild Traumatic Brain Injury](#)

Kevin Koch¹, Robin Karr¹, Brad Swearingen², Ashley LaRoche², Casey Anderson¹, Timothy B Meier², Michael McCrea², and Andrew Nencka¹

¹Radiology, Medical College of Wisconsin, Milwaukee, WI, United States, ²Neurosurgery, Medical College of Wisconsin, Milwaukee, WI, United States

We present findings of longitudinal quantitative susceptibility mapping measurements on a cohort of contact sport athletes that were imaged longitudinally (24 hour, 8 day, 6 month) following diagnosed sport-related concussions (N=22). A cohort (N=29) of contact sport controls was imaged longitudinally using the same protocol and allowed stability assessment stability of the measurement. In regions of high stability, changes in susceptibility after injury were assessed in comparison to an atlas constructed from the control data. Substantial susceptibility variations after injury were found in the deep brain nuclei, which recovered and stabilized in the following two measurement points.

[Early NAA Reductions predict Neuropsychological Outcomes after Pediatric TBI](#)

Barbara Holshouser¹, Jamie Pivonka-Jones², Joy Nichols², Udo Oyoyo¹, Karen Tong¹, and Stephen Ashwal³

¹Radiology, Loma Linda University, Loma Linda, CA, United States, ²Pediatric Psychology, Loma Linda University, Loma Linda, CA, United States, ³Pediatric Neurology, Loma Linda University, Loma Linda, CA, United States

The primary aim of this prospective study was to test the hypothesis that early 3D MR spectroscopic (MRSI) changes in discrete regions of the brain after TBI predict neuropsychologic outcomes 1 year after injury. MRSI was acquired at 3T in 68 pediatric mild to severe TBI subjects and 72 controls. Subacute NAA/Cr and NAA/Cho ratios were significantly reduced in TBI patients in all brain regions. A binary logistic regression analysis using combined subcortical NAA/Cr ratios alone predicted dichotomized neurologic outcome (93%), Full Scale IQ (78%), General Memory (82%) and General Attention (88%).

[Mapping of endogenous glucose content on the detection of hypometabolic syndrome in experimental traumatic brain injury by glucoCEST](#)

Tsang-Wei Tu¹, Wael Ibrahim², Neekita Jikaria³, Dima Hammoud³, and Joseph Frank³

¹Radiology and Imaging Sciences, National Institutes of Health, Bethesda, MD, United States, ²National Library of Medicine, National Institutes of Health, ³Radiology and Imaging Sciences, National Institutes of Health

The current study investigated the feasibility of using glucoCEST technique, without delivering exogenous glucose as contrast agent, to measure the endogenous glucose content in brain by optimizing the saturation power and duration. The glucoCEST data were compared to the gold-standard ¹⁴C-2-deoxyglucose autoradiography for testing the sensitivity and specificity in the detection of hypometabolic syndrome in a rat model of diffuse traumatic brain injury (TBI). The glucoCEST showed comparable results to the 2DG-autoradiography showing glucose uptake largely decreased after TBI. Our findings suggest that glucoCEST could be a robust and reliable imaging modality capable of monitoring glucose metabolism non-invasively.

Increased cerebral level of GABA- in the acute phase of children's mild traumatic brain injury.

Petr Menshchikov^{1,2}, Tolibjon Akhadov², Olga Bozhko², and Natalia Semenova^{1,2}

¹Semenov Institute of Chemical Physics, Russian Academy of Sciences, Moscow, Russian Federation, ²Clinical and Research Institute of Urgent Pediatric Surgery and Trauma, Moscow, Russian Federation

There is not any information about [GABA] and [GABA]/[GLX] balance in human brain in acute phase of mTBI, but animal studies have shown alterations in concentrations of major inhibitory and excitatory neurotransmitters. [GABA-], [GABA+] and [GLX] were studied *in vivo* using MEGA-PRES pulse sequence in young patients (mean age - 16±2) with acute phase of mTBI. [GABA-]/[GLX] was significantly increased (p<0.05) in patients and [GABA-]/[tCr] had a trend for increase (p=0.09). This results correlates with animals experiments. [GABA+] didn't show any effects. Thus, [GABA-] MEGA-PRES is more preferable for accurate [GABA] estimation.

Computer 12

Increased regional cerebral venous oxygen saturation in mild traumatic brain injury is correlated with neurophysiological function: a magnetic susceptibility mapping study

Chao Chai¹, Chao Zuo², Linlin Fan, Tianyi Qian, E Mark Haacke, Shuang Xia, and Wen Shen

¹Radiology Department, Tianjin First Central Hospital, Tianjin, People's Republic of China, ²Department of Nuclear Medicine, Cangzhou Central Hospital

The aim of this study is to explore the changes of regional cerebral venous oxygen saturation (SvO₂) in patients with mild traumatic brain injury (mTBI) using susceptibility mapping (SWIM). SWIM was reconstructed from magnitude and phase data of SWI to measure the susceptibility of cerebral veins in mTBI patients and healthy controls. The results suggested that overall regional cerebral SvO₂ was higher in mTBI patients than controls. The regional cerebral SvO₂ shows that decreased to normal levels along with an increase in elapsed time post trauma and a high-SvO₂ condition is an evidence of neurophysiological deficit.

How strictly are traumatic microbleeds related to the actual diffuse axonal injury?

Arnold Toth¹, Balint Kornyei, Noemi Kovacs, Andras Buki, Tamas Doczi, Peter Bogner, and Attila Schwarcz

¹Department of Neurosurgery, University of Pécs, Pécs, Hungary

This study aims to reveal the relation between traumatic microbleeds (TMBs) on susceptibility weighted imaging and diffuse axonal injury (DAI). Regional TMB and diffusion tensor imaging (DTI) data were collected from 38 traumatic brain injury patients, and 20 control subjects. Analyses included multiple linear regression among TMB parameters, clinical variables and DTI data. Only basal ganglia area TMBs were found to be significantly related to DTI alteration indicating DAI. In general, TMBs might be rather due to microvascular vulnerability than actual DAI, however, specifically basal ganglia area TMBs might be still regarded as markers of DAI.

4529

[Quantitative Susceptibility Mapping of Hockey Players After Mild Traumatic Brain Injury](#)

Anna Pukropski¹, Alexander Weber¹, Michael Jarrett¹, Christian Kames², Shiroy Dadachanji, David K. B. Li³, Jack Taunton⁴, and Alexander Rauscher⁵

¹Pediatrics, University of British Columbia, Vancouver, BC, Canada, ²University of British Columbia, Vancouver, BC, Canada, ³Radiology, University of British Columbia, Vancouver, BC, Canada, ⁴Division of Sports Medicine, University of British Columbia, Vancouver, BC, Canada, ⁵Pediatrics, University of British Columbia, BC, Canada

We followed 45 varsity hockey players during one season of play, and scanned all players at the beginning of the season. 11 players received a concussion, and were scanned within 72hrs post-concussion, and then again after 2 weeks and 2 months. Quantitative Susceptibility Maps were created from the multi-echo 3D gradient-echo data, and susceptibility values were measured in deep grey matter (caudate, pallidum, putamen, and thalamus) and frontal and posterior WM in the corpus callosum (genu and splenium). A linear mixed-effect model analysis of the regions of interest revealed no significant changes over time compared to baseline.

4530

Computer 18

[Characterizing White Matter Microstructural Changes After Mild Traumatic Brain Injury Based On Diffusion White Matter Tract Integrity And Shannon Entropy](#)

Sohae Chung^{1,2}, Els Fieremans^{1,2}, Xiuyuan Wang^{1,2}, Dmitry S. Novikov^{1,2}, Farnq-Yang A. Foo³, Steven R. Flanagan⁴, and Yvonne W. Lui^{1,2}

¹Center for Advanced Imaging Innovation and Research (CAI2R), Department of Radiology, New York University School of Medicine, New York, NY, United States, ²Bernard and Irene Schwartz Center for Biomedical Imaging, Department of Radiology, New York University School of Medicine, New York, NY, United States, ³Department of Neurology, New York University Langone Medical Center, New York, NY, United States, ⁴Department of Rehabilitation Medicine, New York University Langone Medical Center, New York, NY, United States

Mild traumatic brain injury (MTBI) is a growing public health problem and some patients may suffer from long-term symptoms. This study shows that there are both microstructural changes as well as regional textural changes after MTBI affecting the corpus callosum within 4 weeks of injury. We demonstrate the potential for compartment specific white matter tract integrity (WMTI) metrics such as tortuosity of the extra-axonal space (a marker of misalignment of fibers or demyelination), and Shannon entropy (reflecting complexity or uncertainty) to be useful as early biomarkers of MTBI-related WM injury.

4531

Computer 19

[Identifying potential sites of brain injury in an individual concussed football player using a normative database based on diffusion kurtosis imaging](#)

L. Tugan Muftuler¹, Daniel V. Olson², and Michael A. McCrea¹

¹Department of Neurosurgery, Medical College of Wisconsin, Milwaukee, WI, United States, ²Department of Biophysics, Medical College of Wisconsin, Milwaukee, WI, United States

Mild traumatic brain injury (mTBI) is a prevalent health problem, especially in full-contact sports¹⁻⁶. Despite its prevalence, there is still a lack of reliable, unbiased biomarkers of brain injury and recovery following mTBI. Diffusion weighted MRI techniques have gained attention recently in studies of mTBI. Diffusion kurtosis tensor imaging (DKTI) is an extension of the conventional DTI, which estimates non-Gaussianity of bulk diffusion in each voxel. Our studies indicated that DKTI might be potential biomarker to detect subtle changes in brain tissues⁵. Here, we introduce a workflow to detect sites of brain injury in an individual concussed subject.

4532

Computer 20

[Measurements of Microstructural Changes after Sildenafil Treatment of Experimental Traumatic Brain Injury in Rats using Diffusion Tensor Imaging](#)

Asamoah Bosomtwi^{1,2}, Alexandru Korotcov^{1,2}, Angela Pronger³, Margalit Haber¹, Andrew Hoy^{2,3}, Ramon Diaz-Arrastia^{3,4}, and Bernard J Dardzinski^{2,3}

¹Center for Neuroscience and Regenerative Medicine, Henry Jackson Foundation, Bethesda, MD, United States, ²Radiology and Radiological Sciences, Uniformed Services University of Health Sciences, Bethesda, MD, United States, ³Center for Neuroscience and Regenerative Medicine, Uniformed Services University of Health Sciences, Bethesda, MD, United States, ⁴Neurology, Uniformed Services University of Health Sciences, Bethesda, MD, United States

The long-term dynamic response of microstructural changes in rat brain to the administration of sildenafil after traumatic brain injury (TBI) using non-invasive MRI techniques have been investigated. Our results demonstrate that the treatment of diffuse traumatic brain injury with sildenafil reverses several changes in brain microstructure at 30 days post injury. Diffusion tensor imaging (DTI) data suggests that sildenafil treatment improves white matter reorganization after TBI in rats compared with saline treatment.

4533

Computer 21

[Improved Anaplerotic Metabolism Following Sodium Pyruvate, Ethyl Pyruvate or Glucose Supplementation after Experimental Traumatic Brain Injury](#)

Brenda Bartnik Olson¹, Katsunori Shijo², Sima Ghavim², Neil Harris², and Richard Sutton²

¹Radiology, Loma Linda University, Loma Linda, CA, United States, ²Neurosurgery, David Geffen School of Medicine at UCLA

Traumatic brain injury initiates a cascade of events including increased oxidative stress that contributes to the period of generalized metabolic depression. Previously, sodium and ethyl pyruvate and glucose supplementation were shown to reduce cell death and improve recovery following experimental TBI. In this study we used ^{13}C NMR spectroscopy to determine if sodium pyruvate, ethyl pyruvate or glucose supplementation influences the activity of metabolic pathways associated with the intracellular redox state and oxidative metabolism. Our findings show improvements in astrocyte anaplerotic metabolism following all fuel treatments. Only animals treated with sodium pyruvate showed improved oxidative metabolism in neurons. None of the fuel treatments reduced the amount of glucose metabolized via the pentose phosphate pathway. The restoration of astrocyte metabolism by these fuels may partially underlie their abilities to improve cerebral glucose utilization and to reduce neuronal loss following experimental TBI.

4534

Computer 22

TBI Patients with Cerebral Microhemorrhage Exhibit Increased Magnetic Susceptibility in the Cerebral Hemispheres, but Reduced Magnetic Susceptibility in the Basal Ganglia

Wei Liu^{1,2}, Gerard Riedy¹, Ping-Hong Yeh^{1,2}, Dominic E. Nathan^{1,2}, Grant H. Bonavia¹, and John Ollinger¹

¹National Intrepid Center of Excellence, Walter Reed National Military Medical Center, Bethesda, MD, United States, ²The NorthTide Group, LLC, Dulles, VA, United States

Magnetic susceptibilities of the basal ganglia, as well as the right and left cerebral hemispheres of TBI patients with cerebral microhemorrhage (CMH) were analyzed. Compared to patients without CMH and controls, patients with CMH demonstrated increased magnetic susceptibility in both the left and right hemispheres but decreased magnetic susceptibility in the basal ganglia. This finding suggests disrupted brain iron homeostasis due to CMH in the chronic phase of TBI.

Longitudinal changes in cortical thickness in collegiate high contact sports

Maged Goubran¹, Sherveen Parivash¹, Paymon Rezaei¹, Wei Bian¹, Brian Boldt¹, Huy Do¹, David Douglas¹, Eugene Wilson¹, Lex Mitchell¹, Mansi Parekh¹, Scott Anderson¹, Gerald Grant¹, and Michael Zeineh¹

¹Stanford University, Stanford, CA, United States

There is emerging evidence that cumulative sports-related concussions may lead to long-term neurological abnormalities. The extent to which changes are occurring in collegiate athletes is still undetermined, and the progression of these changes is poorly understood. Cross sectional studies with small cohorts have found that concussions may be associated with cortical thinning in young football players^(1,2). We analyze the longitudinal changes occurring in high vs. low contact sports over the course of 3-4 years.

4536

Computer 24

Chronically elevated Taurine in the putative seizure onset zone during posttraumatic epileptogenesis identifies epilepsy-prone rats

Riikka Johanna Immonen¹, Amna Yasmin¹, Asla Pitkänen¹, and Olli Gröhn¹

¹Neurobiology, A.I. Virtanen Institute, Univ. Eastern Finland, Kuopio, Finland

In lateral fluid percussion rat model for posttraumatic epilepsy 50% of animals have slowly developed epilepsy 1 year after the head injury.¹ The seizures presumably originate in the perilesional cortex that appears normal in conventional MRI.² We targeted localized magnetic resonance spectroscopy (MRS) to this cortical area 6 months post-injury, and found elevated Taurine and elevated macromolecule concentration to differentiate the subpopulation (19%) of injured animals with higher susceptibility to seizures in EEG recorded PTZ test. The preliminary immunohistochemical analysis of the underlying complex pathology revealed swollen neurons that may associate with the increase of osmoregulator taurine.

Learning how to see the invisible - using machine learning to find underlying abnormality patterns in reportedly normal MR brain images from patients with epilepsy

Oscar Bennett¹, M. Jorge Cardoso¹, John Duncan^{2,3}, Gavin Winston^{2,3}, and Sebastien Ourselin¹

¹Translational Imaging Group, Centre for Medical Image Computing, University College London, London, United Kingdom, ²Department of Clinical and Experimental Epilepsy, UCL Institute of Neurology, London, United Kingdom, ³Epilepsy Society MRI Unit, Chalfont St Peter, United Kingdom

The visual identification of subtle abnormalities in MR brain images that underlie focal epilepsies is a challenging problem. In this study, we used machine learning techniques to uncover patterns of abnormality that exist within reportedly normal brain images from individuals with epilepsy. Our results demonstrated that abnormalities exist in MR images reported to be normal by a human reader, and that these abnormalities exist in a different spatial pattern to that seen in visually apparent cases. We obtained novel insights into why visual assessment may be ineffective in these visually normal cases and provide suggestions on how to improve this situation.

Computer 26

Water exchange in a white matter tissue phantom measured using clinically feasible diffusion exchange spectroscopy (DEXSY) MRI

Dan Benjamini¹, Michal E Komlos^{1,2}, and Peter J Basser¹

¹Quantitative Imaging and Tissue Sciences, National Institutes of Health, Bethesda, MD, United States, ²Center for Neuroscience and Regenerative Medicine, Bethesda, MD, United States

Studying the axons' membrane permeability at different white matter tracts could clarify the role of aquaporins. Diffusion exchange spectroscopy (DEXSY) is an assumption-free approach to measure water exchange, allowing for any number of exchange processes between any number of compartments. It has never been applied in biological MRI owing to its exceptionally long scan time requirements. Here we present a method to reduce the number of required acquisitions, making DEXSY-MRI clinically feasible for the first time. We apply this method on a nerve tissue phantom, and demonstrate that 14 acquisitions are sufficient to determine the exchange spectrum.

4539

Computer 27

The Anomalous Diffusion γ -parameter depends on local magnetic susceptibility differences when quantified in human brain tissue by MRI
Alessandra Caporale^{1,2}, Marco Palombo^{3,4}, Emiliano Macaluso⁵, Michele Guerrieri^{4,6}, Marco Bozzali⁷, and Silvia Capuani⁸

¹SAIMLAL Dept., Morpho-functional Sciences, Sapienza University of Rome, Rome, Italy, ²CNR ISC UOS Roma Sapienza, Rome, Italy, ³MIRCent, Commissariat à l'Energie Atomique, France, Italy, ⁴Physics Department, CNR ISC UOS Roma Sapienza, Rome, Italy, ⁵ImpAct Team, Lyon Neuroscience Research Center, Lyon, France, France, ⁶SAIMLAL Dept., Morphogenesis & Tissue Engineering, Sapienza University of Rome, Rome, Italy, ⁷NeuroImaging Laboratory, Santa Lucia Foundation, Rome, Italy, ⁸Physics Dept., CNR ISC UOS Roma Sapienza, Rome, Italy

Motivated by previous results obtained in vitro, we investigated the dependence of the anomalous diffusion γ -parameter on local magnetic susceptibility differences ($\Delta\chi$) in human brain. We performed diffusion weighted experiments varying diffusion gradient strengths in eight healthy subjects at 3.0T and measured the rate of relaxation ($R2^*$). We found significant strong linear correlations between γ and $R2^*$ both in white and gray matter selected regions. Conversely, DTI-parameters did not correlate with $R2^*$. Consequently AD- γ depends on $\Delta\chi$ due to differences in myelin orientation and iron content. This makes AD-imaging even more appealing for clinical neuroimaging investigations.

Single-scan, whole-brain functional network mapping using optogenetic fMRI with CBV

Andrew J Weitz¹, ManKin Choy², Ben A Duffy², Jia Liu², and Jin Hyung Lee^{1,2,3,4}

¹Bioengineering, Stanford University, Stanford, CA, United States, ²Neurology and Neurological Sciences, Stanford University, Stanford, CA, United States, ³Neurosurgery, Stanford University, Stanford, CA, United States, ⁴Electrical Engineering, Stanford University, Stanford, CA, United States

Optogenetic fMRI studies have traditionally required significant scan averaging to achieve signal-to-noise ratios sufficient for whole-brain functional network mapping. As a result, more scan time is required, and measurements may not directly translate to accompanying behavioral paradigms that employ a single stimulation. Here, we used a SPION-based MRI contrast agent to enable single-scan functional network mapping with CBV during optogenetic stimulation of the thalamic submedial nucleus. Measurement of CBV led to significant activations detected at the site of stimulation and downstream mono- and polysynaptically connected regions. In comparison, single-scan BOLD measurements led to minimal detectable responses to stimulation.

Advances in imaging the human brain with inhaled hyperpolarized xenon-129 MRI at 1.5 T

Madhwesha Rao¹, Neil Stewart¹, Paul Griffiths¹, Graham Norquay¹, and Jim Wild¹

¹University Of Sheffield, Sheffield, United Kingdom

The feasibility of imaging human brain *tissue-perfusion* using inhaled hyperpolarized ¹²⁹Xe magnetic resonance imaging is demonstrated. Enhancement of ¹²⁹Xe gas polarization and a custom brain RF coil array have together enabled imaging of hyperpolarized ¹²⁹Xe dissolved in the human brain at 1.5 T with a quality and signal-to-noise hitherto unseen. The images clearly demonstrate the uptake and washout of ¹²⁹Xe in the brain with time and could provide novel insights into cerebral perfusion and blood brain barrier permeability without the use of intravenous contrast.

4544

Computer 32

Interleaved pulse sequence for calibrated BOLD based on MRI measurement of venous oxygen saturation
Erin K Englund¹, Maria A Fernandez-Seara², Hyunyeol Lee¹, Zachary B Rodgers¹, John A Detre³, and Felix W Wehrli¹

¹Department of Radiology, University of Pennsylvania, Philadelphia, PA, United States, ²Department of Radiology, University of Navarra, Pamplona, Spain, ³Department of Neurology, University of Pennsylvania, Philadelphia, PA, United States

An improved interleaved pulse sequence termed "OxBOLD" is presented for calibrated fMRI. OxBOLD measures ASL-based perfusion and BOLD signal changes with whole-brain coverage, in addition to global measures of blood flow and venous oxygen saturation by concatenating background-suppressed 3D-GRASE pCASL, phase contrast, 2D-multi-slice EPI, and dual-echo GRE sequences. The OxBOLD pulse sequence is combined with the Y_v -based calibration model to derive the calibration factor, M , which relates perfusion and BOLD signal changes to the cerebral metabolic rate of oxygen ($CMRO_2$). M -maps derived from OxBOLD have similar M values averaged over grey matter as compared to the traditional Davis calibration model.

Advancing Quantitative Brain Injury Lesion Imaging Using Total Field Inversion QSM

Saill Soman¹, Zhe Liu², Ursula Nemec, Samantha Holdsworth, Keith L Main, Jerome Yesavage, David Hackney, Ansgar J Furst, Maheen M Adamson, Yi Wang, Pascal Spincemaille, and Michael Moseley

¹Radiology, Harvard Medical School / BIDMC, Boston, MA, United States, ²Cornell University

Traumatic brain injury often results in brain lesions which are subtle. Current conventional MRI techniques (GRE and SWI) are field strength and echo time dependent, causing lesions to possibly be missed. QSM methods can overcome this, but with many artifacts and missed lesions due to masking artifacts. TFI QSM can overcome this issue, as we demonstrate in this study of TBI patients.

4546

Improvement of dynamic improved motion-sensitized driven-equilibrium steady-state free precession (dynamic iMSDE SSFP) to visualize the irregular motion of cerebrospinal fluid

Tomohiko Horie¹, Nao Kajihara¹, Shuhei Shibukawa¹, Susumu Takano¹, Toshiki Saitou¹, Tetsu Niwa², Mitsunori Matsumae³, Kagayaki Kuroda⁴, Makoto Obara⁵, Tetsuo Ogino⁵, and Isao Muro⁶

¹Department of Radiology, Tokai University Hospital, Isehara, Japan, ²Department of Radiology, Tokai University School of Medicine, Isehara, Japan, ³Department of Neurosurgery, Tokai University School of Medicine, Isehara, Japan, ⁴Course of Electrical and Electronic Engineering, Graduate School of Engineering, Tokai University, Hiratsuka, Japan, ⁵Healthcare, Philips Electronics Japan Ltd, Shinagawa, Japan, ⁶Department of Radiology, Tokai University Hospital, Hachioji, Hachioji, Japan

We reported a new technique to visualize the irregular motion of cerebrospinal fluid (CSF) by using dynamic improved motion-sensitized driven-equilibrium steady-state free precession (dynamic iMSDE SSFP). The purpose of this study was to optimize the sequence parameters of dynamic iMSDE SSFP. As a result, the slow and irregular CSF motions were sensitively detected using the following parameters: T2prepTE: 30 ms, dynamic interval: 700 ms, flow VENC: 1 cm/s and the directions of MSG: 3axes. Therefore, optimized dynamic iMSDE SSFP is suggested to contribute to the diagnosis of various diseases in the CSF space.

Hybrid EEG and fMRI platform for multi-modal neurofeedback

Marsel Mano^{1,2}, Elise Bannier^{2,3}, Lorraine Perronnet^{1,2}, Anatole Lécuyer¹, and Christian Barillot^{2,4,5,6}

¹Hybrid Team, Inria, Rennes, France, ²VisAGeS Project-Team, Inria, Rennes, France, ³Service de Radiologie, CHU Pontchaillou, Rennes, France, ⁴VisAGeS U746, Inserm, Rennes, France, ⁵UMR CNRS 6074, IRISA, Rennes, France, ⁶University of Rennes, Rennes, France

Neurofeedback (NFB) relies on neurosignals for the estimation of brain activity. There exist a wide variety of NFB applications that use one type of neurosignals like fMRI or electroencephalography (EEG). Recently, the combination of two or more neurosignals has been receiving a lot of attention in the research community, but still very few multi-modal NFB applications exist. This is primarily because of the lack of commercial multi-modal NFB systems and the associated technical difficulties in building them.

Here we are going to describe a bi-modal EEG and fMRI NFB platform that we have build in our lab. Our platform is designed to maximize modularity and parallel processing in order to be able to provide real-time NFB with high level of synchronization and minimal delays. We have successfully used our platform to conduct over 100 uni-modal and bi-modal NFB experiments with more than 30 healthy subjects.

Pulsatility differences in large intracranial arteries and veins have been observed in patients with dementia using 4D flow MRI. How microvascular pulsatility is affected, however, is unclear. Non-invasive methods to monitor capillary pulsatility are still lacking. In this work, we present a method to assess brain parenchyma microvascular pulsatility using T2* signal changes over the cardiac cycle using ferumoxytol enhanced MRI. Significant differences in PI of the cortical gray matter were found when compared to white matter PI values. This method to assess microvascular blood volume pulsatility over the cardiac cycle might serve as a marker to study capillary pulsatility.

Hippocampal stiffness in mesial temporal sclerosis epilepsy measured by MR elastography: Initial results

Daniel R Smith¹, Hillary Schwarz², Ryan Pohlig³, William C Oliviero^{4,5}, Bradley P Sutton⁴, Tracey M Wszalek^{4,5}, Graham R Huesman^{4,5,6}, and Curtis L Johnson¹

¹Biomedical Engineering, University of Delaware, Newark, DE, United States, ²Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign, Urbana, IL, ³College of Health Sciences, University of Delaware, Newark, DE, United States, ⁴Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign, Urbana, IL, United States, ⁵Carle Neuroscience Institute, Carle Foundation Hospital, Urbana, IL, United States, ⁶Department of Molecular and Integrative Physiology, University of Illinois Urbana-Champaign, Urbana, IL, United States

Mesial temporal sclerosis (MTS), or hippocampal sclerosis, is the most common form of temporal lobe epilepsy and can be effectively treated by surgery if it is able to be reliably detected. In this work we examine whether hippocampal stiffness measured by magnetic resonance elastography (MRE) is sensitive to MTS. In our preliminary sample of five patients with MTS and seven controls, we found the hippocampus to be softer bilaterally in MTS (-13.4% and -15.2% differences for affected and unaffected sides). This preliminary evidence suggests MRE may provide highly sensitive markers that could aid the diagnosis and treatment of MTS.

A prior finding of robust cortical glutathione (GSH) deficits in patients with chronic fatigue syndrome (CFS) and major depressive disorder (MDD) provided a compelling rationale for this pilot study that aimed to assess whether 4 weeks of daily supplements of 1800mg of the GSH synthetic precursor N-acetylcysteine (NAC) would normalize brain GSH in CFS patients, as measured *in vivo* with J-edited MRS. The study's main finding was that NAC supplementation significantly increased cortical GSH levels in CFS patients compared to controls, while levels of the antioxidant remained statistically unchanged in controls despite a slight numerical increase.

T1 mapping from variable flip angle SPGR and IR-SPGR data using DESPOT1-HIFI

Mohammad Kayvanrad^{1,2}

¹Amirkabir University of Technology, Tehran, Iran, ²Robarts Research Institute, London, Canada

This work aims at improving the calculation of T1 maps at high magnetic fields from a set of VFA SPGR and IR-SPGR images for direct correction of B1 inhomogeneities using DESPOT1-HIFI. In the present work we (i) call attention to an erroneous assumption regarding the IR-SPGR signal intensity equation in the original DESPOT1-HIFI method and derive an alternative equation, and (ii) propose a reduced-dimensions least-squares fitting method, which turns the complex multi-parameter fitting into a simple one-dimensional search.

Ex-vivo Quantitative Susceptibility Mapping of Human Brain Hemispheres

Arnold M. Evia¹, Aikaterini Kotrotsou¹, Robert J. Dawe^{1,2,3}, Sue E. Leurgans^{2,4}, Julie A. Schneider^{2,4,5}, David A. Bennett^{2,4}, and Konstantinos Arfanakis^{1,2,3}

¹Department of Biomedical Engineering, Illinois Institute of Technology, Chicago, IL, United States, ²Rush Alzheimer's Disease Center, Rush University Medical Center, Chicago, IL, United States, ³Department of Diagnostic Radiology, Rush University Medical Center, Chicago, IL, United States, ⁴Department of Neurological Sciences, Rush University Medical Center, Chicago, IL, United States, ⁵Department of Pathology, Rush University Medical Center, Chicago, IL, United States

In order to establish the role of quantitative susceptibility mapping (QSM) as a diagnostic tool in aging, it is essential to combine QSM with direct assessments of age-related brain pathologies on the same individuals. Using ex-vivo QSM for this purpose may be more advantageous than in-vivo QSM, since ex-vivo QSM assesses the brain in the same condition as histology, and allows imaging of older adults independent of frailty level. However, being able to translate ex-vivo QSM findings to in-vivo is crucial. Therefore, our goal was to investigate the effects of death and fixation on brain QSM data collected ex-vivo.

Investigation of machine learning techniques in preoperative glioma grading based on multi-parametric MRI data

Xin Zhang¹, Linfeng Yan¹, Yang Yang¹, Haiyan Nan¹, Yu Han¹, Yuchuan Hu¹, Jin Zhang¹, Ying Yu¹, Yingzhi Sun¹, Qian Sun¹, Zhicheng Liu¹, Wen Wang¹, and Guangbin Cui¹

¹Department of Radiology, Tangdu Hospital, Fourth Military Medical University, Xi'an, People's Republic of China

This study demonstrates the significance of integrating multi-parametric MRI attributes and effective machine learning techniques in preoperative glioma grading. A comprehensive scheme combining tumor attribute extraction, attribute selection and classification model was proposed and tested. The tumor attributes were collected from histogram and texture analysis of multi-parameter MRI maps within the whole tumor. The classification performances of 25 commonly used classifiers combined with 8 kinds of attribute selection strategies in differentiating low grade gliomas from high grade gliomas were investigated. Support vector machine (SVM) combined with SVM-RFE attribute selection method were found to exhibit superior performance to others.

Quantitative and qualitative evaluation of "Flexible PET/MRI" images in brain

Mizue Suzuki¹, Yasutaka Fushimi¹, Tomohisa Okada², Takuya Hinoda¹, Ryusuke Nakamoto¹, Yuji Nakamoto¹, and Kaori Togashi¹

¹Department of Diagnostic Imaging and Nuclear Medicine, Kyoto University Graduate School of Medicine, Kyoto, Japan, ²Human Brain Research Center, Kyoto University Graduate School of Medicine, Kyoto, Japan

A newly developed "Flexible PET (fxPET)" is a prototype of MR-compatible mobile PET system. We tried to investigate the clinical feasibility of the fxPET with a 1.5T MRI compared with PET/CT for brain imaging. Twenty-one patients (including 12 patients with known intracranial masses) were enrolled in this study. We compared misregistration between fxPET/MRI and PET/CT, and compared the image quality of fxPET and PET in both qualitative (visual rating) and quantitative (standardized uptake value (SUV)-based analysis) manner. Consequently, fxPET/MRI showed acceptable misregistration and enough image quality, revealing clinical feasibility comparable to that of PET/CT.

MR Fingerprinting in paediatric neuroradiology: our initial experience

Graziella Donatelli¹, Guido Buonicontri², Rosa Pasquariello³, Mauro Costagli², Raffaello Canapicchi³, and Michela Tosetti^{2,3}

¹Università di Pisa, Pisa, Italy, ²IMAGO7 Research Institute, ³IRCCS Stella Maris, Pisa Italy

In paediatric neuroimaging, young children have often to be sedated in order to obtain diagnostic MRI images. Magnetic Resonance Fingerprinting (MRF) is a potential alternative to sedation in children, as it achieves a fast exam with reduced sensitivity to patient motion. MRF acquisitions can be used to acquire a fully-quantitative anatomical exam in less than five minutes at a standard resolution. We performed a preliminary evaluation of MRF in 15 paediatric patients, acquiring both the standard protocol and MRF at 1.5T. Detection of brain alterations was possible, if present, in all patients. Only a few small lesions were unrevealed. MRF could be a promising tool for a fast and diagnostic exam in children, and due to its low sensitivity to motion it has the potential to allow exams without sedation.

Computer 47

Contrast Agent-Induced High Signal Intensity in Dentate Nucleus on Unenhanced T1-Weighted Images: Comparison of Gadodiamide and Gadoxetic Acid

Shintaro Ichikawa¹, Utaroh Motosugi¹, Yoshie Omiya¹, and Hiroshi Onishi¹

¹Department of Radiology, University of Yamanashi, Chuo-shi, Japan

Hyperintensity in the dentate nucleus (DN) on unenhanced T1-weighted images was associated with previous administration of gadodiamide but not gadoxetic acid. There were no significant differences in DN-to-pons ratio between patients who received five or more administrations of gadoxetic acid and those without gadolinium-based contrast agent administration or chronic liver disease. Hyperintensity in the dentate nucleus on unenhanced T1-weighted images is not associated with up to fifteen previous administrations of gadoxetic acid. Therefore, gadolinium deposition in the brain might be difficult despite a history of repeated gadoxetic acid administration.

[In vivo measurement of water exchange at the human blood-cerebrospinal fluid barrier](#)Valerie C Anderson¹, Xin Li¹, Aaron Doud¹, Ian J Tagge¹, Eric M Baker¹, Joseph F Quinn², Jeffrey A Kaye², and William D Rooney¹

¹Advanced Imaging Research Center, Oregon Health & Science University, Portland, OR, United States, ²Dept. of Neurology, Oregon Health & Science University, Portland, OR, United States

Epithelial cells of the choroid plexus contain the blood-CSF barrier and play a pivotal role in brain water homeostasis. Here, DCE-MRI was used to investigate choroid plexus water exchange in 25 older individuals. A marked non-linearity of blood and tissue R_1 values was observed, indicating that water exchange departs the fast exchange limit at clinical blood contrast agent levels. Using a two-site model that explicitly incorporates water exchange between intra- and extraventricular compartments, a mean rate constant for ventricular water efflux, k_{10} , of $0.26 \pm 0.13 \text{ s}^{-1}$ was obtained. Significant associations of k_{10} with age and cognitive status were found.

[Evaluating brain tissue oxygen extraction fraction changes following transfusion therapy using TRUST MRI in adults with sickle cell anemia](#)
Meher R Juttukonda¹, Manus J Donahue¹, Melissa C Gindville², and Lori C Jordan²

¹Radiology and Radiological Sciences, Vanderbilt University Medical Center, Nashville, TN, United States, ²Pediatrics - Division of Pediatric Neurology, Vanderbilt University Medical Center, Nashville, TN, United States

Brain tissue oxygen extraction fraction (OEF) and cerebral blood flow (CBF) have been identified as potential imaging biomarkers for triaging adults with sickle cell anemia (SCA) for aggressive blood transfusion therapy for stroke prevention; however, little is known regarding how tissue-level hemodynamics are affected by transfusions. We utilized noninvasive MRI methods to assess OEF and CBF before and after transfusions in adults with SCA. Our results showed that OEF significantly reduces after transfusion and that this reduction parallels increases in blood oxygen content, while CBF is unchanged.

[Evaluation of hemodynamic impairments in healthy elderly participants and patients with high-grade unilateral carotid artery stenosis](#)Stephan Kaczmarz¹, Jens Götter¹, Vanessa Griese¹, Jan Petr², Kim van de Ven³, Michael Helle⁴, Hendrick Kooijman⁵, Anne Kluge⁶, Dimitrios C. Karampinos⁷, Claus Zimmer^{1,8}, Christian Sorg^{1,8}, and Christine Preibisch^{1,8,9}

¹Department of Neuroradiology, Technical University of Munich, Munich, Germany, ²PET center, Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany, ³Philips Healthcare, Best, Netherlands, ⁴Philips Research, Hamburg, Germany, ⁵Philips Healthcare, Hamburg, Germany, ⁶Department of Radiation Oncology and Radiotherapy, Charité Berlin, Berlin, Germany, ⁷Department of Radiology, Technical University of Munich, Munich, Germany, ⁸TUM Neuroimaging Center, Technical University of Munich, Munich, Germany, ⁹Clinic for Neurology, Technical University of Munich, Munich, Germany

Internal carotid-artery stenosis (ICAS) causes complex and not yet well understood physiological impairments. We present preliminary data from an ongoing clinical study in ICAS patients and healthy, age-matched participants. The major aims were to evaluate the reliability of a multimodal MRI-protocol and investigate physiological changes. For ICAS patients, regionally impaired vascular-reactivity as well as hypo-perfusion were found. In accordance with literature, we did not find ICAS-induced changes in oxygen extraction on group level. The presented preliminary results thus imply successful application of multimodal MRI methods and are highly promising with respect to gaining a deeper insight into ICAS-related physiological changes.

[The brain metabolite change of magnetic resonance spectroscopy for evaluating the Rehabilitation therapy effect of intra-cerebral hemorrhage rat animal model](#)Sang-Hun Jang¹ and Seung-Man Yu²

¹Gimcheon University, Gimcheon, Korea, Republic of, ²Gimcheon University, Gimcheon, Korea, Korea, Republic of

The objective of this study were to examine the brain metabolite concentration quantification change by in-vivo ¹H-MRS analysis in animal hemorrhage model, and we determined the bio-marker that was shown the effect of exercise treatment in hemorrhage disease. No significant difference in the concentration levels of experimental and control group were observed ($p=0.839$). There was great significance in revealing that (Glu+Gln)/tCr value was increased, and tCho/tCr concentration level was decrease applying exercise treatment methods on hemorrhage animal model. Therefore, the metabolite concentration change of (Glu+Gln)/tCr and tCho/tCr can be used as a powerful bio-marker that represented an exercise treatment in hemorrhage patients.

- Hemodynamic parameters such as wall shear stress(WSS) may be adversely affected in Sickle Cell Disease(SCD). Vaso-occlusion is a common complication leading to ischemic organ damage. We investigated how impaired hemodynamics (velocity, WSS, flow and lumen area) relate to ischemic white matter lesions(WMLs). Our aim was to quantify age-related changes in hemodynamics and to investigate their relationship with WMLs. 14 controls and 69 patients underwent 4D-flow MRI. We assessed intracranial velocity, WSS, flow and lumen area in the circle of Willis. We show that 4D-flow parameters are decreased in patients with WMLs, but age is an important factor in this relationship.

¹Center for BioMedical Imaging Research, Tsinghua, Beijing, People's Republic of China, ²Department of Image Center, Shanghai Xuhui Center Hospital, Shanghai, People's Republic of China, ³Department of radiology, University of Washington, Seattle, WA, United States
- Cerebral blood flow (CBF) reduction below a certain threshold is a main cause leading to cerebral ischemia. Arterial Spin Labeling (ASL) is a noncontrast MRI perfusion technique that can quantify CBF. Although ATA may be problematic for CBF quantification, there are evidences suggest that ATA may be a useful imaging biomarker to represent collateral flow and indicate better outcomes, this study aims to investigate the difference of ATA prevalence between stroke patients with cerebral artery stenosis and healthy volunteers. It was found that the stroke patients have more brain regions with long arterial transit time compared with healthy volunteers using a manual review method to estimate the overall CBF of subject while allowing ATA detection, suggesting ATA could be a potential imaging biomarker.

¹Beijing Institute for Brain Disorders, Capital Medical University, Beijing, People's Republic of China, ²Center for Biomedical Imaging Research, Department of Biomedical Engineering, Tsinghua University, Beijing, People's Republic of China, ³Department of Radiology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, People's Republic of China, ⁴Philips Research China, Philips Healthcare, Beijing, People's Republic of China, ⁵Department of Radiology, University of Washington, Seattle, United States
- Carotid artery severe stenosis or occlusion will lead to decreases in blood flow and ischemia in downstream arterial segments. It has been shown that ischemia within vessel wall may lead to wall edema which will affect the vascular revascularization after interventional treatment for the severe stenotic or occluded diseases. This study investigated the correlation between extra-cranial carotid artery stenotic diseases and arterial wall edema in ipsilateral petrous internal carotid artery (ICA) using 3D MR vessel wall imaging. We found that proximal ICA severe stenosis was independently associated with wall edema in ipsilateral petrous ICA (OR=2.45, 95% CI 1.65-3.63, P<0.001).
-
- 4569 **Computer 57** [Prevalence and Clinical Relevance of Intraplaque Haemorrhage in Stenotic and Non-stenotic Basilar Artery Intracranial Atherosclerotic Plaque](#)

 Chengcheng Zhu¹, Xia Tian², Andrew Degnan³, Zhongzhao Teng⁴, Jianping Lu², David Saloner¹, and Qi Liu²
¹Radiology, University of California, San Francisco, San Francisco, CA, United States, ²Radiology, Changhai Hospital, Shanghai, People's Republic of China, ³Radiology, University of Pittsburgh, PA, United States, ⁴Radiology, University of Cambridge, Cambridge, United Kingdom
- Intraplaque hemorrhage (IPH) in intracranial arteries is a possible marker of increased stroke risk. While previous studies focused on stenotic arteries, non-stenotic arteries also cause fatal stroke. We studied 100 patients using high-resolution MRI and found IPH was prevalent (>20%) in both stenotic and non-stenotic basilar arteries, and was a strong predictor of symptoms with an odd ratios of 15.4. IPH has a very high specificity (97.1%) to predict symptoms. Specifically, IPH may be useful in selecting high risk stroke patients with clinically non-significant stenosis, who may benefit from more aggressive treatment.

Sickle cell disease (SCD) is associated with chronic anaemia and oxygen desaturation, which elevates cerebral blood flow (CBF) and increases risk of stroke. Cerebral haemodynamics are abnormal and techniques for assessing CBF using a single inflow-time may not be sufficient. This study investigated haemodynamic parameters from a multi-inflow-time acquisition in younger and older children with SCD and healthy controls. CBF was elevated globally in both groups of patients, but in older children, patients had significantly shorter bolus arrival time. This may indicate increasing disparity between patients and controls with age and may be related to longer standing burden of disease.

4D Flow assessment of ophthalmic artery flow in patients with atherosclerotic internal carotid artery stenotic disease

Tetsuro Sekine¹, Ryo Takagi¹, Yasuo Amano^{1,2}, Yasuo Murai³, Yoshimitsu Fukushima¹, Erika Orita¹, Takahiro Andoh¹, Yoshio Matsumura³, and Shin-ichiro Kumita¹

¹Radiology, Nippon Medical School, Tokyo, Japan, ²Radiology, Nihon University School of Medicine, Tokyo, Japan, ³Neurosurgery, Nippon Medical School, Tokyo, Japan

We performed 4D Flow MRI assessment of the ophthalmic artery (OphA) flow in patients with internal carotid artery stenosis (ICS). Twenty-one consecutive patients with unilateral ICS were recruited. 4D Flow MRI and acetazolamide-stress brain perfusion SPECT were performed. The flow direction on the affected-side OphA was categorized into native flow and non-native flow based on 4D Flow MRI. In the affected-side MCA territory, the ratio of rest cerebral blood flow to normal control (RCBF_{MCA}) and cerebral vascular reserve (CVR_{MCA}) were calculated from SPECT dataset. Eleven patients had native OphA flow and the remaining 10 had non-native OphA flow. RCBF_{MCA} and CVR_{MCA} were significantly lower in non-native flow group (84.9±18.9% vs. 69.8±7.3%, p<0.05; 36.4±20.6% vs. 17.0±15.0%, p<0.05). Four patients in the non-native flow group and none in the native flow group were confirmed as high-risk (Sensitivity/Specificity, 1.00/0.65). The 6 min-standard 4D Flow MRI assessment of OphA in patients with ICS can predict intracranial hemodynamic impairment.

Computer 60

Slower Information Processing Speed is related to White-Matter Integrity in Sickle Cell Disease

Hanne Stotesbury¹, Fenella J Kirkham¹, Chris A Clark¹, and Jamie M Kawadler¹

¹Developmental Neurosciences, UCL Great Ormond Street Institute of Child Health, London, United Kingdom

Sickle cell disease (SCD) is associated with stroke¹ and slower processing². Slower processing in the absence of stroke may be related to hypoxic-ischaemic white-matter (WM) injury³. Cognitive assessments and tract-based spatial statistics analyses using diffusion tensor imaging (DTI), were conducted in 84 patients with SCD, stratified by degree of hypoxic-anaemic exposure. Processing speed indices (PSI) were related to WM integrity, and there were differences in PSI and WM integrity as a function of daytime oxygen-desaturation, but not SCI. The results provide links between oxygen desaturation, PSI, and WM integrity, and may indicate amelioration of function by interventions that reduce hypoxic exposure.

¹Academic Unit of Radiology, University of Sheffield, Sheffield, United Kingdom, ²Neuroimaging in Cardiovascular Disease (NICAD) Network, University of Sheffield, Sheffield, United Kingdom, ³Department of Psychology, University of Sheffield, Sheffield, United Kingdom, ⁴Academic Unit of Diabetes, University of Sheffield, Sheffield, United Kingdom

This study evaluates cerebral perfusion and cerebrovascular reserve (CVR) in impaired glucose tolerance and patients with type-2 diabetes using QUASAR Arterial Spin Labeling. CVR was evaluated as the change in gray matter CBF in response to a pharmacological stimulus. The developed processing pipeline was based on published QUASAR theory, modified to account for excessive motion and partial volume effects. Results show that baseline CBF is within the expected range. In patients with T2DM and IGT there is a significantly lower value of Cerebrovascular Reserve compared to healthy, normoglycaemic individuals.

4574

The use of Arterial Spin Labeling to Evaluate Posterior Circulation Ischemia in the elderly group (>80 years)

Rui Jia¹, Ningyu An², Xian Xu, and Bing Wu³

¹Department of Radiology, General Hospital of the People's Liberation Army, Beijing, People's Republic of China, ²General Hospital of the People's Liberation Army, ³GE Healthcare company

Contrast free arterial spin labeling approach is used to assess the perfusion changes in PCI in the elderly group (>80yrs) compared with normal control elderly group. Lower perfusion level was seen in PCI group, also a long PLD time is more effective in detecting the PCI group in case of slower perfusion rate. The lower level of increment with a long PLD in PCI group also indicates the weakened perfusion ability in the posterior circulation.

4575

Computer 63

Serial MRI of Lateral Ventricular Enlargement to Measure Rate of Brain Atrophy in Patients with Ischemic Stroke

Muhammad E. Haque¹, Refaat E. Gabr¹, Khader M Hasan¹, Jerome Jeevarajan¹, Jonathan Izygon¹, Duyen M Nghiem¹, Clark W Sittin¹, Ponnada A Narayana¹, and Sean I Savitz¹

¹UTHealth Science Center of Houston, Houston, TX, United States

The primary objective of this longitudinal study is to determine the rate of ipsilesional and contralesional lateral ventricular volume (LVv) enlargement in six mild chronic ischemic stroke patients who underwent serial brain MRI at four time points over one year. Infarct volumes, National Institutes of Health Stroke Scale (NIHSS), LVv, gray matter volume (GMv) and white matter volume (WMv) were also measured. Our results show the ipsilesional increase in LVv and the decrease in WMv suggests post-stroke progression of unilateral atrophy. These changes appear to be independent of the decrease in NIHSS during this same period. This study suggests that MRI can detect pathology that is not reflected by NIHSS.

Computer 65

The Sensorimotor Network Dysfunction in Migraineurs Without Aura: A Resting-state fMRI study

Jilei Zhang¹, Jingjing Su², Mengxing Wang¹, Qian Yao², Haifeng Lu¹, Hui Zhang¹, Jianqi Li¹, Jian-Ren Liu², and Xiaoxia Du^{1*}

¹Shanghai Key Laboratory of Magnetic Resonance and Department of Physics, School of Physics and Materials Science, East China Normal University, Shanghai, People's Republic of China, ²Department of Neurology and Jiuyuan Municipal Stroke Center, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, People's Republic of China

In current study, we analyzed resting-state fMRI data for the first time to evaluate the dysfunction of the sensorimotor network in migraineurs without aura by applying regional homogeneity (ReHo), amplitudes of low-frequency fluctuation (ALFF) and degree centrality (DC) analysis methods. The ReHo, DC and ALFF values were decreased in the S1 and PMC indicating the sensorimotor network dysfunction in migraineurs without aura. These changes may result in disruption of discrimination of sensory features of pain, thereby affecting nociception pathways. Non-invasive brain stimulation could be applied to sensorimotor network to modulate headache pain in future therapies.

Ischemic brain lesions and cognition in patients with aneurysmal subarachnoid hemorrhage.

Mariska E Hendriks¹, Irene MC Huenges-Wajer², Theo D Witkamp³, Jeroen Hendrikse⁴, Gabriel JE Rinkel⁴, Johanne MA Visser-Meily⁴, Mervyn DI Vergouwen⁴, and Jill B De Vis⁵

¹Radiology, University Medical Center Utrecht, Utrecht, Netherlands, ²Rehabilitation, University Medical Center Utrecht, ³University Medical Center Utrecht, Netherlands, ⁴University Medical Center Utrecht, ⁵Radiology, University Medical Center Utrecht, Washington, DC, United States

A significant amount of patients with aneurysmal subarachnoid hemorrhage suffer from cognitive impairment. The exact origin of this cognitive impairment is unclear. Lesions developing in relation to the event have been hypothesized as the mechanism of action. However, literature on this topic is inconclusive. We aimed to scrutinize this by analyzing our cohort of patients. Lesions were found in 60% of patients, no relation was found with cognitive outcome. This could be due to selection bias as most of the included patients had a good or mild impaired clinical status at admission and demonstrated 'no cognitive impairment' at follow-up.

Water Diffusion Heterogeneity in Cytoxic Edema

Kevin Midlash¹, Yong Jeong², Charles Cantrell², Keigo Kawaji¹, Greg Christoforidis¹, and Timothy J. Carroll¹

¹University of Chicago, Chicago, IL, United States, ²Northwestern, Evanston, IL, United States

Modern stroke research and treatment depend on the ability to accurately characterize and quantify diffusion volume. Current methods for segmentation and quantification of diffusion volumes are largely manual and time intensive. In this paper, we explored and validated a method of automatic segmentation of diffusion volumes. This algorithm was validated against known values from previous studies. We then studied the number of angles required to accurately predict diffusion volumes. We determined accurate volumes can be determined with as few as 3 directional vectors while accurate infarct mapping requires only 7 allowing for reduced scan time.

Sickle hemoglobin vs. normal hemoglobin: Any changes in susceptibility?

Cihat Eldeniz¹, Michael Binkley², Dustin K. Ragan³, Melanie Fields³, Kristin Guilliams³, Liam Comiskey³, Yasheng Chen³, Andria L Ford³, Jin-Moo Lee³, and Hongyu An¹

¹Mallinckrodt Institute of Radiology, Washington University in St. Louis, St. Louis, MO, United States, ²Washington University in St. Louis, St. Louis, MO, United States, ³Washington University in St. Louis

Alterations in cerebral oxygenation may be helpful as an imaging biomarker to predict stroke risk in sickle cell disease (SCD). Such measurement requires the knowledge of susceptibility properties of sickle hemoglobin, HbS. In this study, we aimed at measuring volume susceptibility difference between fully-oxygenated and full-deoxygenated blood, $\Delta\chi_0$, of HbS and HbA. The measured $\Delta\chi_0$ of HbA is consistent with literature reported range, and $\Delta\chi_0$ of HbS is greater than that of HbA. However, this difference does not reach statistical significance.

How does acute hypertensive crisis affect brain volume? A structural MRI study

Arzu Ceylan Has¹, Mehmet Yasir Pektezel², Mehmet Akif Topcuoglu², Rahsan Gocmen³, Bulent Erbil⁴, Nalan Metin Aksu⁴, Ethem Murat Arsava², and Kader K. Oguz³

¹National Magnetic Resonance Research Center (UMRAM), Ankara, Turkey, ²Department of Neurology, Faculty of Medicine, Hacettepe University, Ankara, Turkey, ³Department of Radiology, Faculty of Medicine, Hacettepe University, Ankara, Turkey, ⁴Department of Emergency Room, Faculty of Medicine, Hacettepe University, Ankara, Turkey

Acute elevations in systemic blood pressure can lead to a wide spectrum of central nervous system manifestations, including catastrophic scenarios like intracerebral hemorrhage. We hypothesized that brain swelling occurs in hypertensive crisis patients, assessed by structural MRI. We prospectively collected MRI data from a consecutive series of patients admitted to the emergency department with a diagnosis of hypertensive urgency but no neurologic symptoms. A second MRI was obtained at 3-months follow-up of blood pressure normalization. MRI analysis revealed reductions in cortical and sub-cortical gray matter after normalization of blood pressure.

Visualization of Post Stroke Revascularization on a Rat Model Using Dual R1- and Compressed Sensing Assisted R2*-MRAs
MungSoo Kang¹ and HyungJoon Cho¹

¹Department of Biomedical Engineering, Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of

The visualization of post stroke revascularization is of particular importance for the prognosis and therapeutic measures. In this work, using dual contrast R1-R2*-MRAs, visualization of post stroke revascularization on a rat model was performed. R1-R2*-MRAs were used to visualize surface and inner regions of rat brain, respectively. As a result of post stroke revascularization, all MRAs clearly showed thickened vessel structures in ipsilateral hemisphere.

The Value of High-resolution MRI and Perfusion Weighted Imaging in the Middle Cerebral Artery Atherosclerotic Stenosis
Shanshan Xie¹, Jingliang Cheng, Yong Zhang, and Chengru Song

¹The First Affiliated Hospital of Zhengzhou University, Zhengzhou, People's Republic of China

This study aimed to explore the assessment value of HRMRI and PWI in patients of TIA with unilateral MCA atherosclerotic stenosis. 43 patients with MCA territory symptoms underwent preliminary DWI and MRA to exclude acute cerebral infarction and ascertain unilateral stenosis of MCA M1 segment. Thereafter, all the patients underwent HRMRI and PWI. HRMRI gets 155 positive slices, type III of plaque 49 (31.6%), IV~V a 41 (26.5%), V b 4 (2.5%), VI 13 (8.4%), V c 48 (31.0%). The soft plaques (type IV~V a and VI) adds up to 54 (34.8%), hard plaques (type III, V b and V c) 101 (65.2%). HRMRI diagnosed four cases of mild stenosis, 11 moderate, 22 severe and 6 occlusion. 42 patients has hemisphere perfusion difference between the affected and normal MCA perfusion districts, with lower rCBF, longer rMTT and TTP (P <0.05) in the affected side. HRMRI can assess AHA sub-type and stability of atherosclerotic plaque, and stenosis rate of MCA, MTT, TTP can be found changes in early ischemic events, which are sensitive parameters to diagnose TIA.

NODDI revealed the brain microstructural damage in patients with moyamoya disease

Shoko Hara^{1,2}, Masaaki Hori¹, Syo Murata¹, Ryo Ueda¹, Misaki Nakazawa¹, Yoji Tanaka², Taketoshi Maehara², Shigeki Aoki¹, and Tadashi Nariai²

¹Department of Radiology, Juntendo University, Tokyo, Japan, ²Department of Neurosurgery, Tokyo Medical and Dental University, Tokyo, Japan

We applied Neurite Orientation Dispersion and Density Imaging (NODDI) and neurophysiological batteries to 13 patients with moyamoya disease (10 females, age 16-61 yo). We found that intracellular volume fraction (Vic) and orientation dispersion index (OD) decreased as the stages of vascular lesion progressed, and many neurocognitive tasks correlated with the decrease in Vic and OD among different parts of brain. Interestingly, some tasks were much more correlated with the Vic and OD among posterior part of brain than among frontal part. This finding may suggest the importance of PCA lesions in neurocognitive disturbance in patients with moyamoya disease.

In vivo evidence of negative fMRI response without decrease in neuronal activity: a combined optogenetic fMRI and electrophysiology study
Brittany Katz^{1,2,3}, Daniel Albaugh^{2,3,4}, Chunxiu Yu⁵, Martin J MacKinnon^{1,2}, Warren Grill⁵, and Yen Yu Ian Shih^{2,6}

¹Biomedical Research Imaging Center, University of North Carolina Chapel Hill, Chapel Hill, NC, United States, ²Neurology, University of North Carolina Chapel Hill, Chapel Hill, NC, United States, ³Neurobiology, University of North Carolina Chapel Hill, Chapel Hill, NC, United States, ⁴Biomedical Research Imaging Core, University of North Carolina Chapel Hill, Chapel Hill, NC, United States, ⁵Biomedical Engineering, Duke University, Durham, NC, United States, ⁶Biomedical Research Imaging Center, University of North Carolina Chapel Hill, Chapel Hill, NC, United States

Neurovascular coupling is the central principle of functional magnetic resonance imaging (fMRI), and thus critical for the interpretation of most fMRI data. While the strong majority of studies support such a tight coupling between neuronal and vascular activity changes in the cortex, the case may not be so straightforward in brain areas containing different cell types such as the striatum, wherein negative fMRI response has been observed to be positively correlated with 1, 2, or uncorrelated with electrophysiologically-measured neuronal activity^{3, 4}. Thus, the rodent striatum is an attractive platform to mechanistically dissect the rules governing neurovascular coupling, providing a novel case in which known coupling rules are violated. Taking this path, we began by asking a simple yet critical question: are neuronal activity increases in striatum causal in striatal negative fMRI response? Our results, employing an optogenetic-fMRI approach coupled with correlative in vivo electrophysiology, reveal that, indeed, selective excitation of striatal neurons drives large-scale local negative fMRI response. However, complementary electrophysiological data also described here suggests that the link between striatal neuronal activity and hemodynamics is more complicated than straightforward negative coupling

Abnormal resting-state functional connectivity of thalamus in patients with paroxysmal kinesigenic dyskinesia
Guangxiang Chen¹, Du Lei¹, Jiechuan Ren², Xiaoqi Huang¹, Dong Zhou², and Qiyong Gong¹

¹Huaxi MR Research Center (HMRR), Department of Radiology, West China Hospital, Sichuan University, Chengdu, People's Republic of China, ²Department of Neurology, West China Hospital, Sichuan University, Chengdu, People's Republic of China

The underlying pathophysiological mechanisms of paroxysmal kinesigenic dyskinesia are still not fully understood. The aim of this study was to investigate the patterns of resting-state functional connectivity of thalamus in patients with paroxysmal kinesigenic dyskinesia. Our novel findings of abnormal resting-state functional connectivity from thalamus to precentral gyrus and medial frontal gyrus provided direct evidence that the basal ganglia-thalamo-cortical circuit may play an important role in the pathogenesis of paroxysmal kinesigenic dyskinesia.

¹UCL Institute of Neurology, Queen Square MS Centre, University College London, London, United Kingdom, ²Department of Diagnostic Radiology, Faculty of Applied Medical Science, KAU, Jeddah, Saudi Arabia, ³Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics and Maternal and Child Health, University of Genoa, Genoa, Italy, ⁴Department of Brain and Behavioural Sciences, University of Pavia, Pavia, Italy, ⁵Brain Connectivity Centre, C. Mondino National Neurological Institute, Pavia, Italy, ⁶Wellcome Centre for Imaging Neuroscience, University College London, London, United Kingdom, ⁷Brain MRI 3T Mondino Research Center, C. Mondino National Neurological Institute, Pavia, Italy

We investigated linear and non-linear BOLD-grip force (GF) relationships in the brain using dominant (DH) and non-dominant hands (NDH). The NDH revealed widespread brain activations compared to DH, irrespective of GF. Looking at the BOLD-GF effects, both hands showed increased activations with increased GF within the contralateral M1 and ipsilateral anterior cerebellum. Non-linear BOLD-GF relationships (up to 4th order) were found, typically in posterior M1, premotor, sensory, parietal, and cerebellar areas. Finally, the consistent bilateral involvement of the cerebral and cerebellar areas suggests their involvement in error tracking or in synkinetic processes between DH and NDH.

Neural correlates of cognitive load on working memory in organic-solvent exposed brain using fMRI

Kyung Eun Jang¹, Jeehye Seo², Hyejeong Choi¹, Hyunsil Cha¹, Eunji Kim¹, Moojin Yang¹, Jiung Yang^{1,3}, Huijin Song², and Yongmin Chang^{1,4}

¹Medical & Biological Engineering, Kyungpook National University, Daegu, Korea, Republic of, ²Institute of Biomedical Engineering Research, Kyungpook National University, Daegu, Korea, Republic of, ³Daegu Kyungpook Medical Innovation Foundation, Daegu, Korea, Republic of, ⁴Radiology and Molecular Medicine, College of Medicine, Kyungpook National University, Daegu, Korea, Republic of

Several neuroimaging studies demonstrated that solvent-exposed subjects showed significantly poor performance on the working memory task than did controls [1,2]. However, no investigations have examined how solvent-exposed subjects are influenced by the cognitive load of a working memory task. Therefore, we performed N-back tasks with different cognitive demands using fMRI to investigate the neural basis for possible association between working memory load and memory deficit in the subjects with neurotoxicant solvent exposure. We found a positive correlation between response time of the 1-back task and percent BOLD signal changes in the left inferior parietal cortex, but a positive correlation was not founded of the 2-back task.

Obstructive sleep apnea (OSA) is a common and progressive condition that is accompanied by affective, cognitive and autonomic nervous system changes. Recent studies have demonstrated abnormalities in the brains of OSA subjects. However, no study has illustrated alterations in brain structural connectivity caused by OSA. To assess alterations of brain structural connectivity, we constructed a structural brain network from diffusion tensor imaging (DTI) and examined global network properties for control and OSA subjects. OSA subjects showed lower global efficiency, local efficiency and strength. Brain network analysis may improve understanding of global architecture of anatomical connection patterns in OSA.

An fMRI investigation of the neural efficiency of abstract reasoning as a function of trait anxiety

Shilpi Modi¹, Mukesh Kumar¹, Sanjeev Nara¹, and Subash Khushu¹

¹NMR Research Centre, INMAS, Delhi, India

According to the Attentional Control Theory, trait anxiety has a greater adverse effect on processing efficiency (i.e. performance effectiveness/effort) than on accuracy. Functional magnetic resonance imaging (fMRI) provides a measure of task-related effort in the form of neural activity elicited during cognitive processing. fMRI was used to assess the neural activation (Blood Oxygen Level Dependent (BOLD) contrast estimates) in a priori regions of interest for a reasoning task. Our results indicate that a compensatory increased neural effort is required by high trait anxious individuals to maintain an equivalent task performance as that of low anxiety individuals.

Altered resting state functional connectivity by autogenic training

Takashi Shizukuishi¹, Osamu Abe, Takahiro Shinozaki, Haruyasu Yamada, Akihiko Wada, Ryutaro Kohashi, and Yoshiki Imamura

¹Radiology, Nihon University School of Medicine, Tokyo, Japan

Objective: We investigated whether autogenic training (AT) altered resting state functional connectivity. **Methods:** 7 volunteers familiar with AT participated in this study. Rs-fMRI was performed pre and post AT, and 3D-T1WI was acquired. Group analysis was performed to explore the alteration of resting functional connectivity after autogenic training by using CONN functional connectivity toolbox. **Results:** Greater connectivity between 1. right amygdala and right caudate, 2. precuneus and left pallidum, and 3. right supratemporal gyrus and left pallidum, were demonstrated. **Conclusion:** AT could have positive effects not only to restore the automatic nervous system but also to alter RS functional connectivity.

Evidence of a link between brain structure and function and gut permeability: a combined RS-fMRI and DTI investigation of the brain-gut axis in healthy women

Suzanne T Witt¹, Olga Bednarska², Adriane Icenhour^{1,2}, Sigrid Eisenbruch³, Johan D Söderholm², Maria Engström^{1,4}, Emeran A Mayer⁵, Åsa Keita², and Susanna Walter^{1,2}

¹CMIV, Linköping University, Linköping, Sweden, ²Dept. of Clinical and Experimental Medicine, Linköping University, ³Institute of Medical Psychology & Behavioral Immunobiology, University of Duisburg-Essen, Essen, Germany, ⁴Dept. of Medical and Health Sciences, Linköping University, ⁵Dept. of Medicine, UCLA, Los Angeles, CA, United States

The brain-gut axis is thought to play a key role in the regulation of the gastrointestinal system with overall physical and emotional health. In diseases, such as irritable bowel syndrome, dysfunction within brain-gut interactions have been proposed to underlie symptoms of chronic abdominal pain. This study demonstrated that variations in gut mucosal permeability affected both resting-state functional connectivity in the DMN and white matter microstructure properties in healthy adult women. Variations within brain function and structure were apparent even when variations in gut permeability were small and remained within the normal range, indicating that brain-gut interactions may be quite sensitive.

Computer 85

Chronic exposure to air pollutants alters the functional network and spatiotemporal dynamics of the resting brain: Graph theory and dynamic functional connectivity analysis.

Suhnyoung Jun^{1,2}, Sanghoon Han^{1,2,3}, Chang Soo Kim^{2,4}, and Seung-Koo Lee^{2,5}

¹Psychology, Yonsei University, Seoul, Korea, Republic of, ²Integrative Neurocognitive Functional Imaging Center, Yonsei University, Seoul, Korea, Republic of, ³Cognitive Science Interdisciplinary Program, Yonsei University, Seoul, Korea, Republic of, ⁴Department of Preventive Medicine, Yonsei University, Seoul, Korea, Republic of, ⁵Radiology, Yonsei University, Seoul, Korea, Republic of

Detrimental effects of air pollutants on cognitive function are gaining considerable concern. The present study compared high-risk and low-risk group, defined based on the level of exposure to air pollutants, using graph theory-based approach and sliding window correlation analysis. Despite the undifferentiated cognitive functions between the groups, our study demonstrated the changes of the large-scale functional networks and dynamic brain activity of the high-risk group. Thus, our findings provide strong evidence of the influence of chronic high-dose exposure to air pollutants on the neural correlates, and offer new ways to understand the functional neural networks and dynamics.

Hope and the brain: trait hope mediates the protective role of the medial orbitofrontal cortex spontaneous activity against anxiety

Xin Xu^{1,2}, Song Wang¹, and Qiyong Gong¹

¹Huaxi MR Research Center (HMRR), Department of Radiology, West China Hospital of Sichuan University, Chengdu, People's Republic of China, ²Department of Psychiatry, West China Hospital of Sichuan University, Chengdu, People's Republic of China

As a personality trait, hope refers to the motivational tendency for initiating actions and generating routes to achieving goals and plays a protective role in anxiety. Here, we investigated the neural basis of hope in 231 adolescents using resting-state functional magnetic resonance imaging (RS-fMRI). We found that trait hope was negatively associated with the spontaneous activity in the bilateral medial orbitofrontal cortex (mOFC). Further mediation analyses revealed that trait hope mediated the relationship between the mOFC activity and trait anxiety. Taken Together, our findings might provide the initial evidence for the brain-personality mechanisms protecting against anxiety.

Computer 87

Improving attention through network-based neurofeedback training

Gustavo Pamplona¹, Frank Scharnowski², Yury Koush³, and Carlos Salmon¹

¹InBrain Lab, Department of Physics, Faculty of Philosophy, Sciences and Letters of Ribeirão Preto, University of São Paulo, Ribeirão Preto, SP, Brazil, ²Swiss Institute of Technology, University of Zürich, Zurich, Switzerland, ³Department of Radiology and Medical Imaging, Yale University, New Haven, CT, United States

Being able to sustain attention for longer without mind-wandering would improve our performance. The brain correlates underlying both sustained attention and mind-wandering – the so-called sustained attention and default mode networks, respectively – have been well identified. Nevertheless, this knowledge has not yet been translated in advanced brain-based attention training protocols. Here we propose to use a novel brain imaging technique based on real-time fMRI to provide participants with information about ongoing levels of activity. We thus propose a neurofeedback training of this difference between brain networks, what could lead to a boost in sustained attention ability, which is not reported yet.

Traffic-Related Air Pollution Associated with Activation in a Functional MRI Verb Generation Task of a Longitudinally Studied, Pediatric Cohort

Kim M Cecil¹, Thomas Maloney¹, Mekibib Altaye², Rachel Severs², Christopher Wolfe², Zana Percy³, Travis Beckwith¹, Kimberly Yolton², Grace LeMasters³, and Patrick Ryan²

¹Radiology/Imaging Research Center, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, ²Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, ³University of Cincinnati College of Medicine, Cincinnati, OH, United States

Traffic-related air pollution (TRAP) is strongly associated with adverse cardiopulmonary health effects. Evidence suggests the developing brain may also be a target organ for particulate matter due to translocation either from the respiratory system or through the olfactory nerve. Using a pediatric cohort, we tested the hypothesis that exposure to TRAP during critical windows of brain development is significantly associated with changes in brain functioning during a language task. Children with high exposure levels were associated with reduced activation within the frontal lobe compared with children at low exposure.

4601 Computer 89 Associations between clinical risk factors, neurocognitive performance and brain activity in survivors of childhood Acute Lymphoblastic Leukemia treated on a chemotherapy-only protocol

Slim Fellah¹, Matthew A. Scoggins¹, Ping Zou¹, Lisa M. Jacola², Ching-Hon Pui³, Robert J. Ogg¹, and Wilburn E. Reddick¹

¹Diagnostic Imaging, St Jude Children's Research Hospital, Memphis, TN, United States, ²Psychology, St Jude Children's Research Hospital, Memphis, TN, United States, ³Oncology, St Jude Children's Research Hospital, Memphis, TN, United States

ALL survivors treated with chemotherapy alone remain at elevated risk for neurocognitive impairment. We used fMRI to investigate associations between clinical risk factors, neurocognitive performance and brain activity in survivors of ALL. Ninety-two survivors completed Verbal and Object N-back tasks during fMRI at end of therapy. Measures of working memory were completed as part of a neurocognitive evaluation. Working memory-related brain activation was associated with important clinical risk factors and neurocognitive performance. The pattern of behavioral and imaging responses provides evidence for both compromised and compensatory changes in regional brain function. fMRI may help in selecting patients for remedial intervention.

4602 Computer 90 Low-frequency Visual Entrainment Enhances Bilateral Resting-state fMRI Connectivity in Primary Sensory Cortices

Eddie Wong^{1,2}, Celia M. Dong^{1,2}, Russell W. Chan^{1,2}, Leon C. Ho^{1,2}, Alex T. L. Leong^{1,2}, Condon Lau³, and Ed X. Wu^{1,2}

¹Laboratory of Biomedical Imaging and Signal Processing, The University of Hong Kong, Hong Kong, Hong Kong, ²Department of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, Hong Kong, ³Department of Physics and Materials Science, City University of Hong Kong, Hong Kong, Hong Kong

Entrainment is known to alter or synchronize brain rhythm and may enhance task performance. However, whether and how sensory entrainment may modulate the long-range brain functional networks are unknown. We investigated the effects of frequency-dependent visual entrainment on resting state functional connectivity in distinct sensory cortical networks. Our findings provide the first and direct evidence that only low frequency visual entrainment can modulate the long-range non-visual sensory networks. They suggest that the entrained neural oscillation at low frequency can actively contribute to the long-range interactions between primary sensory cortical functional networks that underlie the brainwide connectivity measured by resting-state fMRI.

4603 Computer 91 Disrupted Brain Connectivity Patterns in patients with Attention-deficit/hyperactivity disorder

Ming Zhou¹, Chuang Yang², Xuan Bu¹, Haixi Lin², Yan Liang², Lu Lu¹, Lianqing Zhang¹, Xinyu Hu¹, and Xiaoqi Huang¹

¹Department of Radiology, Huaxi MR Research Center, Chengdu, People's Republic of China, ²Department of Psychiatry, The First Affiliated Hospital of Wenzhou Medical University, People's Republic of China

In the current study, we used a graph theory-based network measurements named degree centrality (DC) to identify main cortical hubs in the brain network architecture at voxel level affected in ADHD. Then, functional connectivity maps were generated with seeded at altered DC to detect the brain changes at large-scale level. Finally, we found the disconnection within cortico-thalamus and cortico-striatal loops in ADHD patients, which may associated with inattention and cognitive function deficits.

4604 Computer 92 Neural mechanism of acupoint specificity underlying the antiemetic efficacy: an fMRI study.

Tong Yang¹ and Xuan Niu¹

¹The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, People's Republic of China

This paper presents an original research to investigate the underlying neural mechanism on acupoint specificity underlying the antiemetic efficacy. Our findings further suggested that acupuncture at different acupoints may exert distinct modulation effects on the brain activity patterns. Notably, we also may provide preliminary evidence for understanding the gut-brain communication.

4605 Computer 93 Changes in fMRI activation pattern during different levels of sacral nerve stimulation for overactive bladder

Pallab Bhattacharyya¹, Bradley Gill², Javier Pizarro-Berdichevsky^{2,3,4}, Howard Goldman², Mark Lowe¹, and Stephen Jones¹

¹Imaging Institute, Cleveland Clinic, Cleveland, OH, United States, ²Glickman Urology & Kidney Institute, Cleveland Clinic, Cleveland, OH, United States, ³Urogynecology Unit, H. Dr. Sotero del Rio, Santiago, Chile, ⁴Division Obstetricia y Ginecologia, Pontificia Universidad Católica de Chile

Sacral nerve stimulation (SNS) is an effective treatment for refractory overactive bladder(OAB). For patient-specific and therapeutic efficacy, stimulus at levels below or above the sensory level are sometimes applied on OAB patients. Previous functional brain studies suggested that few forebrain circuits acting primarily on midbrain periaqueductal grey is responsible for facilitating voiding reflex and a sensation of voiding. The neural circuits underlying the action of SNS, and its response to different levels of stimulus is studied by functional MRI (fMRI). Differences in activation patterns resulting from subsensory, sensory and suprasensory stimulation are reported.

Abnormal Brain Functional connectivity strength in the Absence of the Corpus Callosum: A Resting-State fMRI Study

Long Zuo¹, Shuangkun Wang, Hua Gu², Junliang Yuan², and Yang Zhou²

¹Beijing Chao-Yang hospital, Beijing, People's Republic of China, ²Beijing Chao-Yang hospital

The problem

The whole-brain functional connectivity strength on long-range and short-range in the AgCC is still unknown.

Methods

A novel voxel-based FCS analysis were performed on the whole-brain resting-state functional images.

Results

Compared with the healthy control subjects, the AgCC groups exhibits statistical differences of FCS on long-range and short-range connectivity respectively.

Conclusions

Anatomical distance affects functional connectivity strength in AgCC individuals.

Correlation of cerebrovascular reserve assessed by acetazolamide-stress SPECT with collaterals on arterial spin-labeling MRI in patients with carotid occlusive disease

Hyunkoo Kang¹ and Keuntak Roh¹

¹Department of Radiology, Seoul Veterans Hospital, Seoul, Korea, Republic of

We evaluated the correlation between cerebrovascular reserve (CVR) on acetazolamide-stress single photon emission computed tomography (SPECT) brain scans and collaterals on arterial spin-labeling (ASL) magnetic resonance imaging (MRI) in internal carotid artery (ICA) stenosis. With acetazolamide stress SPECT, the 21/74 (28%) patients showed evidence of decreased CVR. In 7/53 (13%) of the normal CVR group and 10/21 (48%) of the reduced CVR from the SPECT results, ASL showed ATA in ipsilateral to the stenosis. Significant relationship was observed between reduced CVR group and ATA showing group in ICA stenosis patients on ASL brain perfusion ($p=0.004$).

Differentiation of Intracerebral Hemorrhage from Ischemic Stroke at Early Stage Using a Novel Scheme of Length and Offset VARied Saturation (LOVARS) MRI

Yan Bai^{1,2}, Meiyun Wang¹, Yue Li³, Xiaowei He⁴, Xiaoyue Ma¹, Panli Zuo⁵, Yucheng Li¹, and Xiaolei Song²

¹Henan Provincial People's Hospital, Zhengzhou, People's Republic of China, ²The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ³AnatomyWorks LLC, Baltimore, MD, United States, ⁴Northwest University, Xi'an, People's Republic of China, ⁵Siemens Healthcare China, Beijing, People's Republic of China

This study investigated the diagnostic capability of a novel scheme of Length and Offset VARied Saturation (LOVARS) CEST method, for detecting and differentiating intracerebral hemorrhage from ischemic stroke at early stage. With the saturation offsets of 2 ppm and -3.5 ppm, the new LOVARS real image is able to separate ischemic lesion from hemorrhagic lesion by the opposite signal appearances for all patients enrolled. i.e. the former is hypointensity while the latter is hyperintensity. Our results revealed that the LOVARS real signals are significantly higher in hemorrhage than in ischemic stroke, which may serve as an imaging marker.

Measurement of mean transit time changes in response to Acetazolamide challenge in patients with cerebral steno-occlusive disease: a study using dynamic susceptibility contrast MR perfusion imaging.

Kyle Pate¹, Junjie Wu¹, Seena Dehkharghani², Fadi Nahab¹, Jason Allen, and Deqiang Qiu¹

¹Emory University, Atlanta, GA, United States, ²New York University

In this paper, 9 patients with chronic cerebrovascular disease underwent a two day MR perfusion study with a Diamox challenge in order to quantify cerebrovascular reserve with a focus on MTT and Tmax parameters. Parametric maps were generated and used to compare regional differences in four perfusion parameters between the left and right hemispheres, MCA and ACA vascular territories, and the cerebellum. This approach demonstrated an unexpected increase in MTT and Tmax augmentation in the anterior circulation over augmentation in the cerebellum.

Preliminary Study of High b-value Diffusion MRI for Characterizing White Matter Damage in A Mouse Model of Amyotrophic Lateral Sclerosis
Jin Gao¹, Rodolfo G Gatto², Richard Magin¹, Andrew C Larson³, and Weiguo Li^{1,3,4}

¹Bioengineering, University of Illinois at Chicago, Chicago, IL, United States, ²Anatomy and Cell Biology, University of Illinois at Chicago, Chicago, IL, United States, ³Radiology, Northwestern University, Chicago, IL, United States, ⁴Research Resource Center, University of Illinois at Chicago, Chicago, IL, United States

Amyotrophic lateral sclerosis (ALS), a progressive motor neuron disease, is characterized by severe cervical spinal cord damage caused by degeneration of the corticospinal tracts and loss of lower motor neurons. Although MR imaging of spinal cord is challenging, the ubiquity and non-invasive nature of MRI has supported its continued development and a leading role in ALS biomarker discovery. In this study, we investigated the feasibility of exploiting high b-value diffusion MRI to evaluate alterations of the spinal cord in a mouse model of ALS.

Quantitative Brain Oxygenation Measurements Made using Streamlined-qBOLD in Acute Stroke Patients: Further Investigation using a Detailed Voxel-Wise Analysis of Tissue Outcome

Alan J Stone¹, George WJ Harston², Davide Carone², Radim Licenik², James Kennedy², and Nicholas P Blockley¹

¹FMRIB, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom, ²Acute Vascular Imaging Centre and Acute Stroke Programme, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom

Streamlined-qBOLD is a baseline brain oxygenation measurement technique that has qualitatively shown promising results for the early identification of the ischaemic penumbra. Here regional definitions of tissue outcome are used to further investigate the application of this technique in acute stroke. Quantitative brain oxygenation parameters are demonstrated to vary between regions with different tissue outcomes.

Computer 102

A quantitative analysis using susceptibility mapping of unilateral middle cerebral artery thrombosis in patients with acute cerebral infarction
Shuang Xia¹, Chao Chai², Qingyuan Yang, Tianyi Qian, E Mark Haacke, and Wen Shen

¹Tianjin First Central Hospital, Tianjin, People's Republic of China, ²Radiology Department, Tianjin First Central Hospital, Tianjin, People's Republic of China

The aim of this study was to explore the correlation between thrombus length, thrombus susceptibility, CBS, DWI-ASPECTS, and admission and discharge NIHSS scores between patients with single-segment and multiple-segment thrombi using susceptibility mapping (SWIM). SWIM, reconstructed from magnitude and phase images acquired by an SWI sequence, was used to measure thrombus susceptibility in patients with acute infarction. A higher susceptibility of thrombus was correlated with lower DWI-ASPECTS and increased NIHSS scores. The patients with multiple-segment thrombi had a larger area of cerebral infarction, more severe symptoms, and worse clinical outcomes.

Computer 103

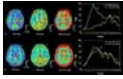

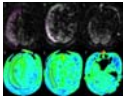

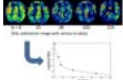

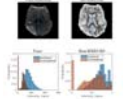

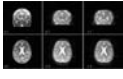

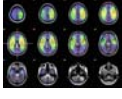

The potential of MRI as a biomarker in elderly patients with asymptomatic unilateral internal carotid artery stenosis

Pedro Henrique Rodrigues Silva¹, Ana Paula Afonso Camargo², André Monteiro Paschoal¹, Octavio M Pontes-Neto², and Renata Ferranti Leoni¹

¹Department of Physics, FFCLRP, University of Sao Paulo, Ribeirao Preto, Brazil, Ribeirão Preto, Brazil, ²Department of Neurosciences and Behavioral Science, FMRP, University of Sao Paulo, Ribeirao Preto, Brazil, Brazil

Asymptomatic unilateral internal carotid stenosis is associated with brain hemodynamic changes and cognitive impairment. However, the effects on Gray Matter (GM) volume, Cerebral Blood Flow (CBF) and Functional Connectivity (FC) are not clear. Therefore, the present study aims to assess changes in brain volume, CBF, resting-state FC and their relation to cognitive decline in a group of patients at presymptomatic stage using MRI. This study confirmed abnormalities in GM volume, CBF, RSNs and RS-FC in patients, showing that MRI have great potential as biomarker of the disease and may provide additional information to predict cases at risk of brain ischemia.

- 4616 **Computer 104** **Identifying Perfusion Deficit Patterns in Unilateral Middle Cerebral Artery Stenosis Patients using Multi-Inversion Time Arterial Spin Labeling**

 Shuang Yan¹, Tianyi Qian², Li Zhang³, Josef Pfeuffer⁴, Mingli Li¹, Bin Peng³, and Zhengyu Jin¹
¹Department of Radiology, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China, Beijing, People's Republic of China, ²Siemens Healthcare, MR Collaborations NE Asia, Beijing, China, ³Department of Neurology, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China, Beijing, People's Republic of China, ⁴Siemens Healthcare, ApplicationDevelopment, Erlangen, Germany
- To investigate the perfusion pattern in patients with unilateral middle cerebral artery stenosis, a multi-inversion time pulsed arterial spin labeling technique was used to measure the cerebral blood flow and bolus arrival time (BAT). The preliminary results indicate that patients with cerebral infarction (CI) had longer BAT than patients with transient ischemic attack (TIA). Assuming CBF values are corrected in the areas with BAT longer than 1300ms and combine the corrected CBF with the BAT, we can distinguish TIA and CI cases from their perfusion deficits patterns.
-
- 4617 **Computer 105** **Stable CBF fluctuation in 4-day follow up after carotid artery stenting compared with carotid endarterectomy revealed by 3D pCASL**

 Wang Ting¹, Xing Xinbo¹, Wu Bing², Ma Lin¹, and Lou Xin¹
¹Radiology, Chinese PLA General Hospital, Beijing, People's Republic of China, ²GE healthcare China
- Carotid endarterectomy (CEA) and carotid artery stenting (CAS) are two commonly used surgical treatment methods for severe internal carotid artery (ICA) stenosis, hence, our objective was to investigate the CBF difference before and in 4-day follow up after CEA and CAS using 3D pCASL technique. As it demonstrated, the CBF values showed no significant ($P > 0.05$) differences in various time points prior to the operations between CAS and CEA, whereas compared to the patients after CEA, the CBF values were stable fluctuated in various time points ($P < 0.05$). This proves that 3D pCASL is useful for quantifying CBF changes after CAS or CEA; moreover, the stable fluctuation CBF may indicate that CAS has a lower hyperperfusion syndrome and death rate compared to CEA in the future.
-

 Noriyuki Fujima¹, Tomoyuki Okuaki, Takuya Aoike, Suzuko Aoike, and Kohsuke Kudo
¹Hokkaido University Hospital, Sapporo, Japan
- Diffusion-weighted arterial spin labeling technique was described to depict the tissue water permeability in the brain non-invasively; this information was also described to reflect the degree of blood-brain barrier damage. This study revealed that tissue water permeability can be useful for the evaluation of ischemic lesion more in detail than conventional technique such as T2WI or FLAIR for the determination of severity of ischemia and the prediction how fast the ischemia will progress.
-
- 4619 **Computer 107** **Correlation of microstructure differences in diffusion MRI scans with Fugl-Meyer assessment scores in stroke subjects**

 Kyle Hodgson¹, Ganesh Adluru², Lorie Richards³, Jennifer Majersik⁴, and Edward DiBella⁵
¹Biomedical Engineering, University of Utah, Salt Lake City, UT, United States, ²Radiology and Imaging Sciences, University of Utah, ³Occupational Therapy, University of Utah, Salt Lake City, UT, United States, ⁴Neurology, University of Utah, ⁵Radiology and Imaging Sciences, Biomedical Engineering, University of Utah, Salt Lake City, UT, United States
- Improved characterization of brain microstructure is important for image-based methods for diagnosing stroke. We explored the extent to which microstructural maps including Fractional Anisotropy (FA), Generalized Fractional Anisotropy (GFA), and Neurite Orientation Dispersion Density Index (NODDI) detect ipsilateral and contralateral differences in stroke patients as a measure of stroke severity. The difference between hemispheres was correlated with Fugl-Meyer Assessment motor function scores and the results of 16 patient scans reported. Results suggest that the Orientation Dispersion Index (ODI) contains information that could be clinically useful in understanding stroke recovery.
-
- 4620 **Computer 108** **Clinical application of Half Fourier Acquisition Single Shot Turbo Spin Echo (HASTE) imaging with multiband (MB) excitation and PINS refocusing pulses**

¹Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen, Nijmegen, Netherlands, ²Department of Neurology, Radboud University Medical Centre, Nijmegen, Netherlands, ³Department of Radiology and Nuclear Medicine, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, ⁴Erwin L. Hahn Institute for Magnetic Resonance Imaging, University Duisburg-Essen, Essen, Germany
- In this abstract, we demonstrate a clinical application of a MB-PINS-HASTE sequence with TRAPS and compare it to a standard HASTE protocol which is used in daily clinical practice. The modified MB-PINS-HASTE sequence offers the possibility to overcome limitations related to its typically high energy deposition and can accelerate the acquisition by acquiring several slices simultaneously. The reconstructed images show good diagnostic quality for the evaluation of the overall brain and CSF spaces in patients with small vessel disease. MB-PINS HASTE therefore offers the possibility of using ultrafast spin-echo imaging to acquire anatomical T2-weighted images and follow dynamic signal changes.
-
- 4621 **Computer 109** **Voxel-based Lesion Mapping of Cardiogenic Cerebral Embolism**

 Masatoshi Takagaki¹, Yuki Togami¹, Akira Murasawa¹, Kazutami Nakao¹, and Manabu Kinoshita²
¹Neurosurgery, Kawachi general hospital, Higashi Osaka, Japan, ²Neurosurgery, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan

Although outcome of acute cardiogenic cerebral embolism patients improved dramatically due to development of interventional devices, sub-acute cases over the golden period still follow miserable clinical courses requiring to elucidate the pathology of cerebral ischemia. The authors attempted to unveil the correlation of clinical features following cardiogenic cerebral embolism and the locations or sizes of the infarction using voxel-based lesion mapping (VBLM). Our result revealed a correlation between spatial characteristics of infarction and clinical features. Larger ischemic volume at the left hemisphere is correlated with patient's outcome and cerebral herniation was strongly influenced by ischemic volume after standardization.

Computer 110

Correlating clinical outcome with voxel-based quantitative multiparametric MRI analysis in chronic ischemic stroke

Rui He^{1,2}, Olivier Detante^{2,3}, Alexandre Krainik^{2,3}, Assia Jaillard^{2,3}, Emmanuel Luc Barbier^{1,2}, and Benjamin Lemasson^{1,2}

¹U836, Inserm, Grenoble, France, ²Université Grenoble Alpes, Grenoble Institut des Neurosciences, Grenoble, France, ³Grenoble University Hospital, Grenoble, France

Predicting clinical outcome following stroke remains a challenge for magnetic resonance imaging (MRI). In this study, we acquired longitudinally (3 sessions) multiparametric MRI data sets including diffusion-weighted and perfusion-weighted images of 30 patients with chronic ischemic stroke. All of the diffusion and perfusion MRI parameters were analyzed by the classic whole-lesion approach and the parametric response map (PRM), a voxel-based post-processing approach at each time point. The results emphasized the superiority of the PRM over the whole-lesion approach for the prediction of long-term outcome based on early MRI data.

Magnetic particle imaging - The future of acute stroke imaging and treatment?

Peter Ludewig¹, Nadine Gdaniec², Jan Sedlacik³, Kannan M. Krishnan⁴, Christian Gerloff¹, Tobias Knopp², and Tim Magnus¹

¹Neurology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ²Institute of Biomedical Imaging, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ³Neuroradiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ⁴Materials Science and Engineering Department, University of Washington, Seattle, United States

Magnetic particle imaging (MPI) is a new tomographic imaging modality with superior temporal and spatial resolution compared to other imaging techniques, allowing 3D real-time assessment of vasculature and perfusion without X-rays or nephrotoxic contrast agents. For the first time we show that MPI can be used for the diagnosis of acute pathologies like ischemic stroke by showing the first MPI stroke images in a murine stroke model. Additionally, we give an outlook how MPI may revolutionize not only stroke imaging but also stroke treatment, as the magnetic fields of the MPI can be used for catheter guidance and targeted drug delivery.

Decreased borderzone perfusion is related to brain parenchymal volume loss after subarachnoid hemorrhage

Lisa A. van der Kleij¹, Carlo Lucci¹, Esben T. Petersen², Mervyn D.I. Vergouwen³, Gabriel J.E. Rinkel³, Jeroen Hendrikse¹, and Jill B. De Vis¹

¹Department of Radiology, University Medical Center Utrecht, Utrecht, Netherlands, ²Danish Research Centre for Magnetic Resonance, Copenhagen University Hospital Hvidovre, Denmark, ³Department of Neurology and Neurosurgery, Brain Center Rudolf Magnus, University Medical Center Utrecht, Netherlands

Brain injury after aneurysmal subarachnoid hemorrhage (aSAH) has been linked to cerebral hypoperfusion in the acute and subacute disease stage. The areas most prone to hypoperfusion are the borderzone regions. In this study we obtained cerebral blood flow measurements in the subacute stage after aSAH, and longitudinal volumetric data. We found a moderate correlation between the ratio of borderzone/whole-brain perfusion and percentage brain volume loss. Thereby, perfusion in the watershed areas in the subacute stage could identify patients at a higher risk for future brain parenchymal volume loss. Consequently, increasing perfusion in these regions could be a future therapeutic target.

¹Medical Imaging, National Taiwan University Hospital, Taipei, Taiwan, ²Neurology, National Taiwan University Hospital, Taipei, Taiwan, ³Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan, ⁴Radiology, Cathay General Hospital, Taipei, Taiwan, ⁵Graduate Institute of Oncology, National Taiwan University, Taipei, Taiwan, ⁶Graduate Institute of Clinical Medicine, National Taiwan University, Taipei, Taiwan

Internal carotid artery stenosis (ICAS) has been identified as a risk factor of ischemic stroke, with altered flow velocity and narrowed lumen commonly assessed by ultrasonography and angiography. However, hemodynamic change/compensation in microvasculature cannot be ruled out before symptoms. In this study, we investigated cerebral perfusion changes in asymptomatic ICAS by simultaneously assessing cerebral blood flow (CBF), arterial transit time (ATT), and flow territory, derived from arterial spin-labeling (ASL) MRI. Our data suggest that ATT and flow territory may be better predictors of high-grade unilateral ICA stenosis ($\geq 70\%$) than CBF in asymptomatic patients.

¹Department of Electrical Engineering, University of Southern California, Los Angeles, CA, United States, ²Department of Biomedical Engineering, University of Southern California, Los Angeles, CA, United States, ³Radiology, Children's Hospital of Los Angeles, Los Angeles, CA, United States, ⁴Section of Hematology, Children's Hospital of Los Angeles, Los Angeles, CA, United States, ⁵Division of Cardiology, Children's Hospital of Los Angeles, Los Angeles, CA, United States

Sickle cell disease (SCD) is a genetic blood disorder with a high prevalence of cerebral vasculopathy and stroke. Arterial Transit Time (ATT) refers to the time it takes blood to flow from the labeling plane, to the vascular imaging compartment and reflects cerebrovascular impairment in SCD. We used pseudo continuous arterial spin labeling to measure ATT with flow encoding arterial spin tagging technique in patients with SCD and ethnicity matched, healthy controls. Our findings demonstrated sensitivity of ATT to vasculopathy.

¹Department of Radiology and Neuroradiology, UKSH, Kiel, Germany, ²Department of Experimental and Clinical Pharmacology, UKSH, Kiel, Germany, ³Research Laboratories, Philips GmbH Innovative Technologies, Hamburg, Germany

Electric properties tomography (EPT) is a new contrast in MRI which delivers information on tissue electrical conductivity. Up to now, it has been mostly used for tumor mapping. Ischemic cerebral stroke is another promising application. Seven male Wistar rats were used in this study. Five culled animals from another stroke study, three of which were subjected to MCAO and two live animals which were also subjected to MCAO were examined. Healthy cortical grey matter, white matter and cerebrospinal fluid could be well differentiated Conductivity was altered within the infarct. EPT is feasible in a rodent model of stroke.

Quantitative Susceptibility Mapping of Intracranial Hemorrhage: Time Evolution and Comparison to CT

Hongfu Sun^{1,2}, Derek J. Emery³, Kenneth Butcher⁴, and Alan H. Wilman²

¹Radiology, University of Calgary, Calgary, AB, Canada, ²Biomedical Engineering, University of Alberta, Edmonton, AB, Canada, ³Radiology and Diagnostic Imaging, University of Alberta, Edmonton, AB, Canada, ⁴Division of Neurology, Department of Medicine, University of Alberta, Edmonton, AB, Canada

To follow the time evolution of intracranial hemorrhage (ICH) using quantitative susceptibility mapping (QSM) and compare to CT. Twenty ICH patients were followed using a clinical MRI protocol typically performed on day 2, 7 and 30. The ICH areas and mean values were compared between the CT and QSM on 18 patients (average 1.7 days apart). Time evolution of ICH was also investigated by QSM. In conclusion, QSM can be used to measure the size of ICH and track susceptibility evolution of the blood degradation products, providing a means to track iron evolution.

BRAIN PARENCHYMAL VOLUME CHANGES AFTER ANEURYSMAL SUBARACHNOID HEMORRHAGE

Carlo Lucci¹, Lisa A. van der Kleij¹, Mervyn D.I. Vergouwen², Gabriël J.E. Rinkel², Jeroen Hendriks¹, and Jill B. De Vis¹

¹Department of Radiology, University Medical Center Utrecht, Utrecht, Netherlands, ²Department of Neurology and Neurosurgery, Brain Center Rudolf Magnus, University Medical Center Utrecht, Netherlands

Aneurysmal Subarachnoid Hemorrhage (aSAH) accounts for only 5% of all strokes, but it is a disabling disease because of the cognitive deficits that occur in many survivors. We hypothesize these deficits to be caused by an accelerated brain atrophy process that develops after the event. To investigate this hypothesis, we evaluated brain volume changes in aSAH patients over time.

4632

2-deoxy-D-glucose-conjugated magnetonanoparticles (2DG-MNP) uptake as a measure of metabolic activity in glioblastoma murine model
Jelena Lazovic¹, Whitney Pope², and Massoud Akhtari

¹preclinical imaging, Vienna Biocenter Core Facilities, Vienna, Austria, ²Radiology, University of California, Los Angeles, CA, United States

In the current study we tested if accumulation of non-radioactive 2-deoxy-D-glucose (2DG)-conjugated magnetonanoparticles (2DG-MNP) can be used as a measure of metabolic activity in glioblastoma. To quantify 2DG-MNP uptake across brain ΔR_2 maps are proposed. The difference in R_2 relaxation rates prior to and at different times following 2DG- or unlabeled (plain) MNP administration represents ΔR_2 . Significant changes in ΔR_2 between brain and glioblastoma, reflecting increased metabolic rate of glioblastoma were found for glucose labeled MNP and not for plain-MNP. Our results suggest that 2DG-MNP have potential to be utilized in metabolic imaging as non-radioactive 2-¹⁸F]-fluoro-deoxy-D-glucose analogue.

Regional GABA concentrations modulate inter-network resting-state functional connectivity
Xi Chen¹, Xiaoying Fan¹, Yuzheng Hu², Chun Zuo¹, Dost Ongur¹, and Fei Du¹

¹McLean Hospital, Belmont, MA, United States, ²National Institute on Drug Abuse, Baltimore, MD, United States

The resting-state functional connectivity (rsFC) and task evoked fMRI, involving the default mode network (DMN) and control network (CN) was performed, with GABA, glutamate and glutamine measured at MPFC and DLPFC, in order to explore the underlying molecular mechanism of the DMN-CN interaction. We found that MPFC GABA concentrations significantly modulate DMN deactivation during a working memory task, and resting state anti-correlation between DMN and CN, while DLPFC GABA correlations modulate DMN-CN anti-correlation in the opposite direction. These findings suggest that MPFC and DLPFC GABA make a major but differential impact on task related activation and inter-network rsFC. The neurochemical characteristics of DMN and CN may provide novel insights into abnormal network activity in neuropsychiatric diseases and provide opportunities for novel interventions.

Sleep-Disordered Breathing Severity in Elderly is Associated with Decreased GABA in the Dorsolateral Prefrontal Cortex: A J-edited 1H MRS and Polysomnography Study

Ana C Pereira¹, Xiangling Mao², Caroline S Jiang³, Guoxin Kang², SAra Milrad⁴, Bruce S McEwen³, Ana C Krieger⁴, and Dikoma C. Shungu⁵

¹Laboratory of Neuroendocrinology, The Rockefeller University, New York, NY, United States, ²Radiology, Weill Cornell Medicine, ³Laboratory of Neuroendocrinology, The Rockefeller University, ⁴Medicine, Neurology and Neuroscience, Weill Cornell Medicine, ⁵Radiology, Weill Cornell Medicine, New York, NY, United States

Sleep-disordered breathing (SDB) is a disorder characterized by repeated episodes of hypopnea and apnea during sleep that lead to sleep fragmentation and intermittent hypoxia. A leading model of model of SDB that posits GABAergic and glutamatergic dysregulations that lead to hyperexcitability and neuronal damage, which this study aimed to investigate using J-edited MRS and polysomnography. The main results were a robust DLPFC GABA decrease and associations between GABA and hypoxia as well as disease severity. The state of hyperexcitability observed in SDB is interpreted as likely the result of disinhibition (GABA) that might lead to excitotoxicity and neuronal damage.

MR Imaging & Spectroscopy in a Non-Human Primate Model of Ebola Makona Aerosol Exposure

Margaret R Lentz¹, Anna N Honko¹, Jordan K Bohannon¹, Matthew G Lackemeyer¹, Jeffrey M Solomon², Louis M Huzella¹, Gene G Olinger¹, Lisa E Hensley¹, and Peter B Jahrling^{1,3}

¹NIAID/Integrated Research Facility, National Institutes of Health, Frederick, MD, United States, ²Clinical Research Directorate & Clinical Monitoring Research Program, Leidos Biomedical Research, Inc., Frederick, MD, United States, ³NIAID, Emerging Viral Pathogens Section, National Institutes of Health, Frederick, MD, United States

The purpose of this study was to use MRI and magnetic resonance spectroscopy (MRS) to determine if structural or metabolic alterations occur in the brain of rhesus macaques exposed to Ebola virus via inhalation of aerosolized small particles. Unlike intramuscular inoculation with Ebola virus, small-particle aerosol exposure of macaques did not result in uniform changes in brain volume or vascular alterations 8-9 days after exposure. However, most animals had reductions in N-acetyl aspartate and increases in choline levels, indicating spectroscopy may be useful in identifying early alterations in brain metabolism due to Ebola virus disease.

The impact of inflammation on grey matter metabolism, quantified using a novel NIRS/MRI system

Thomas Wade Johnson¹, James A Rogers², and Jeff F Dunn¹

¹Radiology, University of Calgary, Cumming School of Medicine, Calgary, AB, Canada, ²Clinical Neurosciences, University of Calgary, Cumming School of Medicine, Calgary, AB, Canada

Cerebral metabolic rate for oxygen (CMRO₂) in gray matter (GM) is a sensitive marker for abnormalities in oxidative metabolism. We combined a near-infrared spectroscopy (NIRS) system with 9.4.T MRI to quantify regional CMRO₂ in the experimental autoimmune encephalomyelitis (EAE) mouse model of multiple sclerosis. Increases in CMRO₂ were seen in EAE mice and positive inflammation (CFA) controls at day 35 post-induction when compared to naïve controls. In addition, EAE and CFA mice showed increased CMRO₂ from day 14 to 35. These data indicate that inflammation alone, not necessarily linked to a white matter autoimmune disease, could cause abnormal CMRO₂ in GM.

Individual mapping of neuronal damage in early relapsing-remitting MS using [11C]Flumazenil PET

Emilie Poirion^{1,2}, Benedetta Bodini¹, Marco Battaglini³, Theodore Soulier¹, Léorah Freeman¹, Daniel Lorenzo-Garcia¹, Géraldine Bera¹, Michel Bottlaender⁴, and Bruno Stankoff¹

¹Institut du Cerveau et de la Moelle Epinière/CNRS UMR 7225/INSERM 1127/UPMC UM75, Paris, France, Paris, France, ²CEA, DRF, I2BM, Neurospin, UNIRS, Paris, France, ³tement of medicine, Surgery and Neuroscience, University of Siena, Siena, Italy, Italy, ⁴CEA, DRF, I2BM, Neurospin, UNIACT, Paris, France

We explored the neuronal component of grey matter damage in the earliest phase of multiple sclerosis (MS) with [11C]Flumazenil positron emission tomography (PET). Using a novel post-processing approach based on the generation of individual maps of neuronal pathology, we found a significant neuronal damage in the cortical lesions of patients with MS which preceded the occurrence of cortical atrophy, and correlated with white matter lesion load. These results suggest that cortical demyelination, together with retrograde degeneration of transected axons within white matter lesions, are among the key pathogenic contributors to neuronal cortical damage at the earliest stage of the disease.

MRS-based classification of Spinocerebellar Ataxias 1, 2, 3, and 6 at 7T: A distance-weighted discrimination approach

James Joers¹, Dinesh Deelchand¹, Tianmeng Lyu², Uzay Emir^{1,3}, Diane Hutter¹, Christopher M Gomez⁴, Khalaf O Bushara⁵, Lynn E. Eberly², and Gulin Oz¹

¹Center for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN, United States, ²Division of Biostatistics, University of Minnesota, Minneapolis, MN, United States, ³University of Oxford, Oxford, United Kingdom, ⁴Department of Neurology, University of Chicago, Chicago, IL, ⁵Department of Neurology, University of Minnesota, Minneapolis, MN

We investigated the sensitivity of ultra-high field MRS to distinguish 4 hereditary neurodegenerative diseases with substantial overlap in clinical presentation and conventional MRI. We carried out pairwise classifications of spinocerebellar ataxias (SCAs) 1,2,3 and 6 using distance weighted discrimination (DWD) on 7T MRS from 3 brain regions of 68 SCA patients. Each subject contributed to the DWD model a 50-dimensional vector of concentrations. SCA6 was classified from SCAs 1-3 with high reliability (90%) and SCA2 was classified from SCA3 with moderate success (84%), while SCA1 could not reliably be classified from SCA2 (62%) or SCA3 (48%) with the current model.

Abnormal Thalamic Metabolism in End-Stage Renal Disease Patients with Restless Legs Syndrome

Xueying Ma¹, Dun Ding¹, Peng Li², Fengli Liang¹, Zhuonan Wang¹, Yingxiang Sun¹, Haining Li¹, and Ming Zhang¹

¹Medical Imaging, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, People's Republic of China, ²Imaging Department, NO.215 Hospital of Shaanxi Nuclear Industry, Xianyang, People's Republic of China

Restless legs syndrome (RLS) was very common among ESRD patients. However, the pathophysiologic mechanisms of RLS in ESRD patients were largely unclear. Here we analyzed the thalamic metabolites using ¹H MRS and the correlation between sleep/RLS score and metabolites, compared with corresponding normal controls. The results showed that the Cho/Cr ratio increased and NAA/Cr ratio decreased in thalamus of ESRD patients. The correlation between Cho/Cr ratio and RLS score was significant. It indicated that the sleep disturbance in ESRD patients with RLS might be associated with the abnormal thalamocortical activation of human sleep regulation system.

4642 Computer 10 The influence of mild hypercapnia on brain intracellular pH, phosphate metabolites and cerebral blood flow a multinuclear (¹H/³¹P) MR study at 7T.

Devashish Das¹, Aneurin James Kennerley¹, Samuel Harris¹, and Jason Berwick¹

¹University of Sheffield, Sheffield, United Kingdom

Permissive hypercapnia is commonly used as vasodilatory challenge in clinical applications and basic research. During fMRI experiments continuous exposure to mild (3-10%) CO₂ can be applied to derive stimulus induced changes in the cerebral rate of oxygen consumption (CMRO₂) by measuring cerebral blood flow and blood oxygenation dependent (BOLD) signal. Previous data from anesthetized primate during hypercapnia suggested increase in CBF are accompanied by decreases in neuronal activity. In this context, using multinuclear (³¹P/¹H) and multi-parametric MR we show that mild exposure to hypercapnia elevates regional CBF, and can cause marginal but consistent drop in intracellular pH of rat brain, despite constant [ADP ~25-35μM] and [ATP ~3-2.4mM] to that of resting brain. Our findings support the view that unspecific drop in brain pH may likely elevate regional CBF, thereby sustain oxygen supply-to-demand ratio in rat brain.

¹Auburn University, Auburn, AL, United States, ²MR R&D, Seimens Healthcare, Malvern, PA, United States, ³University of Massachusetts, Worcester, MA, United States

Tay-Sachs Disease (TSD) is a fatal neurodegenerative disorder of children and the sheep model of TSD is a powerful tool to study the disease and evaluate novel therapies. One such therapy, adeno associated viral (AAV) gene therapy has resulted in a 2-fold increase in lifespan and biomarkers are needed for clinical trials. 7T MRI shows white and gray matter alterations and MR spectroscopic abnormalities that worsen with TSD disease progression. At humane endpoint the AAV treated sheep has normalization of gray and white matter intensities, but cortical atrophy and MRS alterations persist. 7T MRI and MRS reflect TSD disease severity.

4645 Computer 13 Dependence of degree of motor impairment on the association between motor performance and sensorimotor GABA level in relapsing remitting multiple sclerosis

Pallab Bhattacharyya¹, Micheal Phillips¹, Lael Stone², and Mark Lowe¹

¹Imaging Institute, Cleveland Clinic, Cleveland, OH, United States, ²Neurological Institute, Cleveland Clinic, Cleveland, OH, United States

Gamma aminobutyric acid (GABA), a major inhibitory neurotransmitter, has been implicated as a metabolic marker of multiple sclerosis (MS). Previously it has been shown that sensorimotor cortex GABA level is higher in relapsing remitting MS (RRMS) patients with poorer motor performance. In this study, the association between cortical GABA level and motor performance, as measured by 9-hole peg test score, has been studied for groups of patients with RRMS with different degrees of motor impairment. The results suggest that cortical GABA has more involvement in motor performance in early stage of RRMS or in less impaired patients.

4646 Computer 14 Baseline of Chemical Exchange Saturation Transfer Imaging for Brain

The purpose of this study is to assess the CEST effect and contrast of various brain regions in normal for phase cycle-CEST MR imaging. Subjects were five healthy volunteers. All slice positions were set on the nucleus basalis level. ROIs were set as thalamus, frontal, occipital, putamen, and gray matter on right and left brain hemispheres of each subject. There was no significant difference in mean MTR_{asym} values among each brain region ($P > 0.01$ for all). CEST effects for normal brain tissue had no dependency on region and/or left-right hemispheres.

Striatal 7T 1H-MRS in two Huntington's Disease Mouse Models (zQ175 and YAC128)

Bretta Russell-Schulz¹, Andrew Yung¹, Austin Hill², Alex L MacKay^{1,3}, Piotr Kozlowski¹, and Blair R Leavitt²

¹Radiology, University of British Columbia, Vancouver, BC, Canada, ²Centre for Molecular Medicine and Therapeutics, University of British Columbia, Vancouver, BC, Canada, ³Physics and Astronomy, University of British Columbia, Vancouver, BC, Canada

Two Huntington's disease (HD) mouse models with difference rates of disease progression, zQ175 and YAC128, were examined using 7T proton magnetic resonance spectroscopy of mice aged 6-7 months. zQ175 heterozygous and homozygous genotypes showed significantly decreased [NAA] and increased [mI] compared to wild type. No differences in metabolite concentrations were found between YAC128- (wild type) and YAC128+ mice. A slow HD disease course in YAC128+ genotype may be the reason for lack of measured metabolite concentration differences.

QSM meets MRS: The influence of subcortical iron on glutamatergic neurotransmission in a movement disorder population

Ahmad Seif Kanaan^{1,2}, Alfred Anwander¹, Andreas Schäfer³, Berkin Bilgic⁴, Torsten Schlumm¹, Jamie Near⁵, Kirsten Müller-Vahl², and Harald E. Möller¹

¹Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ²Department of Psychiatry, Social Psychiatry and Psychotherapy, Hannover Medical School, Hannover, Germany, ³Diagnostic Imaging, Magnetic Resonance, Research & Development, Siemens Healthcare GmbH, Erlangen, Germany, ⁴Martinos Center for Biomedical Imaging, Charlestown, MA, United States, ⁵Douglas Mental Health University Institute and Department of Psychiatry, McGill University, Montreal, QC, Canada

We use a combination of Quantitative Susceptibility Mapping and 1H-MRS to examine the role of iron and its association with glutamatergic signalling in Gilles de la Tourette syndrome (GTS). GTS is a neurodevelopmental movement disorder with abnormalities in the neurotransmission of dopamine and GABA and, as shown more recently, also in subcortical glutamate (Glu) and glutamine (Gln). In this work, we observed that GTS patients exhibit reductions in cerebral iron levels and report a general association between iron and the Gln:Glu ratio. This work provides a good example of utilizing multi-modal neuroimaging methods to interrogate pathophysiology at multiple scales.

Effects of astrocytic Nrf2 activation on recently-identified ¹³C and ¹H MRS flux-based biomarkers of mitochondrial energetics and neurotransmitter cycling in Huntington's Disease

Golam M. I. Chowdhury¹, Peter Dixon², Robin de Graaf³, Xiaoxian Ma⁴, Johnson A Johnson⁵, Jeffrey A Johnson⁵, Larry Park⁶, Gerard Sanacora¹, Douglas L Rothman⁴, and Kevin L Behar¹

¹Department of Psychiatry, Yale University School of Medicine, New Haven, CT, United States, ²Department of Psychiatry, Yale University School of Medicine, ³Department of Radiology and Biomedical Imaging, Yale University School of Medicine, New Haven, United States, ⁴Department of Radiology and Biomedical Imaging, Yale University School of Medicine, New Haven, CT, United States, ⁵School of Pharmacy, School of Pharmacy, University of Wisconsin, Madison, WI, United States, ⁶CHDI Management, CHDI Management/CHDI Foundation, Los Angeles, United States

Alterations in brain glucose and energy metabolism is observed in Huntington's Disease (HD) and HD animal models. 1H-[¹³C]-MRS can be readily adapted to measure metabolic pathway flux by use of ¹³C-labeled substrates. In this study we assessed whether activation of the astroglial Nrf2-ARE pathway in the R6/2 mouse model of HD, which has shown therapeutic potential in HD animal models, can reverse the reduction in ¹³C labeling seen previously in R6/2 mice. In cortex and striatum, astroglial Nrf2 activation led to increased amino acid ¹³C labeling, suggesting a degree of improvement in mitochondrial and neurotransmitter fluxes in the R6/2 mice.

Longitudinal Changes of Metabolites Measured by Proton Magnetic Resonance Spectroscopy and Their Correlations with Behavioral Outcomes in a Rat Model of Kainic Acid Induced Spinal Cord Injury

Mingming Zhu¹, Alice Shum-Siu², Emily Martin², Abby Wade², Darlene Burke², David S Magnuson², and Chin K Ng¹

¹Diagnostic Radiology, University of Louisville School of Medicine, Louisville, KY, United States, ²Neurological Surgery, University of Louisville School of Medicine, Louisville, KY, United States

We measured the profile of major metabolites longitudinally using MRS in spinal cord gray matter of kainic acid (KA) injured rats at both 7 and 14 days post KA administration and correlated their concentrations with functional outcomes assessed by the Basso, Bresnahan, and Beattie (BBB) Open Field Locomotor scores. Our preliminary findings indicate that metabolite concentrations in the lower lumbar spinal cord gray matter, caudal to the injury epicenter, as detected by in vivo 1H-MRS, could be used as injury and recovery biomarkers in SCI animal models.

In this study, we applied dynamic nuclear polarization (DNP) technique to investigate C1 labeled ¹³C pyruvate to lactate conversion on hypoxic ischemia (HI) injured neonatal mouse brains during development. Our results showed that lower pyruvate level and higher lactate to pyruvate ratio on the injured hemisphere in comparison to the non-injured hemisphere at the day of injury (P10). This difference narrows as the brain matures. With this technique, we are able to examine individuals' response to HI in vivo during brain development.

4653

Implications of Obstructive Sleep Apnea on Global Cerebral Metabolic Rate of Oxygen

Ana E Rodriguez-Soto¹, Yulin Chang¹, Wen Cao¹, Zachary B Rodgers¹, John A Detre², Erin K Englund¹, Sarah Leinwand³, Richard Schwab³, Michael C Langham¹, and Felix W Wehrli¹

¹Department of Radiology, University of Pennsylvania, Philadelphia, PA, United States, ²Department of Neurology, University of Pennsylvania School of Medicine, Philadelphia, PA, United States, ³Division of Sleep Medicine, Department of Medicine, University of Pennsylvania, Philadelphia, PA, United States

Obstructive sleep apnea (OSA) is a chronic disorder caused by intermittent obstruction of the upper airways during sleep. Neurocognitive deficits in this population have previously been associated with altered brain metabolism. In fact, a recent pilot study suggests that global cerebral metabolic rate of oxygen (CMRO₂) may be a potential marker of oxygen metabolic dysfunction in this population. Here, we present preliminary results from an ongoing study designed to quantify CMRO₂ in subjects with OSA and matched controls. Initial results suggest that apneics have overall lower baseline CMRO₂ and increased response to volitional apnea, a paradigm to mimic spontaneous apneas.

Mutant huntingtin dosage effect on incidence of high striatal Glutamine in a mouse model of Huntington's disease – a symptom of liver pathophysiology?

Thomas Mueggler¹, Andreas Bruns¹, Laurence Ozmen¹, Herve Schaffhauser¹, Basil Künnecke¹, and Markus von Kienlin¹

¹Roche Pharma Research and Early Development, Hoffmann-La Roche Pharmaceuticals Ltd, Basel, Switzerland

In contrast to transgenic models of Huntington's disease (HD) newly available knock-in models, such as the HttQ175, recapitulate the heterozygosity present in the clinically observed pathophysiology. Here we report a longitudinal assessment of striatal metabolites using 1H-MRS and volumetry in 30+ brain regions in both male and female HttQ175 mice. Apart from a genotype-specific, progressive neurodegenerative phenotype present in both genders, we discovered an entirely novel feature in mouse models of HD, namely individuals with abnormally high glutamine (Gln) levels, whose incidence increased with mutant Htt gene dosage. In line with emerging data on a widespread peripheral metabolic perturbation in HD, we hypothesize that this excessive Gln is a consequence of disordered hepatic metabolism.

Morgan Department of Radiology and Radiological Science, Johns Hopkins university, Baltimore, MD, United States, ³MRI, Shandong Medical Imaging Research Institute, ⁴Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins university, Baltimore, MD, ⁵Shandong University, ⁶MRI, Philips Healthcare, Shanghai, People's Republic of China

This study was aimed to evaluate the differences between PD motor subtypes of GABA+ levels using MEGA-PRESS. PD patients were classified into PIGD and TD groups; sixteen healthy controls were recruited. All subjects underwent 3T MR examination including MEGA-PRESS. We found that GABA+ concentration was lower in PD compared with controls; furthermore, the TD group was lower than PIGD. In PD patients, the GABA+ levels were correlated with UPDRS scores. The results suggest that GABAergic dysfunction may play an important role in the pathogenesis of Parkinson's disease. MEGA-PRESS provides a valuable examination method to discriminate between PD motor subtypes.

[Investigating the use of arterial spin labeling perfusion as a substitute to DCE-MRI in primary tumor perfusion of nasopharyngeal carcinoma](#)

Meng Lin¹, Xiaoduo Yu¹, Bing Wu², Dehong Luo¹, Han Ouyang¹, and Chunwu Zhou¹

¹Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, People's Republic of China, ²GE Healthcare MR research China, Beijing

Assessment of perfusion is important in tumor diagnosis, stage and therapeutic effect evaluation. This study aimed to investigate the relationship between arterial spin labeling (ASL) (with PLD=1.0, 1.5 and 2.0s) and DCE-MRI parameters of nasopharyngeal carcinoma (NPC). Two observers measured the tumor blood flow (TBF) by ASL and DCE derived parameters including MaxSlop, CER, IAUGC, Ktrans, Kep and Ve. TBF showed moderate to strong correlations between all three TBF and DCE-MRI parameters except between all TBF with Ve and between TBF of PLD1.5s and CER. ASL is a feasible non-invasive tool in NPC to quantitatively assess the perfusion.

[Detectability and anatomical location identification of cholesteatoma with thin-slice non-echo planar imaging diffusion-weighted image \(nEPID\) using fused nEPID and CT\(nEPID-CT\)](#)

Toshitada Hiraka¹, Masafumi Kanoto¹, Yuuki Toyoguti¹, Yoshihiro Konno¹, Yasuhiro Sugai¹, and Takaaki Hosoya¹

¹Diagnostic Radiology, Yamagata University Faculty of Medicine, Yamagata, Japan

Non-echo planar imaging diffusion-weighted imaging (nEPID) is a useful tool for diagnosing middle ear cholesteatoma. The cut-off value of nEPID has not yet been determined, however, as fused thin-slice nEPID and computed tomography (nEPID-CT) color imaging cannot correctly distinguish cholesteatoma from other soft tissue. We examined the detectability of cholesteatoma with nEPID using nEPID-CT color images obtained as preoperative studies. The appropriate cut-off value of the signal intensity ratio on nEPID is 0.925 on the receiver operating characteristic (ROC) curve with Youden's index. Here, we evaluate the efficacy of nEPID-CT color images based on this nEPID cut-off value.

[B0 and B1 Field Inhomogeneity Consideration in Pseudo-continuous ASL Due to the Presence of Carotid Artery Stenting](#)

Chien-Yuan Eddy Lin^{1,2}, Jianxun Qu², Ai-Chi Chen¹, Yen-Chien Wu³, David Yen-Ting Chen³, Ying-Chi Tseng³, and Chi-Jen Chen³

¹GE Healthcare, Taipei, Taiwan, ²GE Healthcare MR Research China, Beijing, People's Republic of China, ³Department of Radiology, Taipei Medical University - Shuang Ho Hospital, New Taipei City, Taiwan

Pseudo-continuous arterial spin labeling (pCASL) has been recently used for investigating cerebral hemodynamic change on the patient receiving carotid artery stenting (CAS) because it permits repeated measurement of absolute cerebral blood flow in a short interval without MR contrast agent or radioactive material. However, labeling efficiency of pCASL has been proved to be dependent on B₀ and B₁ inhomogeneity. The aim of this study was to understand how inhomogeneous of the B₀ and B₁ at labeling position of pCASL and find the remedies of the pCASL measurement for the CAS patient.

The application of enhanced MRI with 3D-STIR-SPACE for Brachial Plexus lesions

Lan Zhang¹ and Wen Chang Chen²

¹MRI, The 1st affiliated hospital of Henan university of TCM, Zhengzhou, People's Republic of China, ²Chang Gung Memorial Hospital, Chiayi Branch, Taiwan

Imaging the brachial plexus is a challenge due to its complicated structure. The purpose of this study is to improve the diagnosis ability for brachial plexus 3D-STIR-SPACE technique with contrast agent administration. After contrast agent administration, signals of adjacent vessels were suppressed due to reduction in its T1 relaxation time which became similar to that of fat. The outlines of nerves would be clearer with respect to surrounding tissues. The image of 3D-STIR-SPACE technique with contrast agent was superior to that without contrast agent. It might be a better way to evaluate anatomies and pathologies of the brachial plexus.

Positional variation of parotid glands in the treatment position of head and neck radiotherapy with immobilization: a pilot study on healthy volunteers using high spatial resolution 3D MRI at 1.5T

Jing Yuan¹, Yihang Zhou¹, Oilei Wong¹, Winky Wing Ki Fong², George Chiu², Kin Yin Cheung¹, and Siu Ki Yu¹

¹Medical physics and research department, Hong Kong Sanatorium & Hospital, Happy Valley, Hong Kong, ²Department of Radiotherapy, Hong Kong Sanatorium & Hospital, Happy Valley, Hong Kong

Investigation of positional and geometric variations of organ-at-risk (OAR) in head-and-neck (HN) radiotherapy (RT) is greatly limited by the poor soft tissue contrast of X-ray-based imaging. We investigated the positional variation of parotid glands (PG) in the immobilized HN-RT treatment position on healthy volunteers using high-spatial-resolution 3D-MRI at 1.5T. The results showed that PGs generally had sub-millimeter and sub-degree group mean error, systematic error and random error under immobilization. Although PGs generally showed insignificant positional variations from global HN, individual left and right PG might move independently and resulted in insignificant positional correlations with each other and global HN.

Measurement of blood flow in normal parotid glands using pseudo-continuous arterial spin labeling: comparison between 2D echo-planar and 3D turbo spin-echo sequences.

Katsuhiko Inoue¹, Maki Umino², Ryohei Nakayama³, Shinichi Takase¹, Tsunehiro Yamahata¹, Makoto Obara⁴, Masayuki Maeda⁵, and Hajime Sakuma⁶

¹Department of Radiology, Mie University Hospital, Mie, Japan, ²Department of Radiology, Mie University School of Medicine, Mie, Japan, ³Department of electronic and Computer Engineering, Ritsumeikan University, Shiga, ⁴Philips Electronics Japan, Tokyo, Japan, ⁵Department of Advanced Diagnostic Imaging, Mie University School of Medicine, Mie, Japan, ⁶Department of Radiology, Mie University School of Medicine, Tsu, Mie, Japan

Evaluation of parotid blood flow (PBF) may provide an insight into the pathophysiology of parotid diseases. We evaluated and compared the blood flow of normal parotid glands in six volunteers using 2D-echo-planar (EP) and 3D-turbo-spin-echo (TSE) pseudo-continuous ASL (pCASL) sequences. Visual assessment indicated that 3D-TSE pCASL maps were significantly better for delineating normal parotid glands. 3D-TSE pCASL showed larger PBF values than 2D-EP pCASL. Fewer measurement errors were observed in 3D-TSE pCASL data. We concluded that 3D-TSE pCASL is more suitable for the evaluation of PBF than 2D-EP pCASL.

The parotid gland function is evaluated by gustatory stimulation using scintigraphy in clinic. It is supposed to measure the water component of parotid gland using PD MRI instead of scintigraphy. In this study, we initially developed the evaluation of parotid gland function by PD MRI, and 10 healthy volunteers underwent double echo EPI with gustatory stimulation. Maximal drop ratio (MDR), time to peak (TTP), drop slope (DS), recovery slope (RS) and recovery ratio (RR) were calculated. The signal intensity dropped significantly after gustatory stimulation on PD image ($P < 0.01$). MRI allows quantification of parotid gland function using semi-quantitative functional parameters.

3D pituitary dynamic MR imaging using the TWIST and Iterative reconstruction TWIST

Yusuke Yokota¹, Yasutaka Fushimi¹, Tomohisa Okada², Akira Yamamoto¹, Tsutomu Okada¹, Aurelien Stalder³, Christoph Forman³, Michaela Schmidt³, and Kaori Togashi¹

¹Department of Diagnostic Imaging and Nuclear Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan, ²Human Brain Research Center, Graduate School of Medicine, Kyoto University, Kyoto, Japan, ³Siemens Healthcare GmbH, Erlangen, Germany

The aim of this study is to perform a comparison between 3D pituitary dynamic study using time-resolved angiography with interleaved stochastic trajectories (TWIST) and TWIST with iterative reconstruction (IT-TWIST). IT-TWIST was retrospectively reconstructed from the raw data of TWIST by using L1 wavelet regularization in space and time. One neuroradiologist put regions of interest in pituitary stalk and anterior lobe and made time intensity curve. The slope of enhancement in the early phase was evaluated. In addition, image quality was visually evaluated. IT-TWIST yielded higher slope of enhancement in the early phase in anterior lobe and better image quality.

Correlation of human papilloma virus status with quantitative perfusion/diffusion MRI parameters and metabolic 18F-FDG-PET parameters in oral cavity and oropharyngeal squamous cell carcinoma: Comparison between primary tumor lesions and metastatic lymph nodes

Miran HAN¹, Jin Wook Choi¹, and Su Jin Lee²

¹Radiology, Ajou University Medical Center, Suwon, Korea, Republic of, ²Nuclear medicine, Ajou University Medical Center, Suwon, Korea, Republic of

We evaluated association between perfusion/diffusion MRI parameters, metabolic ¹⁸F-FDG PET parameters and HPV status in not only primary oral cavity-oropharyngeal squamous cell carcinoma but also its metastatic lymph nodes. Any significant difference was not found in quantitative perfusion, diffusion, metabolic parameters of primary tumor between HPV-positive and HPV-negative groups. In case of metastatic lymph node, only metabolic parameters were significantly higher in HPV-positive group. In our study population, HPV status of primary OC-OPSCC and metastatic lymph nodes did not translate into different perfusion/diffusion parameters. Larger study population is needed to establish whether imaging parameters can represent the HPV status.

Reduced FOV with Multi-shot IRIS Provides Improved Diffusion Tensor Imaging in the Cervical Spinal Cord

Samantha By^{1,2}, Ed Mojahed^{2,3}, Saikat Sengupta², and Seth A. Smith^{1,2,4}

¹Biomedical Engineering, Vanderbilt University, Nashville, TN, United States, ²Vanderbilt University Institute of Imaging Science, Vanderbilt University Medical Center, Nashville, TN, United States, ³Philips Healthcare, Nashville, TN, United States, ⁴Radiology and Radiological Sciences, Vanderbilt University Medical Center, Nashville, TN, United States

Spinal cord DTI is technically challenging, primarily due to the small size of the cord and physiological motion. We compare three different sequences to address these challenges: 1) single-shot EPI (ss-EPI), 2) multi-shot EPI with 2D navigation (IRIS), and 3) multi-shot EPI with reduced FOV (IRIS+iZOOM). Results indicate that IRIS alleviates geometric distortion present in ss-EPI. The combination of IRIS and iZOOM, however, provides the most consistent and least distorted diffusion-weighted images. These effects are clearly seen in the fractional anisotropy, axial diffusivity, and radial diffusivity maps, where exceptional contrast between gray and white matter are observed with IRIS+iZOOM.

¹Department of Radiological Technology, Hokkaido University Hospital, Sapporo, Japan, ²Division of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, Japan, ³Hitachi, Ltd., Healthcare Company, ⁴Hitachi, Ltd., Research and Development Group
- To evaluate the homogeneity of B1+ and signal intensity of the thoracolumbar spine with different arm positions. Twenty volunteers were scanned with 4-channel RF transmit coil at 3T. Three arm positions were used; arms on the bed, arm lift, and arm up position. Axial B1+ maps and sagittal T1WI were obtained individually with each arm position. Mean and SD values of FA, and CNR with arm lift and arm up position were significantly superior with arms on the bed position. Inhomogeneities of B1+ and signal intensities were improved by simply changing the arm position at 3T thoracolumbar spine imaging.

 Gergely David¹, Eveline Huber¹, Nikolaus Weiskopf^{2,3}, Siawoosh Mohammadi^{3,4}, and Patrick Freund^{1,2,3}
¹Spinal Cord Injury Center, Balgrist University Hospital, Zurich, Zurich, Switzerland, ²Department of Neurophysics, Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ³Wellcome Trust Centre for Neuroimaging, UCL Institute of Neurology, London, United Kingdom, ⁴Department of Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Neuroimaging of the cervical cord has demonstrated above-level neurodegeneration after traumatic spinal cord injury. In this study, we investigated below-level neurodegeneration with optimized high-resolution MRI sequences, including diffusion tensor imaging and structural imaging, applied to the lumbar cord in patients with cervical injury. Our results demonstrate that atrophy and axonal degeneration are prominent in the lumbar cord reflected by structural and diffusivity changes. Furthermore, the extent of these changes is related to clinical impairment. This study shows neurodegeneration below the level of injury and demonstrates the clinical feasibility of acquiring readouts of tissue-specific changes in the lumbar cord.

Computer 46

Voxel-based analysis of grey and white matter degeneration above the level of injury in cervical spinal cord injury

Eveline Huber¹, Gergely David¹, Niklaus Weiskopf^{2,3}, Siawoosh Mohammadi^{3,4}, and Patrick Freund^{1,2,3,5}

¹University Hospital Balgrist, University of Zurich, Zurich, Switzerland, ²Department of Neurophysics, Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ³Wellcome Trust Centre for Neuroimaging, UCL Institute of Neurology, University College London, London, United Kingdom, ⁴of Systems Neuroscience, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ⁵Department of Brain Repair and Rehabilitation, UCL Institute of Neurology, University College London, London, United Kingdom

We studied the extent of cervical grey and white matter neurodegeneration above the level of injury after traumatic spinal cord injury (SCI) using high-resolution structural and diffusion MRI data. We found marked atrophy of both white and grey matter alongside diffusivity changes associated with axonal degeneration within the major spinal tracts. The extent of structural decline related to clinical impairment. These tract specific changes and clinicopathological relationships shed light into underlying neurodegenerative disease mechanisms, and therefore these measurable changes hold potential to serve as neuroimaging biomarkers of cord pathology.

The Utility of DTI and NODDI for Assessment of Disease Severity and in Predicting Postoperative Neuronal Recovery: An Atlas-based Tract Specific Study

Tomohiro Takamura¹, Ryo Ueda², Masaaki Hori¹, Ryusuke Irie¹, Koji Kamagata¹, Michimasa Suzuki¹, and Shigeki Aoki¹

¹Juntendo University, Tokyo, Japan, ²Tokyo Metropolitan University

Quantification of disease severity and prediction of postoperative outcome were essential in management of cervical spondylotic myelopathy (CSM). The purpose of this study was to investigate correlation between diffusion metrics, including DTI or NODDI in spinal cord pathways, and the severity of CSM, as well as their predictive ability for postoperative recovery. We elucidated that the disease severity was significantly correlated with FA and ODI, and postoperative recovery correlated with RD and MD. The lateral funiculi and lateral corticospinal tract seemed to be the predominant spinal cord pathway that correlated with disease severity and postoperative recovery.

Computer 48

Microstructural assessment of the cervical spinal cord using high-resolution, 1 dimensional MRI

Rexford Newbould¹ and Paul M Matthews²

¹Imanova, London, United Kingdom, ²Division of Brain Sciences, Imperial College London, London, United Kingdom

A 1-dimensional MR sequence termed Fine Structural Analysis (fineSA) was applied to the human cervical spinal cord in order to determine if spinal tracts and nerve fibres of the dorsal horn could be identified from the spectral regularity of their myeloarchitecture. Repeatable 60 μ m peaks could be attributed to the dorsal horn as opposed to projective nerve tracts of the cord. This analysis might be able to identify the loss of neurons via changes in packing density that would be proximal to macrostructural atrophy detectable on more classical MR sequences.

(free)Surfing ANTs: a comparative study

Santi Puch¹, Paulo Rodrigues¹, David Moreno-Dominguez¹, Marc Ramos¹, and Vesna Prčkowska¹

¹Mint Labs, Barcelona, Spain

Robust and automated tools such as *FreeSurfer* or *ANTs* for brain segmentation and quantification have been of utmost importance in the recent advancements in the Neuroimaging field. However, the reproducibility and variability of their results are often uncertain. In this study, we analyzed their reproducibility and compared their outputs for different brain structures. We observe that both tools give high reproducibility for volumetric studies and give similar results in most of the examined cases. However, in some structures (pallidum, rostral-anterior cingulate) there are more pronounced and significant differences. Our results also indicate slightly better reproducibility of *ANTs* over *FreeSurfer*.

Dura Mater imaging with UTE T_2^* Mapping

Yuki Kanazawa¹, Masafumi Harada¹, Mitsuharu Miyoshi², Yuki Matsumoto³, Hiroaki Hayashi¹, Toshiaki Sasaki⁴, Natsuki Ikemitsu⁴, and Michael Carl²

¹Graduate School of Biomedical Sciences, Tokushima University, Tokushima, Japan, ²Global MR Applications and Workflow, GE Healthcare, ³Graduate school of Health Science, Tokushima University, ⁴School of Health Sciences, Tokushima University

To assess signal of dura mater acquired from UTE imaging, we evaluated this component with T_2^* mapping derived from a multi-echo UTE sequence of healthy volunteers. We then compared measured T_2^* values of cranium and dura mater. The mean T_2^* value of dura mater in five healthy volunteers was significantly higher than that of cranium ($P < .05$). It is found that the T_2^* decay of dura mater was faster than the cranium components. UTE T_2^* mapping makes it possible to obtain detailed information for meningeal abnormalities.

Reproducibility of human habenula characterization with high-resolution quantitative susceptibility mapping at 3T

Seung-Kyun Lee^{1,2}, Seulki Yoo^{1,2}, and Anup S Bidesi^{1,2}

¹Department of Biomedical Engineering, Sungkyunkwan University, Suwon, Korea, Republic of, ²Center for Neuroscience Imaging Research, Institute for Basic Science, Suwon, Korea, Republic of

We investigated scan-rescan reproducibility of human habenula susceptibility measurement using quantitative susceptibility mapping (QSM) at a 0.5x0.5x0.8 mm³ resolution. Although previously reported paramagnetic enhancement in the habenula (Schenck et al., ISMRM 2015) was confirmed, the paramagnetic center was highly localized within the habenula mass to make the susceptibility quantification vulnerable to partial volume effects. This appeared to limit the reproducibility of peak susceptibility measurements in the habenula to 10-40%, with significant variation among subjects. High resolution scans and reliable coil combination of phase data would be needed to make QSM a more reliable tool for human habenula characterization.

Characterization Of Registration Errors To Screen Aberrant Subject Results Prior To Voxel-Wise Whole Brain Analysis

Roman Fleysher^{1,2}, Namhee Kim^{1,2}, Asif Suri^{1,2}, Michael L Lipton^{1,2}, and Craig A Branch^{1,2}

¹Gross Magnetic Resonance Research Center, Albert Einstein College of Medicine, Bronx, NY, United States, ²Radiology, Albert Einstein College of Medicine, Bronx, NY, United States

Voxel-wise analyses of DTI, fMRI or any other MRI-derived metric, be it for comparing groups or one patient to a control group, require quality registration of images to a template. One or several poorly registered images may skew the distributions of the metric in several voxels leading to incorrect inferences. We propose an approach to screen poorly registered images prior to voxel-wise analysis by comparing subject-wise mean displacements of anatomical landmarks between morphed images and the template estimated using FreeSurfer. We apply this proposed algorithm to demonstrate morph accuracy characterization using two age extreme (18 and 86 year old) templates.

Computer 53

Automatic Segmentation of Human Brain MRI using Sliding Window and Random Forests

Ahmed Serag¹, Emma J Telford¹, Scott Semple¹, and James P Boardman¹

¹University of Edinburgh, Edinburgh, United Kingdom

Volumetric analysis of brain MRI acquired across the life course may be useful for investigating long-term effects of risk and resilience factors for brain development and healthy ageing, and for understanding early life determinants of adult brain structure. We developed an automatic segmentation method for human brain MRI, where a sliding window approach and a multi-class random forest classifier were applied to high-dimensional feature vectors for accurate segmentation. The method performed well on brain MRI data acquired from 179 individuals, analysed in three age groups: newborns (38-42 weeks gestational age), children and adolescents (4-17 years) and adults (35-71 years).

Post-mortem and In Vivo Thalamic Nuclei Identification at 7T with Comparison to Histology

Mobeen Ali¹, Ian Scott², Alain Pitiot³, Karen Mullinger^{1,4}, Andy Bagshaw⁴, Penny Gowland¹, and Richard Bowtell¹

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom, ²Department of Cellular Pathology, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom, ³School of Psychology, University of Nottingham, Nottingham, United Kingdom, ⁴Centre for Human Brain Health (CHBH), University of Birmingham, Birmingham, United Kingdom

The thalamus plays a major role in regulating the transfer of information through the brain and is also implicated in many neurodegenerative diseases. It is therefore crucial to improve our understanding of this key brain structure. Structural differentiation of thalamic nuclei in post-mortem 7T MRI was investigated. Thalamic sub-regions were identified in magnitude, R2*, R1 and magnetisation transfer ratio maps from six post-mortem brains. Edge detection, k-means clustering algorithms and thin-plate spline warping to the Morel atlas were used to systematically identify thalamic nuclei. These data showed good correlation with stained histological sections and in vivo MRI data.

Strategies for Building a Morphologically Faithful Average Brain Template from Population Diffusion MRI Data

Mustafa Okan Irfanoglu^{1,2,3}, Neda Sadeghi², Amritha Nayak^{1,2,3}, and Carlo Pierpaoli^{1,2}

¹Quantitative Medical Imaging Section, NIBIB/NIH, Bethesda, MD, United States, ²SQUITS/NICHD/NIH, Bethesda, MD, United States, ³Henry Jackson Foundation, Bethesda, MD, United States

The availability of anatomically accurate MRI atlases, which can be used as target templates for registration, is essential for quantitative analysis of MRI data. Ideally the computed atlas should be representative of the average features of the population at each voxel location. In this work, we investigate the ability of the most common atlasing approach (i.e. iterative registration followed by averaging) of assuring morphological accuracy. We also evaluate whether constraining the individual deformation fields with deformation-based information helps achieving this goal. We perform our atlas creation tests from full DTI data, using a novel diffusion tensor based diffeomorphic registration technique. We conclude that current atlasing techniques lead to templates that do not faithfully represent the average morphology of the population but that by applying appropriate constraints significant improvements toward this goal can be achieved.

IIT Human Brain Atlas: Enhancement of T1-weighted Template, Tissue Probability Maps and Gray Matter Atlas

Xiaoxiao Qi¹, Shengwei Zhang¹, and Konstantinos Arfanakis¹¹Department of Biomedical Engineering, Illinois Institute of Technology, Chicago, IL, United States

The IIT Human Brain Atlas contains anatomical, DTI, HARDI templates, probabilistic gray matter (GM) labels, probabilistic connectivity-based white matter labels, and major fiber-bundles of the young adult brain. During development of the atlas, spatial normalization was accomplished based on diffusion data. Consequently, matching of the anatomical information of T1-weighted images was not maximized, blurring the T1-weighted template and tissue probability maps, increasing the noise of the T1-weighted template, and lowering confidence of GM labeling and GM label precision. The present work enhanced the quality of the T1-weighted template, tissue probability maps, and GM labels of the IIT Human Brain Atlas.

Computer 57

Multi-modal characterization of white matter for studying language and hand motor function

Yuichi Suzuki¹, Kouhei Kamiya¹, Minoru Mitsuda¹, Akira Kunimatsu¹, Masaaki Hori², Harushi Mori¹, Katusya Maruyama³, Kenji Ino¹, Yasushi Watanabe¹, Jiro Sato¹, Shigeki Aoki², Keiichi Yano¹, and Osamu Abe¹¹Department of Radiology, The University of Tokyo Hospital, Tokyo, Japan, ²Radiology, Juntendo University School of Medicine, Tokyo, Japan, ³Siemens Japan K.K., Tokyo, Japan

We present a preliminary experience of a fiber g-ratio technique using a combination (MT_{sat} and NODDI) in multi-modal characterization of the white matter bundles relevant to language and hand motor function. Tract-specific analyses of the pyramidal tract, accurate fasciculus, and frontal aslant tract were performed using the tractography as volume of interest. The fiber g-ratio, MVF, AVF, and FA were measured, and differences between the hemispheres and among the bundles were tested. This study suggested we can be more sensitive to the lateralities of these bundles by combining myelin imaging and diffusion.

Measuring Transcortical Vasculature with Ultra-high Field (7T) MRI

Allen Timothy Newton¹, Isabel Gauthier², and Rankin W McGugin²¹Radiology and Radiological Sciences, Vanderbilt University Medical Center, Nashville, TN, United States, ²Psychology, Vanderbilt University, Nashville, TN, United States

Direct visualization of intracortical vascular structure holds promise for detection of pathologic conditions currently invisible with conventional clinical MRI. However, imaging of these structures with MRI has been rare, and no validation of the technique has been performed. Here, we use 7T SWI to directly image intracortical vasculature on the microscopic scale with the goal of understanding the within and between subject variance. We found intracortical vascular measurements were reproducible within subjects and were sensitive to between subject variability, indicating that the measurements may be useful as a biomarker of disease processes affecting vasculature within the cortex.

Computer 60

MRI to monitor the impact of positional changes in the airway of sleep apnea patients – A Phase I methodology demonstration at 3T

Huyen Thanh Nguyen¹, Ulysses Magalang², Amir Abdullillah¹, Saba Elias¹, Petra Schmalbrock¹, Preethi Subramanian¹, Shivangi Vora¹, Wenbo Wei¹, Samantha Rojas², Kirsten Emmons³, David Ribble³, and Michael V Knopp¹¹Wright Center of Innovation in Biomedical Imaging, Department of Radiology, The Ohio State University, Columbus, OH, United States, ²Division of Pulmonary, Allergy, Critical Care, and Sleep Medicine, The Ohio State University, Columbus, OH, United States, ³Hill-Rom

We aimed to develop a non-invasive quantitative MRI methodology to assess positional and rotational impact on the airway opening in subjects with history of sleep apnea for a proposed clinical trial. An equipment and software analysis approach was implemented to perform a feasibility demonstration using 9 volunteers. All data analysis was performed on IntelliSpace Portal (ISP) (Philips Healthcare) to validate the angles and perform the assessment of the airway opening in the RP and RG regions. We have established a prototype table setup that enables us to image 7 positions of various head and chest support angles to investigate the best positional changes to improve the airway opening of sleep apnea subjects. The results showed that the actual angles were within 0.10-0.30 from the targeted angles. In conclusion, the developed 3T MRI methodology appears robust to assess the impact of head and chest positional changes on the airway in sleep apnea patients.

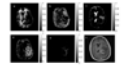

4693

Computer 61

Inter-individual variability in rapid eye movement sleep is associated with brain white matter structure

Shuqin Zhou¹, Qihong Zou², Jing Xu², Jiahui Deng³, Zihui Su², Tianyi Qian⁴, Thomas Beck⁵, Changwei Wu⁶, Hongqiang Sun³, and Jia-Hong Gao²¹Department of Biomedical Engineering, Peking University, Beijing, People's Republic of China, ²Center for MRI Research and Beijing City Key Lab for Medical Physics and Engineering, Peking University, Beijing, People's Republic of China, ³Sixth Hospital, Peking University, Beijing, People's Republic of China, ⁴MR Collaborations NE Asia, Siemens Healthcare, Beijing, People's Republic of China, ⁵Application Development, Siemens Healthcare, Erlangen, Germany, ⁶Graduate Institute of Humanities in Medicine, Taipei Medical University, Taipei, Taiwan

Previous animal studies indicated that sleep is important for cell membrane and myelin maintenance in the brain. Research further suggests that variability in sleep structure may be associated with brain white matter microstructure. In this study, we investigate the relationship between sleep structure parameters evaluated with polysomnography and brain white matter characteristics, as measured by MR diffusion tensor imaging. We find that inter-subject variability of regional white matter characteristics may explain the differences in sleep structure across participants.

-
- 4694 **Computer 62**  Relationship between cortical Grey Matter quantitative Magnetization Transfer and corresponding sub-cortical White Matter in healthy adults
Olivier E. Mougín¹, Prejaas K. Tewarie¹, Benjamin A.E. Hunt¹, Nicolas Geades¹, Peter G. Morris¹, Matthew J. Brookes¹, and Penny A. Gowland¹
¹Sir Peter Mansfield Imaging Centre, School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom
- The aim of this study is to estimate the correlation between myelination in the cortical ribbon and the underlying subcortical WM fibres in healthy adults, using quantitative Magnetization Transfer to assess myelination. The results shows that GM myeloarchitectonic is reflected in the underlying WM in healthy adults.
-
- 4695 **Computer 63**  Relationship between nicotine dependence and the structural changes in the brain of young and middle-aged male smokers: a voxel-based morphometry study
Peng Peng¹, Min Li¹, Ya-Ru Tian¹, Yang Yu¹, Bin Jing², Qing-Lei Shi³, and Tao Jiang¹
¹Radiology, Beijing Chao-Yang Hospital, Beijing, People's Republic of China, ²School of Biomedical Engineering, Capital Medical University, Beijing, People's Republic of China, ³MR Scientific Marketing, Siemens Healthcare Ltd. Diagnostic Imaging
- This study aimed to research the relationship between the volume changes of brain and smoking extent/nicotine dependence. A voxel-based morphometry study between smokers grouped by smoking amount and dependence level was conducted. This study demonstrated the volume of many brain areas decreased with the increase in smoking extent and an opposite correlation between some brain areas and smoking dependence was observed. This study indicated that dependence had limited ability to predict smoking-related brain structure changes. A comprehensive assessment of the situation should be consulted, when clinicians make treatments options.

- 4696 **Computer 64**  Exploring Subvoxel Structures in Brain Tumors using Magnetic Resonance Fingerprinting
Debra McGivney¹, Anagha Deshmane², Chaitra Badve³, Dan Ma¹, Vikas Gulani^{1,3}, and Mark Griswold^{1,2}
¹Radiology, Case Western Reserve University, Cleveland, OH, United States, ²Biomedical Engineering, Case Western Reserve University, Cleveland, OH, ³Radiology, University Hospitals, Cleveland, OH, United States
- We apply a partial volume analysis to MR fingerprinting brain tumor data. In the analysis, the number and types of tissues that make up a given voxel are not assumed to be known *a priori*, which is particularly important in the case of abnormal tissues, such as tumors or edema. We examine the partial volume results in a patient with a glioblastoma multiforme (GBM) and another with a metastasis to look for patterns in healthy tissues, tumor, and the peritumoral region.
-
- 4697 **Computer 65**  Prenatal exposure to phthalate esters and later brain structure change revealed by generalized q-sampling MRI
Yen-Ning Hsu¹, Jun-Cheng Weng^{1,2}, Jeng-Dau Tasi³, Chao-Yu Shen^{1,2,4}, and Shu-Li Wang⁵
¹Department of Medical Imaging and Radiological Sciences, Chung Shan Medical University, Taichung, Taiwan, ²Department of Medical Imaging, Chung Shan Medical University Hospital, Taichung, Taiwan, ³School of Medicine and Department of Pediatrics, Chung Shan Medical University and Hospital, Taichung, Taiwan, ⁴Institute of Medicine, Chung Shan Medical University, Taichung, Taiwan, ⁵National Institute of Environmental Health Sciences, National Health Research Institutes, Miaoli, Taiwan
- Phthalate esters are a group of chemicals that are widely used everywhere. There is an emerging public health issue that the prevalent use of phthalates may affect children's brain development. Therefore, we tried to use generalized q-sampling imaging (GQI) to identify the neurological structure changes of white matter of children's brain induced by prenatal phthalate exposure. The altered GQI indices in the corpus callosum, corona radiata, superior longitudinal fasciculus (SLF), internal capsule, and superior frontal gyrus were found in the children's brain who were prenatal exposure to phthalate esters.
-
- 4698 **Computer 66**  Measuring white matter structure in solid tumor survivors: a fixel-based versus voxel-based approach
Charlotte Sleurs^{1,2}, Jurgen Lemiere¹, Daan Christiaens³, Thibo Billiet⁴, Marjolein Verly², Ronald Peeters², Stefan Sunaert², Anne Uytendaele¹, and Sabine Deprez²
¹Department of Pediatric Hematology and Oncology, University Hospitals Leuven, Leuven, Belgium, ²Department of Radiology, University Hospitals Leuven, Leuven, Belgium, ³Centre for the Developing Brain, King's College London, ⁴Imaging Biomarker Experts, Icometrix
- Neurotoxicity of multi-agent chemotherapy in survivors of solid non-CNS tumors during childhood, has limitedly been investigated. Nowadays, diffusion-weighted imaging (DWI) is implemented in clinical studies to examine potential white matter changes. However, standard voxel-based analyses of diffusion measures such as fractional anisotropy (FA), only provide information about local white matter structure on a voxel-level, but lack specific information about fiber populations within a voxel. Therefore, we compared a fixel-based versus voxel-based group comparison analysis of DWI images in survivors of pediatric solid tumor versus healthy age-matched controls.
-
- 4699 **Computer 67**  High resolution volumetric 3D-SoS MPRAGE detection of carotid intraplaque hemorrhage
J. Scott McNally¹, Laura Eisenmenger¹, Seong-Eun Kim¹, Rock Hadley¹, Adam De Havenon², Jason Mendes¹, Gerald Treiman³, and Dennis Parker¹

¹Radiology, University of Utah, Salt Lake City, UT, United States, ²Neurology, University of Utah, Salt Lake City, UT, United States, ³Surgery, Salt Lake City VA Medical Center

To provide a better method of detection and quantification of carotid intraplaque hemorrhage (IPH), we developed a motion-robust 3D radial stack of stars (SoS) MPRAGE sequence. 3D SoS MPRAGE outperformed 3D TOF in the detection and quantification of carotid IPH when compared with histology. The sequence was robust to motion and flow related artifacts. This sequence, when combined with high-SNR neck shape specific coils, can help identify stroke etiology, determine future stroke risk, and evaluate treatment response by quantifying IPH volume in future clinical trials aimed at decreasing carotid IPH.

Extraction of Dentatorubrothalamic Fiber Tracts in Human Brain Using Probabilistic Fiber Tracking and Unsupervised Clustering Algorithm
Qing Ji¹, Angela Edward¹, John O. Glass¹, Zoltan Patay¹, and Wilburn E. Reddick¹

¹Diagnostic Imaging, St. Jude Children's Research Hospital, Memphis, TN, United States

We proposed a novel robust method to extract the dentatorubrothalamic tract (DRTT) in the human brain from DTI images. First, the method was tested on healthy control subjects, then on 30 medulloblastoma patients who had undergone resection of their posterior fossa tumors. Patterns of bilateral, left only, right only and even no DRTT were observed. Validation with multiple manual ROIs along the known pathway confirmed the extracted DRTTs. This suggests that the proposed method may provide an object way to access the DRTTs in medulloblastoma patients post-surgery.

Grey matter atrophy measured in-vivo with 9.4T MRI in the experimental autoimmune encephalomyelitis mouse model of multiple sclerosis
A. Max Hamilton^{1,2,3,4}, Nils D. Forkert^{1,2}, Runze Yang^{1,2,3,4}, Ying Wu^{1,2,3,4}, James A. Rogers^{2,3}, V. Wee Yong^{2,3}, and Jeff F. Dunn^{1,2,3,4}

¹Department of Radiology, University of Calgary, Calgary, AB, Canada, ²Hotchkiss Brain Institute, University of Calgary, Calgary, AB, Canada, ³Department of Clinical Neurosciences, University of Calgary, Calgary, AB, Canada, ⁴Experimental Imaging Center, University of Calgary, Calgary, AB, Canada

Grey matter atrophy has become a clinically relevant marker of progressive disability in multiple sclerosis (MS). To better study atrophy in MS, mouse models that have grey matter loss are needed. A possible candidate is the experimental autoimmune encephalomyelitis (EAE) mouse model. We used high-resolution magnetic resonance imaging (MRI) and atlas-based regional volumetrics to measure the volumes of 62 structures in the brains of EAE mice, 66 days post-induction. We identified atrophy in 19 structures including the cortex, cerebellum, striatum, thalamus, hippocampus, and corpus callosum. Using MRI we can study atrophy in this inflammatory model of MS.

Günther Grabner^{1,2}, Thomas Haider³, Alexander Rauscher⁴, Hannes Traxler⁵, Siegfried Trattnig¹, and Simon Daniel Robinson¹

¹High Field Magnetic Resonance Centre, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria, ²Department of Radiologic Technology, Carinthia University of Applied Sciences, Klagenfurt, Austria, ³University Clinic for Trauma Surgery, Medical University Vienna, Austria, ⁴UBC MRI Research Centre, University of British Columbia, Canada, ⁵Center of Anatomy and Cell Biology, University of Vienna, Austria

Image-guided neurosurgery uses information from a wide spectrum of imaging methods which are registered to the patient's skull so that they correspond to the intraoperative macro- and microscopic view at the start of the operation. During neurosurgical intervention the correspondence between imaging and optical systems breaks because of brain shift down. In this study we demonstrate that Susceptibility-Weighted Imaging and automatic vessel segmentation can be used for visualization and segmentation of superficial cortical veins which can be used as additional reference system during operation.

Cortical thickness and morphometric volumes derived from Multi-Echo MPRAGE scans acquired with different head coils

Ross William Mair^{1,2} and Andre J. van der Kouwe²

¹Center for Brain Science, Harvard University, Cambridge, MA, United States, ²Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Charlestown, MA, United States

Variations in modern head-coil design lead to sensitivity differences, changes in intensity profiles, and image SNR. As morphometric analysis is based on automated analysis of image intensity and contrast variations, such variation of head coil may be expected to provide variation in morphometric results. We investigated the morphometric results from MEMPRAGE scans on subjects scanned in pairs of different head coils. We saw very limited variation in basic morphometric results from subjects scanned on the same day in different head coils. Cortical thickness variations are generally less than 50 μm , although some larger values were observed in portions of the temporal lobe. Larger differences were observed in volumes of small sub-cortical structures. These structures often have high variability in repeat measurements. However, intensity and SNR variations between coils are often most felt in the deeper regions of the brain, perhaps contributing to wider variation for these structures.

Is the length of the white matter fiber bundles underlying the thalamo-cortical loop associated with sleep spindles? – a preliminary study

Pierre-Olivier Gaudreault^{1,2}, Julie Carrier^{1,2,3}, Maxime Descoteaux⁴, and Samuel Deslauriers-Gauthier⁴

¹Center for advanced research in sleep medicine, Hôpital du Sacré-Coeur de Montréal, Montreal, QC, Canada, ²Department of Psychology, University of Montreal, Montreal, QC, Canada, ³Research Center, Institut universitaire de gériatrie de Montréal, Montreal, QC, Canada, ⁴Sherbrooke connectivity imaging lab, Computer science Department, University of Sherbrooke, Sherbrooke, QC, Canada

Sleep spindles, an EEG manifestation generated by the thalamo-cortical loop and implicated in sleep-dependent learning were recently associated to voxel-based metrics of brain white matter. Thus, we aimed to investigate if specific bundles of streamlines underlying the thalamo-cortical loop will be associated to sleep spindles variables in twenty-five young subjects. Our study showed that the median fiber length of streamlines connecting the thalamus to the anterior and middle part of the superior frontal gyrus significantly predicted sleep spindles amplitude and frequency measured on frontal and central electrodes.

Evaluation of collaterals: comparison between cerebral perfusion using 3D T2SL and FVH in unilateral internal carotid artery stenosis
Xinbo Xing^{1,2}, Ting Wang¹, Jinhao Lv¹, Xiaoxiao Ma¹, Jiafei Yang², Lin Ma¹, and Xin Lou¹

¹Radiology, Chinese PLA general hospital, Beijing, People's Republic of China, ²Radiology, First affiliated hospital of Chinese PLA general hospital, Beijing, People's Republic of China

As a critical result in different researches the sign of FHV refers to the hemodynamic impairment and slow retrograde flow in leptomeningeal collaterals with or without good clinical outcome. We collected MR imaging data of 32 patients with unilateral ICA stenosis-occlusion who all underwent MR examinations by using 3D tASL perfusion imaging and T2-FLAIR. The tASL perfusion scores were compared between in FVH(-) group (14 patients) and FVH(+) group (18 patients), and there was no difference in the 2 groups. The result showed that 3D tASL perfusion MRI may be a useful non-invasive tool to identify the collateral flow.

Intracranial Vessel Analysis (IVA): A Toolkit for Semi-Automatic Morphological Quantification of Intracranial Atherosclerotic Plaque
Feng Shi¹, Zhangbin Yi², Qi Yang^{1,3}, Debiao Li¹, and Zhaoyang Fan¹

¹Biomedical Imaging Research Institute, Cedars Sinai Medical Center, Los Angeles, CA, United States, ²Electrical and Computer Engineering, University of Michigan, MI, United States, ³Department of Radiology, Xuanwu Hospital, Beijing, People's Republic of China

Intracranial atherosclerosis is a disease in which a sticky substance called plaque builds up inside the arteries. In practice, plaque analysis based on high resolution MRI is largely conducted manually by neuroradiologists with qualitative results. In this study, we propose a framework for intracranial vessel analysis (IVA), for semi-automatic morphological quantification of intracranial atherosclerotic plaque. Briefly, the framework includes functions of vessel path tracking, 3D MPR, vessel wall segmentation, measurement calculation, and report generation, with minimal user intervention required. Experiments show that plaque existence and location could be easily determined from the resulting vessel wall measures.

ICA-based overt speech artifact removal leads to improved estimation of deconvolution-based hemodynamic response function in aphasics
Venkatagiri Krishnamurthy^{1,2}, Lisa C. Krishnamurthy^{2,3}, Michelle L. Benjamin⁴, Kaundinya Gopinath⁵, and Bruce A. Crosson^{1,2,6}

¹Dept. of Neurology, Emory University, Atlanta, GA, United States, ²Center for Visual and Neurocognitive Rehabilitation, Atlanta VAMC, Decatur, GA, United States, ³Dept. of Physics & Astronomy, Georgia State University, Atlanta, GA, United States, ⁴University of Florida, Gainesville, FL, United States, ⁵Dept. of Radiology & Imaging Sciences, Emory University, Atlanta, GA, United States, ⁶Dept. of Psychology, Georgia State University, Atlanta, United States

Overt speech task functional Magnetic Resonance Imaging (fMRI) paradigms are very attractive to study aphasic patients, but are also plagued by task-correlated motion (TCM). Speech involves movements of the mouth and soft palate, and causes a change in air volume around these areas leading to localized motion and susceptibility artifacts. These artifacts become more severe in patients with Aphasia. The goal of this study is to utilize existing FSL-based semi-automated ICA tools, and optimize them to go beyond removing standard fMRI artifacts by also mitigating TCM artifacts to obtain meaningful hemodynamic response function (HRF) in aphasic patients. Our preliminary results to utilize ICA for TCM-based artifact removal is promising as evidenced by the improved sensitivity and specificity, but needs further optimization. Optimal denoising of overt speech task fMRI in aphasic patients will also help us to delineate their task-based networks in an effort to monitor plastic changes due to language behavior interventions.

Improved Visualization and Measurement of Intracranial Aneurysmal Walls: Comparison between 7T and 3T Black-blood MRI.

Zihao Zhang¹, Zhaoyang Fan², Chengcheng Zhu³, Xinke Liu⁴, Qi Yang^{2,5}, Xianchang Zhang^{1,6}, Qingle Kong^{1,6}, Jing An⁷, and Lin Chen^{1,6}

¹State Key Laboratory of Brain and Cognitive Science, Beijing MR Center for Brain Research, Institute of Biophysics, Chinese Academy of Sciences, Beijing, People's Republic of China, ²Biomedical Imaging Research Institute, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ³Department of Radiology and Biomedical Imaging, University of California San Francisco, San Francisco, CA, United States, ⁴Department of Interventional Neuroradiology, Beijing Neurosurgical Institute and Beijing Tiantan Hospital, Beijing, People's Republic of China, ⁵Xuanwu Hospital, Beijing, People's Republic of China, ⁶University of Chinese Academy of Sciences, Beijing, People's Republic of China, ⁷Siemens Shenzhen Magnetic Resonance Ltd., Shenzhen, People's Republic of China

Black-blood MRI (BB-MRI) has been used to evaluate the walls of intracranial aneurysms at both 3T and 7T. However, there is no quantitative comparison between the two field strengths in terms of delineation quality of aneurysmal wall by using BB-MRI. In this study, we analyzed black-blood images acquired from the same group of patients at both 7T and 3T. Higher wall-to-lumen signal ratio (WLSR) and lower inside wall thickness (IWT) were obtained from 7T black-blood images. Our results suggest that 7T BB-MRI can provide improved visualization and measurement of intracranial aneurysmal walls.

Comparative study of zero TE ASL MRA and 3D-TOF MRA in diagnostic value of cerebral arteriovenous malformations at 1.5T

Juan Huang¹, Yan Song, Peng Qi, Sheng Jiao, Hong Wang, Min Chen, and Bing Wu¹Beijing Hospital, Beijing, People's Republic of China

3D TOF MRA is susceptible to hemodynamic artifacts and is not sensitive to the slow blood flow, which results in the unsatisfied image quality for the diagnosis of AVMs. So we compared the use of zero TE ASL MRA (zTE MRA) and traditional 3D-TOF MRA in assessment of AVMs at 1.5T, taking DSA as standard. It was demonstrated that ASL MRA features significantly better consistency with DSA for AVMs as compared to TOF. In detail, zTE MRA can demonstrate the size, internal details, the feeding arteries and draining veins more clearly and accurately compared with TOF MRA.

Computer 79

A preliminary study on the amplitude of low frequency fluctuations in CADASIL

Mengxing Wang¹, Jingjing Su², Jilei Zhang¹, Hui Zhang¹, Jian-ren Liu², and Xiaoxia Du*¹

¹Shanghai Key Laboratory of Magnetic Resonance and Department of Physics, School of Physics and Materials Science, East China Normal University, Shanghai, People's Republic of China, ²Department of Neurology and Jiuyuan Municipal Stroke Center, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, People's Republic of China

The purpose of this study was to investigate spontaneous low-frequency fluctuations in CADASIL patients during resting-state fMRI scans. Eleven patients (aged, 33-66 years, 6 female) and 11 age- and gender-matched healthy controls were recruited. Amplitude of low-frequency fluctuation (ALFF) was calculated to measure spontaneous brain activity. The results showed that CADASIL patients exhibited significantly decreased ALFF in the bilateral precuneus, and increased ALFF in the midbrain/ pons, the insula/ temporal pole, and the anterior cingulate gyrus/ corpus callosum. Our study first provides empirical evidence for altered spontaneous neuronal activity in CADASIL patients.

Analysis of capillary permeability index and stiffness variation during Ischemic Stroke: A first step towards evaluation of compressibility and neurodegenerative changes in Brain MRE

Raghu Prasad¹, Jaganathan Vellagoundar², and Kathryn M McMillan³¹GE Healthcare, Bangalore, India, ²GE Healthcare, India, ³GE Healthcare, Milwaukee, WI, United States

Evaluation of compressibility and neurodegenerative changes is critical for planning the therapy for ischemic stroke disorders. A key factor that was not analyzed till date is the capillary permeability of blood-brain-barrier (BBB) perturbations and localized mechanical degenerative changes inside the infarct region during ischemic stroke. Our results clearly indicate a decrease in stiffness of stroke-affected infarct tissue. CPI was observed to be less in the weak BBB regions. The results demonstrate through CP and stiffness maps that extent of tissue integrity that is degraded inside the infarcted region can be assessed efficiently

Computer 82

Accelerated Time Resolved Phase Contrast Cerebral MRA to Evaluate Pulse Wave Velocity

Tzu Cheng Chao^{1,2}, Yu-Chia Cheng³, Wen-Chau Wu^{4,5}, Hsu-Hsia Peng⁶, Tzu-Chao Chuang⁷, Hsiao-Wen Chung^{5,8}, Teng-Yi Huang⁹, and Yi-Jui Liu³

¹Department of Computer Science and Information Engineering, National Cheng Kung University, Tainan, Taiwan, ²Institute of Medical Informatics, National Cheng Kung University, Tainan, Taiwan, ³Department of Automatic Control Engineering, Feng-Chia University, Taichung, Taiwan, ⁴Graduate Institute of Oncology, National Taiwan University, Taipei, Taiwan, ⁵Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan, ⁶Department of Biomedical Engineering and Environmental Sciences, National Tsing Hua University, Hsinchu, Taiwan, ⁷Department of Electrical Engineering, National Sun Yat Sen University, Kaohsiung, Taiwan, ⁸Department of Electrical Engineering, National Taiwan University, Taipei, Taiwan, ⁹Department of Electrical Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan

Time-resolved PCMRI has been applied to measure pulse wave velocity (PWV) for the assessment of aortic stiffness. However, longer scan time hinders its practice to achieve a high spatial and temporal resolution scan, especially required for the arteries inside of the head and neck. In the present work, an accelerated Time-resolved PCMRA was implemented to shorten scan time. The reconstruction combines temporal strategy and self-reference information to retain reasonable imaging quality. The results suggest that the proposed method differentiate PWV delay time from Common-Carotid artery to Middle-Cerebral arteries via Internal-Carotid artery with good quality within a 10-minute scan.

Accelerated Intracranial Vessel Wall Imaging using Compressed Sensing

Chengcheng Zhu¹, Bing Tian², Sinyeob Ahn³, Esther Raithel⁴, Gerhard Laub³, and David Saloner¹

¹Radiology, University of California, San Francisco, San Francisco, CA, United States, ²Radiology, Changhai Hospital, Shanghai, People's Republic of China, ³Siemens Healthcare, CA, United States, ⁴Siemens Healthcare, Erlangen, Germany

Current 3D black-blood high-resolution MRI (0.4-0.6mm isotropic) of intracranial vessel wall is limited by long scan times (~10 minutes). This study implemented a compressed sensing SPACE (CS-SPACE) sequence to reduce the scan time. The scan and reconstruction parameters were optimized in volunteers and then validated in patients. The optimized CS-SPACE protocol achieved good image quality and reliable vessel area measurements compared with SPACE, with a 37% time reduction. 0.5mm isotropic resolution can be achieved in <7 minutes, and 0.6mm³ is possible in 4 minutes. This fast intracranial vessel wall technique has potential for use in a clinical setting.

A time efficient, high resolution 3D vessel wall MRI (vwMRI) of the head and neck vessels in a single scan

Seong-Eun Kim¹, J Rock Hadley¹, Michael J Beck¹, J Scott McNally¹, Adam DeHavenon², Bradley D Bolster, Jr.³, Gerald S Treiman⁴, and Dennis L Parker¹

¹UCAIR, Department of Radiology and Imaging Sciences, University of Utah, Salt Lake City, UT, United States, ²Department of Neurology, University of Utah, ³Siemens Healthcare, ⁴Department of Veterans Affairs, VASLCHCS

Vessel wall MRI(vwMRI) increases diagnostic accuracy for stroke etiologies without overt luminal irregularities, such as mild atherosclerosis, subtle dissection, or vasculitis. Prior vwMRI research has focused on the head or neck in isolation. We developed a set of two neck-shape-specific(NSS) coil that fit two different neck sizes and configured them to integrate with the existing commercial head coils. The purpose of this work was to develop a 3D vwMRI protocol, leveraging the NSS coil array, which permits simultaneous imaging of the head and neck vessels in a single scan. By allowing an efficient examination and identifying patients at high risk of future recurrent stroke, this technique will enable detection of cryptogenic stroke sources and optimal personalized management of vascular disease.

Non-invasive MR Thermometry in a Non-human Primate Model of Acute Ischemic Stroke

Seena Dehkharghani¹, Candace Fleischer², Deqiang Qiu³, and Frank Tong⁴

¹Radiology, New York University, New York, NY, United States, ²Radiology and Imaging Sciences, Emory University, Atlanta, GA, United States, ³Radiology, Emory University, Atlanta, GA, United States, ⁴Radiology, Emory University

Temperature dysregulation is deeply implicated in potentiation of cerebrovascular ischemia. We present a multi-phasic, MR thermographic study in a non-human primate (NHP) model of MCA infarction, hypothesizing detectable brain temperature disturbances and brain-systemic temperature decoupling. Successful physiologic and continuous post-ischemic cerebral MR thermography was conducted, and prescribed in an NHP infarction model to facilitate translatability. The results confirm hypothesized temperature disturbance and decoupling of physiologic brain-systemic temperature gradients. These findings inform a developing paradigm of brain thermoregulation, and the applicability of brain temperature as a neuroimaging biomarker in CNS injury.

Spectral Diffusion IVIM Analysis of Enlarged Perivascular Spaces in Cerebral Small Vessel Disease

Sau May Wong¹, Jacobus F.A. Jansen¹, C. Eleana Zhang², Julie Staals², Paul A.M. Hofman¹, Robert J. van Oostenbrugge², and Walter H. Backes¹

¹Radiology and Nuclear Medicine, Maastricht University Medical Centre, Maastricht, Netherlands, ²Neurology, Maastricht University Medical Centre, Maastricht, Netherlands

The conventional IVIM model assumes a two-compartment model; this might not apply for regions with enlarged perivascular spaces (PVS) in cerebral small vessel disease (cSVD). Regularized non-negative least squared was used to deconvolve the IVIM signal in multiple diffusion components. Sixty-three cSVD patients and thirty-five controls received IVIM imaging and visual scoring of enlarged PVS. An additional component to the assumed parenchymal and perfusion components was revealed. We show that the fraction of this component is related to the amount of scored enlarged PVS. Quantifying PVS is a time-consuming process and this method might aid the development of automatic quantification.

Triple Magnetic Resonance Angiography (triple-MRA) for planning of Gamma Knife Radiosurgery of brain arteriovenous malformations

Alvaro Rojas Villabona^{1,2}, Magdalena Sokolska^{3,4}, Enrico De Vita⁴, Mary Murphy², Thomas Solbach⁵, Joan Grieve², Prem Rangi⁵, Yuriko Suzuki⁶, Matthias JP Van Osch⁶, David Atkinson⁷, Emma Biondetti³, Karin Shmueli³, Xavier Golay⁴, Ian Paddock¹, Neil Kitchen², and Hans Rolf Jäger^{4,5}

¹The Gamma Knife Centre at Queen Square, National Hospital for Neurology and Neurosurgery, London, United Kingdom, ²Department of Neurosurgery, National Hospital for Neurology and Neurosurgery, London, United Kingdom, ³Medical Physics and Biomedical Engineering, University College London, London, United Kingdom, ⁴Academic Neuroradiological Unit, Department of Brain Repair and Rehabilitation, Institute of Neurology, University College London, London, United Kingdom, ⁵The Lysholm Department of Neuroradiology, National Hospital for Neurology and Neurosurgery, London, United Kingdom, ⁶C. J. Gorter Center for High Field MRI, Department of Radiology, Leiden University Medical Center, Leiden, Netherlands, ⁷Centre for Medical Imaging, University College London, London, United Kingdom

This study investigates whether a combination of three MRA techniques, referred to as triple-MRA, could be used as an alternative to DSA for visualisation and delineation of brain AVMs for GKR targeting. The AVMs of 13 patients undergoing GKR were delineated using triple-MRA and the resultant target volumes were compared to the radiosurgical targets generated by the neurosurgical team using DSA and volumetric contrast T1/T2 imaging. Target volumes obtained using triple-MRA are comparable to target volumes obtained with DSA and used for delivery of GKR. In conclusion, triple-MRA is a robust method for non-invasive identification and delineation of brain AVMs.

4723

Susceptibility based characterization of brain arteriovenous malformations

Till M. Schneider^{1,2}, Markus Möhlenbruch¹, Sebastian Schmitter^{3,4}, Mark Ladd³, Heinz-Peter Schlemmer², Martin Bendszus¹, and Sina Straub³

¹Department of Neuroradiology, Universityhospital Heidelberg, Heidelberg, Germany, ²Department of Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany, ³Department of Medical Physics in Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany, ⁴Physikalisch-Technische Bundesanstalt (PTB), Braunschweig und Berlin, Germany

Brain arteriovenous malformations (bAVM) are congenital lesions detected incidentally or following symptomatic events like hemorrhage, seizure or headache. In bAVM patients, the most feared complication is intracranial hemorrhage with a general risk ranging between 2-4%¹ and further functional and hemodynamic characterization of bAVMs may improve risk assessment and ultimately aid in patient management^{2,3}. In this study, bAVMs have been investigated using quantitative susceptibility mapping and phase contrast based flow measurements. Susceptibility across the bAVM nidus is studied in relation to flow characteristics.

Semi-automatic Analysis of Carotid Plaque Composition from Multicontrast Magnetic Resonance Imaging

Chien-Yuan Eddy Lin^{1,2}, Ai-Chi Chen¹, Liang-Yu Shyu³, Yen-Chien Wu⁴, David Yen-Ting Chen⁴, Ying-Chi Tseng⁴, and Chi-Jen Chen⁴

¹GE Healthcare, Taipei, Taiwan, ²GE Healthcare MR Research China, Beijing, People's Republic of China, ³Biomedical Engineering Department, Chung Yuan Christian University, Chungli, Taiwan, ⁴Department of Radiology, Taipei Medical University - Shuang Ho Hospital, New Taipei City, Taiwan

Accurate tracking of plaque composition would be very useful clinically to determine the status of atherosclerosis and to understand the potential risk under myocardial infarction, stroke, and peripheral vascular disease. We developed a semi-automatic software to evaluate the carotid plaque types using four contrast-weighted MRI (pre- and post-contrast T1-weighted, time-of-flight, T2-weighted). Working with the proposed software with the minimal operator input reduces the process time of plaque component identification and minimizes the possibility of random and systematic errors. As a result, proposed software is capable of assisting the radiologist/clinician in imaging interpretation and decision-making in managing carotid artery atherosclerosis.

Automatic Quantification of Haematoma and Surrounding Oedema in MRI of Acute Spontaneous Intracerebral Haemorrhage: Preliminary Results for the TICH-2 MRI Sub-study

Stefan Psczolkowski¹, Rebecca G. Gallagher^{2,3}, Zhe K. Law^{1,4}, Dewen Meng¹, David J. Swienton^{2,5}, Paul S. Morgan⁶, Philip M. Bath¹, Nikola Sprigg¹, and Robert A. Dineen¹

¹Division of Clinical Neuroscience, University of Nottingham, Nottingham, United Kingdom, ²Department of Neuroradiology, Nottingham University Hospitals, United Kingdom, ³Department of Radiology, Royal Derby Hospital, United Kingdom, ⁴Department of Medicine, National University of Malaysia, Malaysia, ⁵Imaging Department, Leicester Royal Infirmary, United Kingdom, ⁶Department of Medical Physics and Clinical Engineering, Nottingham University Hospitals, United Kingdom

In this work, we propose to take advantage of improved contrast seen on magnetic resonance (MR) images of patients with acute spontaneous intracerebral haemorrhage (SICH), and introduce an automated algorithm for haematoma and oedema segmentation from these images. To our knowledge, there is no previously proposed segmentation technique for SICH that utilises MR images directly. The method is based on k-means clustering of image intensities for haematoma segmentation and voxel-wise dynamic thresholding of hyper-intensities for oedema segmentation. Preliminary results using the Dice score metric to measure segmentation overlaps between labellings yielded by the proposed algorithm and five different expert raters show that our technique has the potential to be an effective way to automatically delineate haematoma and perihematomal oedema extent directly from MR images.

A Retrospective Study of Amide Proton Transfer Imaging in Acute Ischemic Stroke

Guodong Song¹, Min Chen¹, Chunmei Li¹, and Jinyuan Zhou²

¹Department of Radiology, Beijing Hospital, Beijing, People's Republic of China, ²Department of Radiology, Johns Hopkins University, BALTIMORE, MD

This study was performed to investigate the imaging features of Amide Proton Transfer (APT) MR imaging in different subtypes of acute ischemic stroke (AIS). By figuring out the detailed APTw features in AIS patients, it would be helpful for further clinical applications of APT MRI technique.

4727

Computer 95

Arterial transit time measured by multi-delay ASL perfusion for evaluating major cerebral artery stenosis/occlusive disease: correlation with 15O-H₂O and 15O₂ gas PET-CBF and OEF

Kayo Takeuchi¹, Makoto Isozaki², Masayuki Kanamoto¹, Yoshifumi Higashino², Hidehiko Okazawa³, Kenichiro Kikuta², R Marc Lebel⁴, and Hirohiko Kimura¹

¹Department of Radiology, University of Fukui, Fukui, Japan, ²Department of Neurosurgery, University of Fukui, Fukui, Japan, ³Biomedical Imaging Center, University of Fukui, Fukui, Japan, ⁴GE Healthcare, Calgary, Canada

Positron emission computed tomography (PET) is used for evaluating cerebral hemodynamic ischemic stages in patients with major cerebrovascular stenosis/occlusion for treatment indication. Using a rapid, low-resolution pre-scan method, arterial transit time (ATT) and corrected cerebral blood flow (CBF) could be obtained, even in the immediate clinical setting. This study aimed to clarify whether ATT is hemodynamically related to misery perfusion stratified with ¹⁵O-H₂O/¹⁵O₂-gas PET data. There was a significant correlation between ASL and PET CBF before and after ATT correction ($r^2=0.27, 0.55$). ATT also significantly correlated with PET-OEF ($r^2=0.11$) and is a useful parameter to classify cerebral ischemia.

Imaging changes in cardiorespiratory pulsation amplitude of the brain during breathhold - an MREG-study.

Lauri Raitamaa¹, Vesa Korhonen¹, and Vesa Kiviniemi¹

¹OFNI/Radiology, Oulu University Hospital, Oulu, Finland

Glymphatic pulsation mechanisms clear the brain by using physiological pulsations to drive CSF through the brain tissue. Magnetic resonance encephalography (MREG), an ultra-fast inverse imaging technique, was recently able to map three basic mechanisms driving the glymphatic brain clearance; arterial pulsations, respiratory venous pulses and slow vasomotor waves. In this study we demonstrate that the MREG can also detect changes in the amplitudes of the pulsations driving the clearance. The mapping of the physiological pulsation amplitude changes can be used to quantify changes in glymphatic clearing mechanisms that precede neurodegeneration.

Cardiac-induced pulsatility of blood flow resolved in sub-millimeter cerebral veins using phase contrast MRI at 7 Tesla
Ian D Driver¹, Fabrizio Fasano², and Richard G Wise¹

¹CUBRIC, School of Psychology, Cardiff University, Cardiff, United Kingdom, ²Siemens Healthcare Ltd, Frimley, Camberley, United Kingdom

We report the first measurement of venous flow pulsatility in cerebral veins with sub-millimeter diameters using phase contrast MRI. This work exploits the increased signal and finer spatial resolution available at 7 Tesla, over lower field strengths. We suggest that the observed venous pulsatility is a passive response to intracranial pressure changes caused by arterial pulsatility. These measurements may be applied to pathology in which there is compromised venous flow, extending such investigations to the smaller cerebral veins and offering a better understanding of the temporal dynamics of cerebral venous flow.

Cross-validation of T₂-prepared bSSFP blood oximetry *in vivo*
Ana E Rodríguez-Soto¹, Michael C Langham¹, and Felix W Wehrli¹

¹Department of Radiology, University of Pennsylvania, Philadelphia, PA, United States

Susceptometry-based oximetry is a well-established, robust method for quantifying hemoglobin oxygen saturation (HbO₂) *in vivo*; but the method is somewhat limited by the orientation of the vessel of interest relative to B₀. T₂-based oximetry, based on the dependence of blood water T₂ on HbO₂, provides greater flexibility with respect to vessel geometry. However, the measured T₂ critically depends on B₀ and sequence-specific imaging parameters. Here, a T₂-prepared bSSFP sequence and appropriate calibration curve were used to extract HbO₂ at the superior sagittal sinus and the results were compared to susceptometry-based oximetry. The agreement between both methods was excellent with 2% bias.

Dynamic frequency feedback to multiband (MB) EPI PCASL excitation, fat saturation, and labeling RF pulse frequency can improve spatial and temporal perfusion signal-to-noise ratio (sSNR and tSNR) and cerebral blood flow (CBF) measurement reproducibility of MB-EPI PCASL. Dynamic frequency feedback helps maintain optimal labeling efficiency, achieve stable fat saturation, and correct scanner drift during MB-EPI PCASL measurements.

Inversion Recovery Ultrashort Echo Time Imaging of Short T₂ Tissue Components in Ovine Brain: A Sequential D₂O Exchange Study

Shu-Juan Fan¹, Yajun Ma¹, Graeme M. Bydder¹, and Jiang Du¹

¹Dept. of Radiology, University of California, San Diego, San Diego, CA, United States

Myelin produces ultrashort-lived MRI signals, and cannot be directly imaged using conventional MRI sequences that typically have TEs of several milliseconds or longer. This study explored the potential of inversion recovery ultrashort echo time (IR-UTE) sequences in direct myelin imaging in an ovine brain D₂O exchange model. The IR-UTE signals survived D₂O exchange. Myelin T₂* was measured to be 200-300 μs both before and after exchange. These results support myelin to be the major source of the ultrashort T₂* signals seen on IR-UTE images, and IR-UTE sequence as a tool for assessing myelin loss in multiple sclerosis and other diseases.

Superior sagittal sinus venous oxygen saturation based on fully automated MR susceptometry : effects of slice dependent even-odd echo discrepancy and vascular angle correction

Chou-Ming Cheng^{1,2}, Tzu-Chen Yeh^{3,4}, Jen-Chuen Hsieh^{2,4}, and Hsiao-Wen Chung¹

¹Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan, ²Department of Medical Research, Taipei Veterans General Hospital, Taipei, Taiwan, ³Department of Radiology, Taipei Veterans General Hospital, Taipei, Taiwan, ⁴Institute of Brain Science, National Yang-Ming University, Taipei, Taiwan

Venous oxygen saturation (SvO₂) for estimation of global cerebral metabolic rate of oxygen is measured using MR susceptometry from the phase information obtained with multi-echo gradient-echo imaging. Automatic selection and segmentation of the superior sagittal sinus is performed with slice dependent even-odd discrepancy to avoid operator dependency. Results from 12 healthy subjects suggested that phase values of the vessel showing minimal even-odd echo discrepancy could be used as a useful information guiding selection of the appropriate vessel segment for SvO₂ estimations by taking into consideration the three dimensional vasculature.

MRI submerging into The Big Blue: A comparative 3D-pCASL and IVIM-MRI brain perfusion study to elucidate circulatory adaptation during prolonged freediving

Vera Catharina Keil¹, Lars Eichhorn², Burkhard Mädler³, Jürgen Gieseke³, Frank Träber¹, Wolfgang Block¹, Martin Alois Sprinkart¹, Andreas Müller¹, Christine Schneider⁴, Lukas Scheef¹, Hans Heinz Schild¹, Dariusch Reza Hadizadeh¹, and Elke Hattingen¹

¹Department of Radiology, University Hospital Bonn, Bonn, Germany, ²Department of Anesthesiology, University Hospital Bonn, Bonn, Germany, ³Clinical Science Department, Philips Healthcare, Germany, ⁴Department of Neurology, University Hospital Bonn, Bonn, Germany

Freedivers can endure severe hypoxemia during breathhold without any apparent neurological deficit. Little is known on how brain circulation adapts to deliberate breathhold. We examined 14 experienced freedivers during breathholds of 5 to 7.5 minutes at a 3T MRI applying 3D-pCASL and IVIM-MRI sequences to reveal dynamic alterations of cerebral blood flow (rCBF) and in order to elucidate the relationship of rCBF and perfusion fraction (PF) of IVIM-MRI. rCBF increased to 3.2-fold the baseline levels and negatively correlated to blood oxygen levels, but not to PF, which initially dropped during breathhold and therefore appears to represent another underlying physiological mechanism.

A method for near-realtime automated segmentation of thalamic nuclei

Francis Tyson Thomas¹, Jason Su², Brian K Rutt², and Manojkumar Saranathan³

¹Electrical and Computer Engineering, Univ. of Arizona, Tucson, AZ, United States, ²Radiology, Stanford University, Stanford, CA, United States, ³Medical Imaging, Univ. of Arizona, Tucson, AZ, United States

Thalamic nuclei are often hard to visualize on most anatomical sequences. White-matter-nulled MPRAGE imaging provides sufficient intra-nuclear contrast to enable manual segmentation, which is very tedious. We have developed fast multi-atlas based segmentation schemes that can provide accurate segmentation of all the major thalamic nuclei in under 15 minutes.

Computer 106

Small vessel specific cerebrovascular reactivity with 7 tesla 2D Qflow MRI.

Lennart J. Geurts¹, Alex Bhogal¹, Jeroen C. W. Siero^{1,2}, Geert Jan Biessels³, and Jaco J. M. Zwanenburg¹

¹Radiology, UMC Utrecht, Utrecht, Netherlands, ²Spinoza Center for Neuroimaging, Amsterdam, Netherlands, ³Brain Center Rudolf Magnus, UMC Utrecht, Utrecht, Netherlands

We aimed to measure cerebrovascular reactivity (CVR) specifically at the level of the superficial perforating arteries with 7T 2D Qflow, to develop a method to assess small vessel function for cerebral small vessel disease research. 7T 2D Qflow acquisitions through the semi oval center (CSO) and through the medial cerebral artery (M1) were acquired at baseline and during hypercapnia. CVR_{M1} corresponded to CVR values from Qflow literature and, while an order of magnitude smaller, CVR_{CSO} corresponded to CVR values from ASL literature. This shows proof of concept that CVR of perforating arteries can be measured using 7T 2D Qflow.

Computer 107

Segmented EPI readout Variable Flip-angle Magnetization Transfer (EP-vfMT) imaging for 7 T quantitative MT (qMT) Imaging

Se-Hong Oh^{1,2} and Mark J. Lowe¹

¹Imaging Institute, Cleveland Clinic Foundation, Cleveland, OH, United States, ²Department of Biomedical Engineering, Hankuk University of Foreign Studies, Yongin, Korea, Republic of

Because of the much higher SAR and longer acquisition time, patient studies using qMT at UHF have not been clinically feasible. In this work, we demonstrated a new approach (EP-vfMT) for whole brain 7T qMT data in a clinically reasonable time. EP-vfMT provides similar image quality to that obtained with conventional MT imaging, and shortens the scan time by utilizing segmented EPI readout and avoiding from SAR limitation. EP-vfMT generates qMT map in reasonable scan time and it exhibits similar myelin density distribution with qMT result from vdMT and aMWF map from ViSta. Moreover, it maintains sensitivity to MS lesions.

Parallel transmission (pTx) on an in-vivo human brain at 7T: a new approach using global B₁ coefficient template

Se-Hong Oh^{1,2}, Tiejun Zhao³, Ken Sakie¹, Stephen E. Jones¹, and Mark J. Lowe¹

¹Imaging Institute, Cleveland Clinic Foundation, Cleveland, OH, United States, ²Department of Biomedical Engineering, Hankuk University of Foreign Studies, Yongin, Korea, Republic of, ³Siemens Healthcare, New York, NY, United States

Improving B₁-uniformity by calibration procedure is crucial for the pTx imaging and commonly individual B₁ coefficient estimation is conducted in the beginning of each patient scan protocol. However, B₁ calibration procedure increase the scan time by approximately 10~15 mins increasing discomfort to the patient. Here we propose using global B₁ coefficient template to reduce scan time while maintaining acceptable B₁ profile. The approach using global B₁ coefficient template is assumed to have limited inter-individual variation of B₁ coefficient between subjects. We demonstrate the feasibility of scan with global B₁ coefficient template and provide a perception of in-vivo scan with pTx.

Toward Real Time Estimation and Quality Assurance for Myelin Water Mapping in the Human CNS

Khader M Hasan¹, Refaat E Gabr¹, John A Lincoln², and Ponnada A Narayana¹

¹*Diagnostic and Interventional Radiology, University of Texas Health Science Center at Houston, Houston, TX, United States*, ²*Neurology, University of Texas Health Science Center at Houston, Houston, TX, United States*

Reliable *in vivo* quantification and visualization of myelin spatio-temporal changes in the developing and aging human central nervous system (CNS) would help provide important surrogate markers of white matter integrity. However, high resolution whole brain myelin water fraction (MWF) mapping methods remain challenging and are not well-standardized and are not widely adopted due to ill-posed solutions of the sum-of-exponents problem in the presence of noisy measurements and excessive computation time due to iterative solutions. In this work, we report a rapid method to initialize the solution of the bi-exponential multi-compartment fit which was used along with a host of quality assurance measures to speed up the estimation of the MWF and corresponding compartmental T2 relaxation times using an improved and regularized non-negative least-squares (rNNLS). The sensitivity of the method to signal-to-noise ratio (SNR) and different values of MWF was investigated using a digital phantom. This method was applied to healthy and multiple sclerosis (MS) patients. Our analysis strategy accelerated the accurate mapping of high resolution MWF in the entire human brain in seconds and provided the spatial variability MWF across the corticospinal tract (CST) and callosal pathways.

$\Delta R_{1\rho}$, a potential indication for myelin concentration in white matter?

Ping Wang¹, Richard Dortch¹, and John C. Gore¹

¹*Radiology and Radiological Sciences, Vanderbilt University Institute of Imaging Science, Nashville, TN, United States*

Previous studies have demonstrated that at high fields (3T and beyond), the difference of $R_{1\rho}$ between low and high spin-locking fields ($\Delta R_{1\rho}$) may reflect chemical exchange processes in biological tissues. This study aimed to investigate the possibility of using $\Delta R_{1\rho}$ to assess the content of exchangeable protons in myelin in white matter by comparing $\Delta R_{1\rho}$ with PSR (macromolecular to free pool size ratio from magnetization transfer imaging). The results show that $\Delta R_{1\rho}$ and PSR have a much stronger correlation in white matter than in gray matter, inferring that $\Delta R_{1\rho}$ might have a potential to evaluate myelin integrity.

4742

Computer 111

Comparison of $R_{1\rho}$ dispersion in human brain between 3T and 7T

Ping Wang¹, Henry Zhu¹, and John C. Gore¹

¹*Radiology and Radiological Sciences, Vanderbilt University Institute of Imaging Science, Nashville, TN, United States*

Previous studies have indicated that $R_{1\rho}$ ($= 1/T_{1\rho}$) dispersion may be dominated by chemical exchange processes at higher fields, and the dispersion may be used to quantify exchange processes between water and labile protons, mainly amides and hydroxyls. At 3T some biological tissues with high macromolecular protein content may demonstrate a considerable dispersion, but fat and water rich tissues typically have a negligible $R_{1\rho}$ dispersion. In this study, we observed that the degree of $R_{1\rho}$ dispersion in white matter at 7T was more than three times the dispersion at 3T, confirming that chemical exchange is a major contribution to $R_{1\rho}$ and suggesting $R_{1\rho}$ dispersion at higher fields may help to characterize tissue physicochemical properties.

COntstrained Data Extrapolation (CODE): A New Approach for High Resolution MR Angiographic Image Reconstruction.

Yang Song¹, Ehsan Hamtaei², Guang Yang¹, Haibin Xie¹, and Mark Haacke^{1,2,3}

¹*Shanghai Key Laboratory of Magnetic Resonance, East China Normal University, Shanghai, People's Republic of China*, ²*Magnetic Resonance Innovations, Inc., Detroit, MI, United States*, ³*Radiology, Wayne State University, Detroit, MI, United States*

We propose a "COntstrained Data Extrapolation" (CODE) algorithm to reconstruct high-resolution MRA images from k-space with a lower resolution thereby accelerating acquisition of the data. We found that CODE can estimate a 50% (70%) stenosis of a vessel with a diameter equal to 7 (10) pixels in the high-resolution image to within 5% of the correct result when the SNR=4:1 or better. Both phantom simulations and in-vivo 3D contrast enhanced MRA data demonstrate that CODE is robust to noise and can be used to speed up conventional data acquisition by a factor of four.

Non-Invasive Cerebrovascular Pulsatility Measurement via Cardiac Sorting of BOLD Data: An Investigative Study Using Exercise-Induced Hypotension in Adolescents

Athena Theyers^{1,2,3}, Benjamin Goldstein^{2,3}, Arron Metcalfe^{2,3}, Andrew Robertson^{2,3}, and Bradley MacIntosh^{1,2,3}

¹*University of Toronto, Toronto, ON, Canada*, ²*Sunnybrook Research Institute, Toronto, ON, Canada*, ³*Heart & Stroke Foundation Canadian Partnership for Stroke Recovery, Toronto, ON, Canada*

Arterial pulsatility increases with age and is linked to small vessel damage and neurodegeneration. Our group has developed a method that fits a pulsatility model to BOLD temporal volumes based on their cardiac cycle position. We test this method in a healthy adolescent group before and after a physiological stressor, i.e. 20 minutes of moderate intensity exercise. Brain pulsatility was significantly lower in BOLD scans taken 20 minutes after exercise cessation, supporting the viability of this method to track brain arterial stiffness non-invasively.

Computer 119

Quantitative T1 mapping and somatotopic organization of the cerebellum at 7T : is there a link?

Yohan Boillot¹, Pierre-Louis Bazin², Rolf Gruetter^{1,3,4}, and Wietske Van der Zwaag^{5,6}

¹Laboratory of Functional and Metabolic Imaging, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ²Department of Neurophysics, Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ³Department of Radiology, University of Lausanne, Lausanne, Switzerland, ⁴Department of Radiology, University of Geneva, Geneva, Switzerland, ⁵Biomedical Imaging Research Center, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ⁶Spinoza Centre for Neuroimaging, Amsterdam, Netherlands

In this study, the spatial relationship between the somatotopy and the pattern of myelination (as measured by quantitative T_1 -maps) in the cerebellum was investigated. Subject-specific surfaces were generated on which were mapped T_1 values and somatotopic maps. Consistent somatotopic gradients organized through several lobules were present in the anterior and posterior lobes. Despite being more complex, changes of T_1 values across the cerebellar surface were also observed and showed a similar orientation as the somatotopic organization. This study showed the potential structure-function relationship of the cerebellum observed at macroscale level.

Slice Realignment for Motion-Corrupted Stacks of Short-Axis Cine Cardiac MR Images based on 3D Probabilistic Edge Maps

Giacomo Tarroni¹, Ozan Oktay¹, Andreas Schuh¹, Wenjia Bai¹, Antonio de Marvao¹, Declan O'Regan¹, Stuart Cook¹, and Daniel Rueckert¹

¹Imperial College London, London, United Kingdom

Short-axis cine cardiac MR image stacks are acquired during multiple breath-holds, which often causes a misalignment of several slices. We propose a technique for in-plane spatial realignment of motion-corrupted short-axis slices which uses probabilistic edge maps of the myocardium (generated with decision forests) as input to image registration. The proposed technique was quantitatively tested on a dataset of motion-free stacks artificially corrupted by in-plane motion. Overlap measures such as the Dice coefficient - computed on myocardial masks segmented respectively on motion-free, motion-corrupted and motion-corrected stacks - suggest that the proposed technique is able to correctly compensate for slice misalignment.

Semi-Automatic Ejection Fraction Calculation from Cardiac Low-Rank Tensor Images Based on Unsupervised Machine Learning

Zihao He^{1,2}, Anthony G. Christodoulou^{1,3}, Hua Guo², and Debiao Li^{1,4}

¹Biomedical Imaging Research Institute, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ²Center for Biomedical Imaging Research, Department of Biomedical Engineering, School of Medicine, Tsinghua University, Beijing, People's Republic of China, ³Cedars-Sinai Heart Institute, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ⁴Department of Bioengineering, University of California Los Angeles, Los Angeles, CA, United States

Calculation of the ejection fraction from cardiac cine MR images requires segmenting multiple images of the left ventricle. This process, which is often performed manually, is time-consuming and observer-dependent. In this work, an unsupervised machine learning algorithm, combining hidden Markov random field and optical flow, has been proposed to perform semi-automatic tissue segmentation on T1/T2-weighted low-rank tensor images that have a built-in feature space due to low-rank factorization performed during image reconstruction. The segmentation results then allow automatic EF calculation. Demonstrated results have higher efficiency and similar accuracy compared with manual segmentation, and were stable with respect to different initializations.

Computer 4

Non-rigid Groupwise Image Registration for Myocardial Strain Quantification from High-Resolution 3D Tagging

Valery Vishnevskiy¹, Christian Stoeckl¹, and Sebastian Kozerke¹

¹Institute for Biomedical Engineering, ETH Zurich, Zurich, Switzerland

Cardiac motion can be efficiently assessed using 3D-tagged MR sequences for diagnostic purposes. However, there is a lack of robust post-processing tools to derive regional motion and strain data. Current registration methods tend to underestimate radial strain in the left ventricle. In order to provide accurate strain estimates we leverage temporal smoothness of displacements and low-rank structure of aligned images. The herein proposed method is 38% more accurate for radial strain, 27% for circumferential strain and 25% for longitudinal strain estimation than state-of-the-art registration implemented in Elastix while increasing computational speed by a factor of six.

Cardiac image acquisition by SENSE combined compressed sensing with three dimensional quantification

Jong-Hyun Yoon¹, Pan-ki Kim², Young-Joong Yang¹, Jinho Park³, Jin-Soo Kim¹, Byoung Wook Choi², and Chang-Beom Ahn¹

¹Department of Electrical Engineering, Kwangwoon University, Seoul, Korea, Republic of, ²Department of Radiology, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of, ³Brain Research Laboratory, Children's National Health System, Washington, DC, United States

SENSE combined compressed sensing technique is applied to multi-slice cardiac CINE imaging with breath holds. As to the compressed sensing, ITSC is used, which truncates small transformed coefficients in r-f domain to make data sparse, and it restores the measured data in k-t domain iteratively until the reconstructed images converge. Variation of ejection fraction (EF) is measured for two set of experiments, one from regenerated data set by resampling the original data set, and the other from real measurements. Using the variation of EF and normalized mean square error clinical usefulness of the technique is demonstrated.

4757

Motion tracking in cardiac MRI: Cine Watermark tracking of myocardial strain

Davis Marc Vigneault^{1,2,3}, Ronald J Beyers⁴, Chia Ying Liu², Alison J Noble¹, Thomas Denney⁴, and David A Bluemke²

¹Department of Engineering Science, University of Oxford, Oxford, United Kingdom, ²Radiology and Imaging Sciences, National Institutes of Health, Bethesda, MD, United States, ³Sackler School of Graduate Biomedical Sciences, Tufts University School of Medicine, Boston, MA, United States, ⁴Auburn University MRI Research Center, Auburn University, Auburn, AL, United States

Quantification of regional cardiac function is of central importance in cardiology, but has yet to be adopted into clinical practice due to limitations of the current techniques. Here we present a method requiring minimal human intervention for tracking "cine watermark" images, in which features have been encoded into the *phase image* of a cardiac cine series. The method employs nonlinear least squares optimization, which allows the sum of squared wrapped phase differences between patches in successive frames to be minimized globally across all frames, while regularizing over physically-motivated metrics. Preliminary results in healthy human volunteers show robust tracking.

Automated 4D Flow Conservation Utilizing Adjacency Matrices

Carson Anthony Hoffman¹, Gabe Shaughnessy¹, and Oliver Wieben¹

¹Medical Physics, University of Wisconsin Madison, Madison, WI, United States

4D flow magnetic resonance imaging (MRI) can provide comprehensive information on vessel anatomy and hemodynamics for complex vessel system. Adjacency matrices are often used in computer science to help simplify complex graphs into a binary encoded matrix. The adaptation of adjacency matrices to 4D flow MRI can help reduce the complexity for analysis by structuring the data into an efficient binary matrix. One application of this new analysis method allows for flow conservation to be completed for complex volumes at all junctions. The conservation of flow at every junction can then be used to find segments of potential erroneous measurements.

4759

Computer 8

MRI vessel slice tool visualization with an interactive 3-D display

Carson Anthony Hoffman¹, Eric Schrauben¹, and Oliver Wieben^{1,2}

¹Medical Physics, University of Wisconsin Madison, Madison, WI, United States, ²Radiology, University of Wisconsin Madison, Madison, WI, United States

The comprehensive information on vessel anatomy and hemodynamics presented by 4D Flow MRI can be difficult to visualize. We introduce a new viewing mode using a 'slice tool'. The use of this display algorithm can provide benefits for scalar visualization by preserving spatial location and avoiding ambiguities in cases of overlapping vessels. This novel approach can thus offer an improved understanding of complex hemodynamics within the body when used in conjunction with previously existing visualization methods eg. MIP images, pathline, and streamline visualizations.

SUPER-RESOLUTION RECONSTRUCTION OF LATE GADOLINIUM ENHANCEMENT CARDIOVASCULAR MAGNETIC RESONANCE IMAGES USING A RESIDUAL CONVOLUTIONAL NEURAL NETWORK

Archontis Giannakidis^{1,2}, Ozan Oktay³, Jennifer Keegan^{1,2}, Veronica Spadotto^{1,4}, Inga Voges¹, Gillian Smith¹, Iain Pierce¹, Wenjia Bai³, Daniel Rueckert³, Sabine Ernst¹, Michael A Gatzoulis¹, Dudley J Pennell^{1,2}, Sonya Babu-Narayan¹, and David N Firmin^{1,2}

¹NIHR Cardiovascular Biomedical Research Unit, Royal Brompton Hospital, London, United Kingdom, ²National Heart & Lung Institute, Imperial College London, London, United Kingdom, ³Biomedical Image Analysis Group, Imperial College London, London, United Kingdom, ⁴Department of Cardiac, Thoracic and Vascular Sciences, University of Padua

Late gadolinium enhancement cardiac magnetic resonance (LGE-CMR) has enabled the accurate myocardial tissue characterization. Due to practical considerations, the acquisition of anisotropic two-dimensional (2D) stack volumes, with low through-plane resolution, still prevails in the clinical routine. We propose a deep learning-based method for reconstructing a super-resolved three-dimensional LGE-CMR data-set from a low resolution 2D short-axis stack volume. The method directly learns the residuals between the high and low resolution images. Results on clinical data-sets show that the proposed technique outperforms the state-of-the-art with regard to image quality. The fast speed of our model furthers facilitates its adoption for practical usage.

Computer 13

A Novel 4D Semi-automatic Segmentation Algorithm for Whole-heart 3D Cine Magnetic Resonance Imaging

Ruizhi Liao¹, Danielle F. Pace¹, Andrew J. Powell², Polina Golland¹, and Mehdi Hedjazi Moghari²

¹Massachusetts Institute of Technology, Cambridge, MA, United States, ²Boston Children's Hospital, Boston, MA, United States

Three-dimensional (3D) time-resolved (cine) whole-heart magnetic resonance imaging promises to greatly facilitate comprehensive and evaluation of cardiac function and morphology. We present here a robust semi-automatic 4D segmentation algorithm, using patch-based volumetric segmentation and a temporal image registration method, to reduce the segmentation time of 3D cine datasets to less than 30 minutes and to enable wide clinical use. Resulting volumetric measurements of the left ventricle and right ventricle are aligned with measurements from the current clinical routine. By visualizing the anatomy and dynamics of the heart, we show that 3D cine datasets promise to enhance surgical planning for patients with complex congenital heart disease.

4765

Computer 14

Non-iterative model for synthetic image-based registration of MOLLI cardiac T1 mapping images

Laura Claire Saunders¹, Neil Stewart¹, David Kiely², Martin Graves³, Andy Swift¹, and Jim Wild¹

¹Academic Radiology, University of Sheffield, Sheffield, United Kingdom, ²Pulmonary Vascular Disease Unit, Sheffield Teaching Hospitals NHS Trust, ³University of Cambridge

Cardiac T1 maps rely upon the acquisition of spatially aligned images. When patients fail to maintain breath hold, respiratory motion can cause T1 map inaccuracies due to poor image alignment. In the method demonstrated here, images are registered by co-registration to synthetic images, which are created via a non-iterative, automatic, model-based method. This method is compared to an iterative registration method using an energy minimisation process for quantitative registration accuracy and speed. Both methods were found to significantly improve image registration. The resultant registrations from both methods did not significantly differ, however the non-iterative model-based method reduced processing time by 1/5th.

An MRI based High-Resolution Geometrical Framework to Quantify Left Ventricular Remodeling in Murine Model of Myocardial Infarction

Siamak Ardekani¹, Geoffrey Gunter¹, Jiadi Xu¹, Robert G Weiss², and Laurent Younes¹

¹Johns Hopkins University, Baltimore, MD, United States, ²Johns Hopkins Medical Institutions, Baltimore, MD, United States

Computational models of left ventricular (LV) geometry and function that characterize regional cardiac response to injury can provide valuable diagnostic and predictive information. We have developed a mathematical tool to non-rigidly match a high-resolution surface mesh of the LV geometry to a set of LV epi and endocardial contours that are extracted from cardiac MR. We have applied our algorithm on murine model of myocardial infarction to quantify cardiac remodeling process. This approach enables us to perform statistical analysis of LV 3D geometry and function using only sparse sets of 2D plane contours, therefore facilitating cross-subject examination of shape variation.

Texture analysis of native T1 mapping in dilated cardiomyopathy

Xiaoning Shao¹, Yingjie Sun¹, Yong Zhang¹, Jingliang Cheng¹, and Shaoyu Wang²

¹MRI, The first affiliated hospital of Zhengzhou University, Zhengzhou, People's Republic of China, ²MR, Siemens Healthcare Ltd, Shanghai, People's Republic of China

MR native T1 mapping technique was found have the ability of detecting diffuse myocardial fibrosis which was found in histological examination of dilated cardiomyopathy (DCM). Texture analysis of T1 mapping had been proved to be able to provide more information besides T1 value. We found several histogram parameters (statistical class of texture analysis) were significantly higher in DCM than that of healthy volunteers. The areas under the receiver operating characteristic curve of histogram parameters were calculated. The results indicate that texture analysis of T1 mapping may be helpful for the diagnosis of DCM.

Improving Precision of Arrhythmia-Insensitive Rapid Cardiac T1 Maps using a Non-Local Means Filter

Suvai Gunasekaran¹, KyungPyo Hong², Jeremy Collins², James Carr², and Daniel Kim^{1,2}

¹Biomedical Engineering, Northwestern University, Chicago, IL, United States, ²Radiology Department, Feinberg School of Medicine, Chicago, IL, United States

Compared with other investigations, images produced from arrhythmia-insensitive rapid (AIR) cardiac T₁ mapping pulse sequences contain significant random noise which limits the accuracy of quantitative measurements. Therefore, denoising filters were used to reduce noise present in the images. From our analysis, the non-local means filter was best able to reduce the amount of noise while still maintaining accurate T₁ measurement data.

Validation of dMRI-Derived Fiber Orientations Using PLI in Human Fetal Hearts

Feng Yang^{1,2}, YueMin Zhu², Gabrielle Michalowicz³, Yves Usson³, Laurent Fanton², Magalie Viallon^{2,4}, Patrick Clarysse², Pierre-Simon Jouk³, and Pierre Croisille^{2,4}

¹Department of Computer Science, School of Computer and Information Technology, Beijing Jiaotong University, Beijing, People's Republic of China, ²Univ.Lyon, INSA-Lyon, Université Claude Bernard Lyon 1, UJM-Saint Etienne, CNRS, Inserm, CREATIS UMR 5220, U1206, F-69621, LYON, France, Villeurbanne, France, ³Equipe DYCTIM, Laboratoire TIMC-IMAG, UMR5525 CNRS, Université Grenoble Alpes, La Tronche, France, France, ⁴Jean-Monnet University, Saint-Etienne, France, Saint-Etienne, France

To validate to what extent the fiber orientations derived from diffusion MRI (dMRI) reveal anatomical reality, polarized light imaging (PLI) allowing the fiber orientations of the human heart to be physically measured with high spatial resolution was used. The dMRI and PLI orientation measurements of the same hearts are then compared using a multimodal registration-based framework. Experimental results show that dMRI and PLI have similar variation patterns of elevation or azimuth angles, except that dMRI introduced a decrease of about 24° in transmural elevation angle range. No significant differences were observed on azimuth angle in both modalities.

Regularized Curve Fitting Improves T1 Bias in Cardiac T2 Mapping

Galen D Reed¹, Kenneth O Johnson¹, Michelle M Nystrom¹, Okai Addy¹, Reeve Ingle¹, Bob Hu¹, Juan Santos¹, and William Overall¹

¹HeartVista, Los Altos, CA, United States

Bias error is studied in T2-prepared single shot SSFP cardiac T2 mapping. Phantom experiments showed that although centric phase encode ordering reduces bias from T1 relaxation during single shot readouts, a residual bias of approximately 20% remains in the 1000 ms T1 regime. A regularized, three parameter exponential fitting model reduces this bias and generates T2 maps with low variance using 4 echo times.

Workflow Improvement with a Cardiac MRI Positioning Assist Function

Kensuke Shinoda¹, Shuhei Takemoto¹, and Shuhei Nitta²

¹MRI Systems Division, Toshiba Medical Systems Corporation, Tochigi, Japan, ²Corporate Research & Development Center, Toshiba Corporation

In this study, we evaluated how the Cardiac MRI positioning assist function can reduce the operation steps and times in CMRI. When using the assist function, the total number of the operation steps was reduced to about 25% for both the experts and the beginners. The operation time was also reduced to about 25%. The mean and SD of the elapsed time for the CMRI procedure performed by experts were reduced from 42m17s±10m53s to 32m46s±3m29s, and those for coronary angiography were reduced from 20m42s±8m5s to 15m22s±2m49s.

4D Flow MRI based aortic wall shear stress analysis using two different software tools and datasets from MRI scanners of two different appliance brands

Michael Peter Beldoch¹, Thekla Helene Oechtering¹, Victoria Schultz¹, Peter Hunold¹, Joerg Barkhausen¹, and Alex Frydrychowicz¹

¹Clinic for Radiology and Nuclear Medicine, University Hospital Schleswig-Holstein, Lübeck, Germany

Wall shear stress (WSS) is an increasingly used vessel wall parameter derived from 4D Flow-MRI data. There is no reference standard for evaluating WSS and different software approaches are available. However, their comparability is not known. Hence, it was the aim of this study to compare two available software tools (GTFlow and FlowTool). To achieve this goal, data from 21 healthy volunteers scanned on MRI scanners of different vendors were analyzed with respect to average and segmental WSS. Results showed good agreement between tools.

Computer 24

Evaluation of three-dimensional magnetic resonance imaging of autopsied human heart specimens for computational modeling of congenital heart diseases

Yoshiaki Morita¹, Wataru Ueki¹, Ryo Haraguchi², Takaaki Matsuyama³, Yoshiaki Watanabe¹, Tatsuya Nishii¹, Atsushi Kono¹, Naoaki Yamada¹, and Tetsuya Fukuda¹

¹Department of Radiology, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan, ²Division of Medical informatics, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan, ³Department of Pathology, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan

This study aimed to compare the visibility of a formalin-fixed heart using various 3D MRI sequences as well as to determine the optimal sequence for computational modeling of congenital heart diseases. Our results demonstrated that MPRAGE showed the best contrast with good image quality for imaging of the myocardium and the vascular structure when surrounded by normal saline in a plastic container. We believe that computational cardiac modeling of human autopsied heart specimens using MPRAGE plays a critical role in education and/or research.

FOCUS diffusion-weighted imaging for prostate cancer at high b-values: An analysis of image quality, diagnostic accuracy and observer agreement.

Tom Syer¹, Keith Godley², Donnie Cameron¹, and Paul Malcolm²

Parameter	FOCUS	Conventional DWI
SNR	0.85 ± 0.12	1.25 ± 0.15
CNR	0.75 ± 0.10	1.15 ± 0.14
ADC (mm ² /s)	0.85 ± 0.10	0.95 ± 0.12
Observer Agreement	0.85 ± 0.05	0.75 ± 0.08

¹Norwich Medical School, University of East Anglia, Norwich, United Kingdom, ²Radiology, Norfolk and Norwich University Hospital

To assess FOCUS diffusion-weighted imaging (DWI) for prostate cancer assessment, 30 consecutive biopsy-proven patients underwent both FOCUS and conventional DWI. Sensitivity and specificity was not significantly different between sequences but inter-observer agreement improved from moderate to substantial when using FOCUS. There was significantly lower SNR and CNR for FOCUS on b-value images, but similar CNR on ADC maps. Mean ADC values were significantly lower using FOCUS and both sequences showed excellent discrimination between malignant and benign prostate with no statistical difference. FOCUS DWI improves agreement between observers of varying experience while maintaining diagnostic accuracy despite lower SNR and CNR.

Target performance of MRI-ultrasound fusion guided prostate biopsy in a cohort of patients suspicious for prostate cancer

Matthias Gergely Zadory¹, Jean-Luc Fehr², Claudius Moeckel², Seife Hailemariam³, Johannes Maite Froehlich¹, and Michael Patak⁴

¹Pharmaceutical sciences institute, ETHZ, Zurich, Switzerland, ²Zentrum für Urologie, Hirslanden Klinik, Zurich, Switzerland, ³Institut für histologische und zytologische Diagnostik, Aarau, Switzerland, ⁴Radiologie, Hirslanden Klinik, Zurich, Switzerland

Conventional systematic core biopsies might fail to detect clinical significant prostate cancer. ARTEMIS MRI-ultrasound fusion guided prostate biopsy (ART-PBx) might overcome this issue by improving the targeting of suspicious lesions. In a retrospective clinical study including 194 patients (243 lesions) we determined a target performance of 56.3 % positive biopsies related to histopathology. The detection rate rises up to 71.4% for high score lesions (PIRADS 5) but did not show any correlation with lesion's size. This target methodology based on MRI achieves greater detection rate of clinical significant prostate cancer, improving the ability to appropriately counsel patients regarding therapy.

Computer 27

Role of DWI in guiding MRI-TRUS fusion biopsy in patients with prostate cancer: a prospective cohort study

Chandan J Das¹, Rohit Kaushal², Sanjay Sharma¹, Rajeev Kumar³, P N Dogra³, and S DattaGupta⁴

¹Radiology, All India Institute of Medical Sciences, New Delhi, India, ²Urology, All India Institute of Medical Sciences, New Delhi, India, ³Urology, All India Institute of Medical Sciences, New Delhi, India, ⁴Pathology, All India Institute of Medical Sciences, New Delhi, India, ⁵Pathology, All India Institute of Medical Sciences, New Delhi, India

Transrectal ultrasound (TRUS) guided 12 core biopsy of prostate has a sensitivity of 39-52%. We prospectively evaluated the role of DWI in guiding MRI-TRUS fusion biopsy. MRI was performed on a 3 Tesla system. PIRAD score was assigned and PIRAD 3-5 score were subjected to targeted fusion biopsy using the Artemis device along with standard 12 core biopsies. Targeted biopsy detected a higher number (93%) of clinically significant cancers and 71% cancers were upgraded to significant cancer on targeted biopsy. Fusion biopsies guided by DWI thus provide incremental information over standard TRUS biopsies in the diagnosis of significant prostate cancer.

Computer 28

MR-based machine learning analysis can help to predict pathological outcome of biopsy-proven Gleason score 3+3 prostate cancer
Chen-Jiang Wu¹, Yu-Dong Zhang¹, and Hai-Bin Shi¹

¹Department of Radiology, the First Affiliated Hospital with Nanjing Medical University, Nanjing, China, People's Republic of China

Machine learning-based analysis of multi-parametric was used to predict pathological outcome of biopsy-proven Gleason score 3+3 prostate cancer and proven to be better compared with single any MR or clinical parameter in predicting pathological outcome.

4780

Computer 29

Diffusion-Kurtosis imaging predicts tumor upgrading in biopsy-proven Gleason score = 6 prostate cancers
Chen-Jiang Wu¹, Yu-Dong Zhang¹, and Hai-Bin Shi¹

¹Department of Radiology, the First Affiliated Hospital with Nanjing Medical University, Nanjing, China, People's Republic of China

The study investigated the feasibility of Diffusion Kurtosis Imaging (DKI) in predicting surgical result upgrading of biopsy-proven Gleason Score (GS) = 6 prostate cancer. The predicting efficiency of clinical variables (tumor volume, PSA level) and MRI variables (ADC, Dapp, Kapp) were compared by ROC analysis. DKI was found feasible to predict surgical result upgrading of biopsy-proven GS = 6 prostate cancer and Dapp-minimum had the highest Az value.

4781

Computer 30

DWI of prostate cancer beyond ADC: correlation with histopathology

Stefanie Hectors¹, Sahar Semaan¹, Christopher Song¹, Ashutosh Tewari², George K Haines³, and Bachir Taouli¹

¹Translational and Molecular Imaging Institute, Icahn School of Medicine at Mount Sinai, New York, NY, United States, ²Department of Urology, Icahn School of Medicine at Mount Sinai, New York, NY, United States, ³Department of Pathology, Icahn School of Medicine at Mount Sinai, New York, NY, United States

In this study, we correlated advanced DWI [diffusion kurtosis imaging (DKI), stretched-exponential (SE) DWI and diffusion tensor imaging (DTI)] parameters with fractional tissue fractions of nuclei, cytoplasm, cells, stroma and lumen and the nuclear-cytoplasmic ratio in prostate cancer (PCa) lesions. We found that all assessed diffusion methods showed significant correlations with cytoplasmic, cellular and/or stromal tissue fractions. Specifically, DKI seems promising for characterization of PCa tissue composition, since multiple significant correlations between histology parameters and both ADC_{DKI} and kurtosis parameter K were observed.

Mixed performance of PIRADS v2: a validation study

James Walton¹, Sajal Pokharel¹, E. David Crawford², Kavita Garg¹, Kimberly E. Lind¹, Emma Murugaveri³, and Nayana U. Patel¹

¹Radiology, University of Colorado School of Medicine, Aurora, CO, United States, ²Urology, University of Colorado School of Medicine, Aurora, CO, United States, ³Lake Erie College of Osteopathic Medicine

The second version of the Prostate Imaging Reporting and Data System (PIRADSv2) is the new standard for interpreting prostate MRI. Validation studies have been performed of this scheme, but many have used targeted biopsies as the reference standard. Our validation study is unique in utilizing 3D trans-perineal mapping biopsy (3DTMB) as the reference standard. With a total of 41 MRI lesions, PI-RADSv2 score = 5 lesions had a PPV for cancer of 1.0. However, when all significant lesions (PI-RADSv2 score ≥ 3) were included, the PPV is 0.29, with equal PPV of PI-RADS 3 and 4 lesions.

Single Slice vs. Volumetric Analysis of Multiparametric Prostate MRI Metrics

Edward William Johnston¹, Clare Allen², Michela Antonelli³, Nikolaos Dikaios¹, Sebastien Ourselin³, and Shonit Punwani¹

¹Centre for Medical Imaging, University College London, London, United Kingdom, ²Radiology, University College London Hospitals, London, United Kingdom, ³Centre for Medical Image Computing, University College London, London, United Kingdom

Despite consensus guidelines advising volumetric analysis of tumours over single slice region-of-interest analysis, there is little data in the literature to support this recommendation. In this study we compare the reproducibility between each of these two methods in 20 patients with prostate cancer and also determine the intraobserver repeatability of each method. We show high levels of agreement and intraobserver repeatability in both of these methods. This study suggests that region-of-interest analysis is a perfectly acceptable analytical method and may have higher intraobserver repeatability than volumetric analysis, and could expedite the analysis of multiparametric prostate MRI datasets in clinical trials.

4784

Improving the Reproducibility of Quantitative Imaging Metrics for Multicentre Multiparametric Prostate MRI Trials

Edward William Johnston¹, Michela Antonelli², Nikolaos Dikaios¹, Sebastien Ourselin², David Atkinson¹, and Shonit Punwani¹

¹Centre for Medical Imaging, University College London, London, United Kingdom, ²Centre for Medical Image Computing, University College London, London, United Kingdom

Whilst multi-scanner studies provide the most robust evidence for quantitative imaging trials, they tend to be limited by poor reproducibility of scans performed on different scanners. In this study, 14 patients underwent paired multiparametric prostate MRI within 3 months of each other. We found that normalisation of T2 signal to the bladder improved the reproducibility of both peripheral zone and transition zone metrics considerably when compared with the current convention of using obturator internus. Whilst ADC also met sufficient levels of reproducibility, semiquantitative and quantitative DCE analysis and histographic features failed to do so.

Intratumoural heterogeneity (ITH) has been shown to predict overall survival in prostate cancer, and non-invasive biomarkers that can measure this genetic diversity would be welcome. In this study, we correlated imaging metrics derived from multiparametric prostate MRI with genomic heterogeneity indices and showed that low values of normalised T2 signal intensity within tumours are associated with a higher degree of mutational ITH. Our study shows the potential to use diagnostic imaging as a surrogate for genomic ITH in order to risk stratify patient for guiding management decisions.

[Preliminary application of magnetization transfer imaging and amide proton transfer imaging of prostate cancer at 3.0 tesla](#)

Xiangde Min¹, Zhaoyan Feng¹, Liang Wang¹, and Zhongping Zhang²

¹Tongji Medical College, Huazhong University of Science & Technology, Wuhan, People's Republic of China, ²GE Healthcare, Guangzhou, People's Republic of China

Magnetization transfer (MT) imaging and amide proton transfer (APT) imaging have reported many promising results. However, little is known about their usefulness for prostate cancer (PCa). In this study, MT-APT imaging were performed for 39 patients with pathological proven PCa. The feasibility of MT imaging and APT imaging for PCa detection was assessed, and their differential diagnostic values for PCa were compared. The results revealed that MTR(16.5 ppm) increased in cancerous tissues compared with normal PZs, and MT imaging outperformed APT imaging for PCa diagnosis. MT imaging showed promising role in the diagnosis of PCa.

[Prostate Cancer Diffusion Signal Analysis: Combination of Multiple Fit Parameters Improves Tissue Discrimination](#)

Stephan E. Maier^{1,2}, Thiele Kobus³, Andriy Fedorov¹, Fredrik Langkilde², Ruth Dunne¹, Robert V. Mulkern⁴, and Clare M. Tempany¹

¹Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ²Radiology, Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden, ³Department of Radiology and Nuclear Medicine, Radboud University Medical Center, Netherlands, ⁴Radiology, Children's Hospital, Harvard Medical School, Boston, MA, United States

Diffusion signals over an extended b-factor range 0-3500 s/mm² were measured with an endorectal coil at 3 Tesla in 56 prostate cancer patients. For each pixel, signal decay fits were computed assuming biexponential, kurtosis, stretched exponential and gamma distribution diffusion signal models. The potential of individual parameters and linear parameter combinations to differentiate normal from cancerous tissue was evaluated with ROC analysis. For the kurtosis and stretched exponential models, single parameters yield the highest AUCs, whereas for the biexponential and gamma distribution models, only combinations of parameters produce the comparably high AUCs.

Ex vivo MRI evaluation of prostate cancer: localization and margin status prediction of prostate cancer in fresh radical prostatectomy specimens

Jan Heidkamp¹, Martijn Hoogenboom¹, Iringo Kovacs², Andor Veltien¹, Arie Maat², Michiel Sedelaar³, Christina Hulsbergen-van de Kaa², and Jurgen Fütterer¹

¹Radiology and Nuclear Medicine, Radboud university medical center, Nijmegen, Netherlands, ²Pathology, Radboud university medical center, Nijmegen, Netherlands, ³Urology, Radboud university medical center, Nijmegen, Netherlands

This study investigated the ability of high field ex vivo MRI to localize prostate cancer (PCa) and to predict the margin status in fresh radical prostatectomy (RP) specimens using histology as gold standard. In twelve specimens, ex vivo MRI localized 17 (47%) of 36 PCa lesions confirmed by histological examination. Ex vivo MRI identified none of the 4 histological positive surgical margins (sensitivity 0%) and 9 of the 13 negative margins (specificity 69%). Our results indicate accurate localization of PCa in fresh RP specimens by ex vivo MRI, yet the technique did not perform well in predicting the margin status.

4792

Computer 41

Clinical Evaluation of a Simple Approach for Improving Shear Wave Illumination in Magnetic Resonance Elastography of the Prostate

Jin Wang¹, Tianhui Zhang¹, Kevin J. Glaser², Jingbiao Chen¹, Jun Chen², Phillip J. Rossman², Bingjun He¹, Arvin Arani², Ziyang Yin², Zhuang Kang¹, Qungang Shan¹, Jun Pang³, and Richard L. Ehman²

¹Department of Radiology, the Third Affiliated Hospital, Sun Yat-sen University (SYSU), Guangzhou, People's Republic of China, ²Department of Radiology, Mayo Clinic, Rochester, United States, ³Department of Urology, the Third Affiliated Hospital, Sun Yat-sen University (SYSU), Guangzhou, People's Republic of China

Conventional prostate magnetic resonance elastography (MRE) is performed using an external driver to transmit shear waves into the prostate. It is a challenge to produce shear waves in the prostate with adequate amplitude at a suitably high frequency because the prostate is a deep-seated organ. We evaluated the hypothesis that the placement of a urinary catheter would improve the shear wave illumination of the prostate when waves are emitted from an external driver. Our results in 30 BPH patients show that the commercially available liver MRE driver used in combination with a catheter can improve MRE image quality at higher frequencies.

4793

Computer 42

Linking a multi-compartment T2 model to diffusion microstructure in prostate cancer

William Devine¹, Edward Johnston¹, Elisenda Bonet-Carne², Shonit Punwani¹, Daniel Alexander², and David Atkinson¹

¹Centre for Medical Imaging, University College London, London, United Kingdom, ²Centre for Medical Image Computing, University College London, London, United Kingdom

This work develops a multi-compartment T2 model for prostate imaging. We investigate whether this model can provide information about differences in tissue microstructure, such as those between normal prostate tissue and tumour, by comparing it to the VERDICT diffusion model⁶. The high correlations found between a number of the parameters suggest that the proposed model is capable of detecting some microstructural differences. In the future this method may be able to provide different and complementary microstructural information to current diffusion models.

4794

Computer 43

Magnetic Resonance Elastography of the Prostate: Impact of Driver Size on Image Quality

Tianhui Zhang¹, Jin Wang¹, Kevin J. Glaser², Phillip J. Rossman², Jun Chen², Bingjun He¹, Jun Pang³, Ziyang Yin², Zhuang Kang¹, Qungang Shan¹, Jingbiao Chen¹, Arvin Arani², and Richard L. Ehman²

¹Department of Radiology, the Third Affiliated Hospital, Sun Yat-sen University (SYSU), Guangzhou, People's Republic of China, ²Department of Radiology, Mayo Clinic, Rochester, United States, ³Department of Urology, the Third Affiliated Hospital, Sun Yat-sen University (SYSU), Guangzhou, People's Republic of China

Conventional prostate MRE uses an external driver located on the surface of the body to transmit shear waves into the prostate. However, the conventional large-diameter driver produces poorer image quality at higher frequencies. In this study we compared the performance of a large- and small-diameter Pelvic Wall driver at multiple frequencies using 2D and 3D MRE. Our results show that the smaller Pelvic Wall driver performs better than the larger driver in terms of image quality and success rate.

TRUS Biopsy Has a Lower Cancer Detection Rate in Large Prostate Volumes: Can In-Bore MRI-Guided Biopsy Do Better?

Kareem K Elfatairy¹, Christopher P Filson², Adeboye O Osunkoya³, Rachel G Geller³, and Sherif G Nour¹

¹Radiology, Emory University-School of Medicine, Atlanta, GA, United States, ²Urology, Emory University-School of Medicine, GA, United States, ³Pathology, Emory University-School of Medicine, Atlanta, GA, United States

TRUS biopsy known to have low cancer detection rates in patients with large prostate volumes. With the proved advantages of MRI guided biopsy (MRGB), it may offer a better alternative to those patients. We compared between cancer detection rates of TRUS biopsy and MRGB in 49 patients as related to their prostate volumes. MRGB showed better detection of clinically significant cancers in prostate volumes between 30-59 mL. Adopting MRGB in patients with gland volumes ≥ 30 mL may save patients the need for repeated TRUS biopsies, provide better disease risk stratification, and reduce the healthcare costs associated with unnecessary biopsies.

The dispersion imaging has shown great promise in prostate DCE-MRI, but there still exist practical limitations due to the complex model fitting. We describe a modified dispersion model to overcome these limitations by adapting a simple dispersion factor into the existing population-averaged arterial input function. We use the regions of interest, derived from the histological analysis, to evaluate both the quality of the model fitting and the ability of DCE-MRI parameters to delineate between cancerous and normal prostate tissues using 25 prostate patient cases available with the whole-mount histopathology.

A Transverse External RF Surface Coil for Prostate MR Imaging at 3T

Keith Hulsey¹, Alexander Ivanishev¹, Ivan Dimitrov^{2,3}, and Robert E. Lenkinski^{1,2}

¹Radiology, UT Southwestern Medical Center, Dallas, TX, United States, ²Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, TX, United States, ³Philips Medical Systems, Cleveland, OH, United States

MRI is playing an increasingly important role in the work up of prostate cancer. This increased demand for prostate imaging has caused a debate in the field regarding the necessity of an endo-rectal coil for these studies. While the endo-rectal coil has distinct advantages it also has some drawbacks in both work-flow and cost. Current external coils do not provide images at comparable SNR to endo-rectal coil images (at the same field strength). Here we describe our initial experience with a transverse external RF coil designed to be placed on the perineum for high quality images.

Multiparametric MRI is becoming a crucial imaging for prostate cancers. A novel advanced, diffusion-based technique, restriction spectrum imaging (RSI) has been applied for prostate cancer imaging recently. In this work we will investigate the RSI performance in prostate cancer evaluation verified by post-surgery whole mount histopathology slides.

We propose a new multi-compartment model for the tissue signal in MRI and apply this to images of liver and placenta. Motivated by different flow characteristics in these organs, a three compartment model comprising fast and slowly circulating fluid pools and a tissue pool is fitted to overlapping multi-echo T2 relaxometry and an intra-voxel incoherent motion diffusion acquisition with low b-values. We compare and contrast parametric maps for regions of interest in liver and placenta.

[Perfusion MRI of the Placenta: Preliminary Results using ASL FAIR and Ferumoxytol DCE MRI in the Rhesus Macaque](#)

Kai D. Ludwig¹, Sean B. Fain^{1,2,3}, Sydney Nguyen⁴, Thaddeus G. Golos^{4,5}, Scott B. Reeder^{1,2,3,6,7}, Ian M. Bird⁵, Oliver E. Wieben^{1,2}, Dinesh M. Shah⁵, and Kevin M. Johnson¹

¹Medical Physics, University of Wisconsin - Madison, Madison, WI, United States, ²Radiology, University of Wisconsin - Madison, Madison, WI, United States, ³Biomedical Engineering, University of Wisconsin - Madison, Madison, WI, United States, ⁴Comparative Biosciences, University of Wisconsin - Madison, Madison, WI, United States, ⁵Obstetrics and Gynecology, University of Wisconsin - Madison, Madison, WI, United States, ⁶Medicine, University of Wisconsin - Madison, Madison, WI, United States, ⁷Emergency Medicine, University of Wisconsin - Madison, Madison, WI, United States

Non-contrast enhanced methods are needed to quantify placental perfusion to detect and monitor pathophysiological changes during pregnancy. We evaluate the potential of an endogenous perfusion labeling perfusion technique, Arterial Spin Labeled Flow-sensitive Alternating Inversion Recovery (ASL FAIR), and compare with ferumoxytol dynamic contrast enhanced (DCE) MRI. Three pregnant rhesus macaque were imaged with both FAIR and ferumoxytol DCE. Localized regions of ASL perfusion were observed that coincided with regions of early contrast enhancement seen in DCE. Ferumoxytol DCE measured perfusion with extended transit times across the placenta beyond those typically used for ASL labeling.

Proper placental function is essential for normal fetal development. MRI can easily assess the growth and development of the placenta throughout gestation due to its capabilities in functional imaging. However, uterine contractions, and fetal and maternal motion can lead to inaccuracies in the quantitative assessments. In this we assessed the impact of extraneous motion on placental imaging by using a 3D multi-echo golden angle radial sequence to generated dynamic images of the placenta.

[Differentiating metastatic from nonmetastatic lymph nodes by using monoexponential, biexponential, and stretched exponential diffusion-weighted imaging in cervical cancer patients](#)

Qingxia Wu¹, Dandan Zheng², Ligang Shi³, Mingbo Liu⁴, Meiyun Wang¹, and Dapeng Shi¹

¹Radiological Department, Henan Provincial People's Hospital (Zhengzhou University People's Hospital), Zhengzhou, People's Republic of China, ²MR Research China, GE Healthcare, Beijing, People's Republic of China, ³Pathological Department, Henan Provincial People's Hospital (Zhengzhou University People's Hospital), Zhengzhou, People's Republic of China, ⁴Radiotherapeutical Department, Henan Provincial People's Hospital (Zhengzhou University People's Hospital), Zhengzhou, People's Republic of China

The aim of our study was to judge whether diffusion parameters derived from different models of multi-b value DWI could be used to discriminate metastatic from nonmetastatic pelvic lymph node (LN) status in patients with cervical cancer. A statistical significant difference in the mean D, f and α values between metastatic and nonmetastatic LNs, with metastatic LNs presenting with higher D values, lower f values and higher α values than nonmetastatic ones. This study revealed that metastatic LNs had their respective diffusion parameters compared with nonmetastatic LNs.

[Comparison of 18F-FDG PET/MRI and MRI alone for pretherapeutic tumor staging of patients with primary cancer of the uterine cervix.](#)

Johannes Grueneisen¹, Lino Morris Sawicki, Axel Wetter, Julian Kirchner, Michael Forsting, Verena Ruhlmann, and Lale Umutlu

¹Diagnostic and Interventional Radiology, University Hospital Essen, Essen, Germany

This study demonstrates a successful attempt to utilize and evaluate the diagnostic potential of integrated PET/MRI for staging patients with primary cervical cancer. According to the results, 18F-FDG PET data do not seem to provide useful additional information to MRI for the determination of the local extent of the primary tumors. However, the present results show a better performance of simultaneously acquired 18F-FDG PET and MR datasets for the detection of nodal and distant metastases if compared to MRI alone. Therefore, integrated PET/MR imaging may provide valuable information for treatment planning and to predict prognosis.

Non-invasive placental perfusion imaging in pregnancies complicated by fetal heart disease using velocity-selective arterial spin labeling
Zungho Zun^{1,2,3}, Greg Zaharchuk⁴, Nickie Niforatos-Andescavage^{1,2}, Samantha Bauer¹, Mary T Donofrio^{2,3,5}, and Catherine Limperopoulos^{1,2,3}

¹Division of Diagnostic Imaging and Radiology, Children's National Medical Center, Washington, DC, United States, ²Division of Fetal and Transitional Medicine, Children's National Medical Center, Washington, DC, United States, ³Departments of Radiology and Pediatrics, George Washington University, Washington, DC, United States, ⁴Department of Radiology, Stanford University, Stanford, CA, United States, ⁵Division of Cardiology, Children's National Medical Center, Washington, DC, United States

Recent data have reported that placental dysfunction may be present in the setting of complex fetal congenital heart disease (CHD). We performed placental perfusion imaging using velocity-selective arterial spin labeling in pregnancies complicated by fetal CHD and healthy pregnancies. We demonstrated that global placental perfusion and regional variation of perfusion were significantly correlated with GA in pregnancies complicated by fetal CHD, but not in healthy controls. Our findings suggest that placental ASL may have the potential to serve as an early biomarker of placental dysfunction in fetal CHD.

Pelvic Floor Structural Alterations of Primipara with Stress Urinary Incontinence After Vaginal Delivery : A MRI Study

yujiao zhao¹, zhizheng zhuo², and wen shen¹

¹Department of Radiology, Tianjin First Center Hospital, Tianjin, People's Republic of China, ²Philips Healthcare, Beijing, China, Beijing, People's Republic of China

Vaginal childbirth women have an increasing incidence of stress urinary incontinence(SUI). There are few studies on pathogenesis of SUI and the relationship between the SUI and pelvic floor structure changes. In this study, static and dynamic MRI imaging are performed to describe and assess pelvic floor structure changes in patients with stress urinary incontinence. The results showed that pelvic floor structures changed significantly in the primipara suffering from SUI after vaginal delivery, which suggest a series of pathological state.

4809

Placental vascular dysfunction is a major cause of pregnancy complications, such as intrauterine growth restriction (IUGR). However, current knowledge on human placental vascular architecture is limited. In this study, for the first time, we characterized the structure of the placental vascular system ex-vivo, using MRI. Fifteen normal placentas and one with IUGR were studied using a novel method, and the vascular structure was analyzed with an automatic algorithm. Results provided information regarding: cord insertion location; branching pattern; branching generation; and daughter to mother diameters of normal placentas. Preliminary results from one IUGR placenta suggest significant differences from normal placentas.

¹Medical Physics, University of Wisconsin - Madison, Madison, WI, United States, ²Comparative Biosciences, University of Wisconsin - Madison, Madison, WI, United States, ³Radiology, University of Wisconsin - Madison, Madison, WI, United States, ⁴Biomedical Engineering, University of Wisconsin - Madison, Madison, WI, United States, ⁵Medicine, University of Wisconsin - Madison, Madison, WI, United States, ⁶Emergency Medicine, University of Wisconsin - Madison, Madison, WI, United States, ⁷Obstetrics and Gynecology, University of Wisconsin - Madison, Madison, WI, United States, ⁸Wisconsin National Primate Research Center, University of Wisconsin - Madison, Madison, WI, United States

Both maternal and fetal complications arise from poor vascular adaptation to pregnancy. Assessing utero-placental vessels with contrast-enhanced MR Angiography may be valuable, but Gadolinium based contrast agents commonly used for MR angiography are contraindicated during pregnancy. In this work, we tested the feasibility of ultrashort echo time contrast-enhanced angiography with Ferumoxytol in a small cohort of pregnant rhesus macaques. Ferumoxytol allowed for detailed visualization of utero-placental vessels without detectable uptake in fetal tissues.

Myometrial invasion in endometrial cancer: Comparison of reduced field-of-view diffusion-weighted imaging and dynamic contrast-enhanced magnetic resonance imaging

Mayumi Takeuchi¹, Kenji Matsuzaki², and Masafumi Harada¹

¹Department of Radiology, Tokushima University, Tokushima, Japan, ²Department of Radiological Technology, Tokushima Bunri University, Sanuki-city, Japan

The depth of myometrial invasion was evaluated in 25 patients with surgically proven endometrial cancer by T2WI, reduced field-of-view DWI (rFOV-DWI) and 3D dynamic contrast-enhanced MRI (DCE-MRI). The depth of myometrial invasion (stage S: <50% vs stage D: ≥50%) on MRI was correlated with surgical pathology results. The staging accuracy was 68% for T2WI, 92% for DCE-MRI, and 96% for rFOV-DWI. Combination of rFOV-DWI reading together with T2WI improved the assessment of myometrial invasion with a diagnostic accuracy of up to 100%. Especially, rFOV-DWI has an advantage in assessing the depth of myometrial invasion in cases with coexisting adenomyosis.

4814

Computer 63

Red degeneration of uterine leiomyoma: Clinical utility of susceptibility-weighted MR imaging

Mayumi Takeuchi¹, Kenji Matsuzaki², and Masafumi Harada¹

¹Department of Radiology, Tokushima University, Tokushima, Japan, ²Department of Radiological Technology, Tokushima Bunri University, Sanuki-city, Japan

Red degeneration of uterine leiomyoma (RDL) is hemorrhagic infarction caused by peripheral venous thrombosis. Peripheral high intensity rim on T1WI due to methemoglobin of blood products confined to thrombosed vessels is characteristic, however, it may not be observed at acute phase. We evaluated MR images including SWI of 17 RDL and 12 usual leiomyomas (UL). High intensity rim on T1WI, low intensity rim on T2WI and on SWI were observed in 47%, 47%, and 100% of RDL, whereas 0%, 8%, and 0% of UL, respectively. SWI may be helpful for the diagnosis of RDL in distinguishing from UL or sarcomas.

[MR non-Gaussian diffusion model of female cervix: a diffusion kurtosis imaging study](#)
Wenhui Guo¹, Kuang Fu¹, and Lizhi Xie²

¹Department of MR, The Second Affiliated Hospital of Harbin Medical University, Harbin, People's Republic of China, ²GE Healthcare, MR Research China, Beijing, People's Republic of China

To assess the fitted parameters of DKI in female cervix and to investigate their potential in distinguishing tumors from diverse healthy tissues. The presence of rich collagen and fibers in healthy cervix helps to differentiate itself from the heterogeneous and cell-rich malignancies. It is concluded that DKI can be performed as a feasible technique to depict the real phenomenon of non-Gaussian water diffusion behavior in female cervix.

4817

Computer 66

[Histogram analysis of intravoxel incoherent motion parameters in assessing tumour diffusion and perfusion heterogeneity in cervical cancer before and after chemoradiotherapy](#)

Jose Angelo Udal Perucho¹, Elaine Yuen Phin Lee¹, Wing Chi Lawrence Chan², Nanjie Gong³, and Queenie Chan⁴

¹Department of Diagnostic Radiology, The University of Hong Kong, Hong Kong, Hong Kong, ²Department of Health Technology and Informatics, The Hong Kong Polytechnic University, Hong Kong, ³University of California, Berkeley, CA, United States, ⁴Philips Healthcare, Hong Kong, Hong Kong

Histogram analysis of intravoxel incoherent motion (IVIM) diffusion-weighted MRI (DWI) could be a promising quantitative approach in assessing tumour heterogeneity. We retrospectively studied twenty-five patients with cervical cancer who had paired IVIM MRI examinations before and at week-4 of chemoradiotherapy treatment (CRT). We observed histogram skewness and kurtosis significantly decreased while mean and all percentiles significantly increased in apparent diffusion coefficient (ADC), true diffusion coefficient (D) and perfusion fraction (f) following treatment. Furthermore, these significant differences were not correlated with a change in primary tumour volume (PTV) following treatment.

4818

Pseudo-fat in the fetal liver with two-point Dixon water-fat separationStephanie A Giza¹, Barbra de Vrijer^{2,3}, and Charles A McKenzie^{1,3}

¹Medical Biophysics, The University of Western Ontario, London, ON, Canada, ²Obstetrics and Gynaecology, The University of Western Ontario, London, ON, Canada, ³Division of Maternal, Fetal and Newborn Health, Children's Health Research Institute, London, ON, Canada

2-point Dixon water-fat imaging is a widely available sequence that can be used to generate fat images. Increased fat was seen in the livers of a 35+4 week anencephalic fetus and a 37 week normal fetus on 2-point Dixon images, but not with IDEAL water-fat imaging. When applied to the fetus late in gestation, caution should be taken as a shortened fetal liver T2* may appear as false liver fat. IDEAL water-fat imaging corrects for changes in T2* and is a more appropriate sequence for fetal water-fat separated imaging in the third trimester.

4822

Application of Texture Analysis to Apparent Diffusion Coefficient Images of the Normal Human PlacentaQuyenn N. Do¹, Matthew A. Lewis¹, Ananth J. Madhuranthakam^{1,2}, Yin Xi^{1,3}, April Bailey^{1,4}, and Diane Twickler^{1,4}

¹Radiology, University of Texas Southwestern Medical Center, Dallas, TX, United States, ²Advanced Imaging Research Center, University of Texas Southwestern Medical Center, Dallas, TX, United States, ³Department of Clinical Science, University of Texas Southwestern Medical Center, Dallas, TX, United States, ⁴Obstetrics & Gynecology, University of Texas Southwestern Medical Center, Dallas, TX, United States

The human placenta is a complex structure with unique capabilities. It has a 40-week average life span, during which it facilitates the exchange between the maternal and fetal cardiovascular systems. There is little known about the development and maturation of the placenta throughout the gestational period during normal pregnancy. It is however recognized that the placenta appears more heterogeneous on various imaging modalities as the pregnancy progresses. In this work, we propose to characterize the placenta heterogeneity as a function of gestational age through the application of grey-scale texture analysis to ADC maps using a large retrospective MRI database.

Comparing the invasive depth of esophageal carcinoma in 3.0 T ex vivo T2-mapping MR imaging with histopathological findingsDandan Zheng¹, Yi Wei², and Shaocheng Zhu²

¹MR Research China, GE Healthcare, Beijing, People's Republic of China, ²Radiology, Zhengzhou University People's Hospital, Zhengzhou, People's Republic of China

Esophageal carcinoma is the eighth most common cancer worldwide with a rising incidence. It has been demonstrated that the normal esophageal wall can be depicted as eight layers in T2 weighted MRI, however only qualitative assessment has been made so far. In this work, an ex vivo experiment was conducted on 3.0T clinical scanner to prospectively establish the quantitative T2 value as a means of depicting the normal esophageal wall by T2-mapping and evaluate the depth of the carcinoma invasion using histopathological as a reference.

- 4825 **Computer 74** [Whole body functional and anatomical MRI: Accuracy in staging of Childhood and Adolescent Hodgkin's Lymphoma compared to conventional multimodality imaging](#)

 Arash Latifoltojar¹, Shonit Punwani¹, Paul Humphries¹, Leon Menezes², Deena Neriman², Stephen Daw², Ananth Shankar², Bilyana Popova¹, Paul Smith¹, Ka Man Condne¹, Andre Lopes¹, and Stuart Taylor¹
¹University College London, London, United Kingdom, ²University College London Hospital, London, United Kingdom
 Current gold standard imaging for assessment of paediatric Hodgkin's lymphoma is PET-CT. Anatomical and functional whole-body MRI (WB-MRI) provides an alternative/adjunct radiation free imaging technique.
 The aim of this prospective single centre study is to investigate the diagnostic accuracy of WB-MRI against reference standard imaging for staging of paediatric Hodgkin's lymphoma.
-
- 4826 **Computer 75** [A Novel Retrospective Sorting Strategy Utilizing both Respiratory Profile and Internal Surrogate Position for Generating Free-Breathing Abdominal 4D-MRI](#)

 Yihang Zhou¹, Oi Lei Wong¹, Jing Yuan¹, George Chiu², Kin Yin Cheung¹, and Siu Ki Yu¹
¹Medical Physics and Research Department, Hong Kong Sanatorium & Hospital, Happy Valley, Hong Kong, ²Department of Radiotherapy, Hong Kong Sanatorium & Hospital, Happy Valley, Hong Kong
 Four-dimensional (4D) image are widely used to capture the respiration-induced motion of the abdominal organs in free-breathing radiotherapy. However, due to the breathing variability, appropriate assignment of images to each phase is critical in revealing the motion of anatomy structures. In this study, we proposed a novel approach to develop high-quality retrospective 4D-MRI. Instead of sorting images only based on their respiratory phases, the proposed strategy sorted the images using both the respiratory phases and the internal surrogate positions. The proposed strategy was tested using in-vivo human abdominal images.
-
- 4827 **Computer 76** [Complex Chemical Shift-Encoded MRI to Estimate Fat in Livers with Elevated Iron Content](#)

- 4828 **Computer 77** [Amplitude-probability sorting for single-pass, retrospective 4D-MRI using 2D bSSFP MRI with interleaved cylindrical navigators](#)

 Erik Tryggestad¹, Ersin Bayram², Yanle Hu³, Daniel Litwiller⁴, Dan Rettmann², Matthew Walb¹, Darin White⁵, and Kieran McGee⁵
¹Radiation Oncology, Mayo Clinic, Rochester, MN, United States, ²GE Healthcare, Waukesha, WI, United States, ³Radiation Oncology, Mayo Clinic, Phoenix, AZ, United States, ⁴GE Healthcare, New York, NY, United States, ⁵Radiology, Mayo Clinic, Rochester, MN, United States
 With MRI being increasingly incorporated in the radiotherapy workflow, the multidisciplinary community has a strong interest in developing "4D-MRI" techniques for both offline (tumor motion characterization for treatment planning) and online (tumor motion tracking) applications. In a cohort of 10 volunteers, the present study applied 2D (coronal) bSSFP with interleaved cylindrical navigators monitoring the liver dome to retrospectively derive 4D-MRI comparing two sorting methods, namely phase and amplitude-probability. Amplitude-probability binning was shown, both qualitatively and quantitatively, to reduce "volume inconsistencies" caused by variable breathing.
-
- 4829 **Computer 78** [3D MSVAT-SPACE-STIR or 2D SEMAC-STIR for high resolution dental MRI?](#)

 Tim Hilgenfeld¹, Marcel Prager², Alexander Heil², Daniel Gareis³, Mathias Nittka⁴, David Grodzki⁴, Martin Bendszus², and Sabine Heiland²
¹Heidelberg University, Heidelberg, Germany, ²Heidelberg University, ³NORAS MRI products GmbH, ⁴Siemens Healthcare GmbH
 Dental MRI is a new and promising diagnostic tool. Unfortunately, in presence of implants image quality is impaired by failure of fat suppression and susceptibility artifacts. Here, we for the first time systematically evaluated fat saturated MR sequences for artifact reduction for dental MRI. Smallest artifact volume was noted for SEMAC-STIR and TSE-STIR sequences. But, higher and isotropic resolution was only achieved with MSVAT-SPACE-STIR sequence. No artifact reduction was measured for SEMAC-STIR compared to standard TSE-STIR. In contrast, MSVAT-SPACE-STIR reduced artifacts up to 70% compared to standard SPACE-STIR. Since imaging of dental structures benefit from isotropic high resolution MSVAT-SPACE-STIR is advantageous.

- 4830 **Computer 79** [SAR-Constrained kT-Points Pulse Design Applied to B1 Inhomogeneity Mitigation in the Human Abdomen at 3T](#)

 Raphaël Tomi-Tricot¹, Vincent Gras¹, Franck Mauconduit², Nicolas Boulant¹, Pierre Zerbib³, Alain Rahmouni³, Alexandre Vignaud¹, Alain Luciani³, and Alexis Amadon¹
¹CEA-DRF-I2BM-NeuroSpin-UNIRS, Gif-sur-Yvette, France, ²Siemens Healthineers France, Saint-Denis, France, ³Department of Radiology, AP-HP, CHU Henri Mondor, Créteil, France

High field MRI systems offer better performance in terms of signal-to-noise ratio but are burdened with dielectric resonance artefacts inducing zones of weak excitation with major consequences on Signal and Contrast to Noise Ratios. In this work, the interest of subject-tailored k_T -points pulse design with joint SAR control over current patient-specific RF-shimming technique is investigated, in the context of human liver imaging at 3T. T1w acquisitions are performed in-vivo to compare quadrature, tailored RF-shimming, and k_T -points pulses. The interest of k_T -points is clearly demonstrated in terms of signal, contrast and diagnostic power.

Compressed Sensing Black Blood SPACE for Abdominal Aortic Aneurysmal Vessel Wall Imaging

Sinyeob Ahn¹, Chengcheng Zhu², Esther Raithe³, Christoph Forman³, Gerhard Laub¹, and David Saloner⁴

¹Siemens Healthcare, San Francisco, CA, United States, ²Radiology and Biomedical Imaging, UCSF, San Francisco, CA, United States, ³Siemens Healthcare, Erlangen, Germany, ⁴UCSF, San Francisco, CA, United States

Abdominal aortic vessel wall imaging has been interested and used for studying pathological vasculature. In this study, compressed sensing (CS) 3D SPACE DANTE technique is proposed for imaging abdominal aortic aneurysm (AAA) vessel wall to accelerate imaging acquisition. Its scan/reconstruction parameters were optimized on normal volunteers then, used for patient scan. DANTE provided sufficiently dark blood signal at a large vessel like the aorta, which is essential to delineate the vessel wall. CS SPACE DANTE provided comparable image quality and vessel wall-lumen signal contrast as compared to non-accelerated SPACE DANTE technique.

Quantitative comparison of time-SLIP and Triple Inversion Recovery (TIR) non-contrast enhanced MRI for renal angiography

Suzanne Franklin¹, Torben Schneider², Marcelo E Andia³, Markus Henningsson⁴, and Rene M Botnar⁴

¹Eindhoven University of Technology, Eindhoven, Netherlands, ²Philips Healthcare, Guildford, United Kingdom, ³Pontificia Universidad Católica de Chile, Escuela de Ingeniería, Santiago, Chile, ⁴King's College London, Division of Imaging Sciences, and Biomedical Engineering, St. Thomas' Hospital, London, United Kingdom

Renal artery stenosis (RAS) has been associated with hypertension, chronic kidney disease and an increased risk of vascular events. This study quantitatively compares two non-contrast enhanced magnetic resonance angiography (NC-MRA) techniques for renal angiography, based on SNR, CNR, vessel sharpness and number of renal branches. TIR has shown promising results in suppressing background signal and provided overall better image quality than outflow time-SLIP. TIR has the advantage over time-SLIP that tissues can be nulled over a wide range of T1 -values. To further shorten scan time the TIR technique could be combined with more advanced image based motion correction techniques.

Comparison of diffusion imaging microstructure models of the human placenta at 3T

Paddy J. Slator¹, Jana Hutter^{2,3}, Laura McCabe², Ana Dos Santos Gomes², Anthony N. Price^{2,3}, Mary A. Rutherford², Joseph V. Hajnal^{2,3}, and Daniel C. Alexander¹

¹Centre for Medical Image Computing, Department of Computer Science, University College London, London, United Kingdom, ²Centre for the Developing Brain, King's College London, London, United Kingdom, ³Biomedical Engineering Department, Division of Imaging Sciences, King's College London, London, United Kingdom

Developmental abnormalities in placental vascular formation are associated with major complications of pregnancy, such as fetal growth restriction and early onset pre-eclampsia. Multi-shell diffusion MRI at 3T has been shown to be capable of capturing fine microstructural information in a wide variety of organs and disease states, and could prove valuable for studying the human placenta in-vivo. We develop a rich scanning protocol, and use the data to investigate the complexity of models supported by the placental diffusion MRI signal. We demonstrate the feasibility of using this non-invasive approach to quantify microstructure in the human placenta and surrounding tissue.

Quantitative Assessment of Markers of Oxidative Stress in Mice Model of Renal Artery Stenosis

Behzad Ebrahimi^{1,2}, Alvin Ihsani², Arkadiusz Sitek², Slobodan I Macura³, and Lilach O Lerman¹

¹Nephrology, Mayo Clinic, Rochester, MN, United States, ²Radiology, Harvard/MGH, Boston, MA, United States, ³Biochemistry and Molecular Biology, Mayo Clinic

Inability of cells to detoxify reactive oxidative species (ROS) is responsible for numerous degenerative pathological conditions. Currently there is no clinical method to assess reduction-oxidation (redox) state in vivo. In this study, using a cyclic nitroxide T₁ MR probe with unique characteristics, we propose a two-tissue compartment model which provides quantitative information of markers of oxidative stress. Results demonstrated the feasibility of redox status assessment in vitro and in vivo in the stenotic mouse kidney. In the stenotic kidney, our method indicated increased renal ROS production, accompanied by preserved ability to detoxify ROS compared to the contralateral kidney.

Quantitative BOLD MRI and T1 Mapping in Acute Kidney Injury Patients: A preliminary study

Yingjie Mei^{1,2}, Xiang Xiao³, Zihan Lei⁴, Jie Feng³, Yuankui Wu³, Ruiying Chen³, Qiangqiang Gang³, Min Liang⁴, Yikai Xu³, and Yanqiu Feng¹

¹School of Biomedical Engineering, Guangdong Provincial Key Laboratory of Medical Image Processing, Southern Medical University, Guangzhou, People's Republic of China, ²Philips Healthcare, Guangzhou, People's Republic of China, ³Medical Imaging Center, Nanfang Hospital of Southern Medical University, Guangzhou, People's Republic of China, ⁴Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, People's Republic of China

Hypoperfusion and hypoxia are thought to be important factors in the pathogenesis of AKI and in the progression from AKI to chronic kidney disease. Previous studies have demonstrated the correlation between MR relaxation time (T₁ and T₂^{*}) and tissue oxygenation. The result of this preliminary study suggests BOLD and T₁ mapping are potential to diagnose AKI at early stage and predict the progression of AKI non-invasively.

- 4836 **Computer 85** [Fast, Motion-Robust T1-weighted Body Imaging with Single-Shot Fast Spin Echo via Centric Partial Fourier Encoding and Variable Refocusing Flip Angle](#)

¹Global MR Applications & Workflow, GE Healthcare, New York, NY, United States, ²Global MR Applications & Workflow, GE Healthcare, Menlo Park, CA, United States, ³Global MR Applications & Workflow, GE Healthcare, Houston, TX, United States
 Here we present a single-shot fast spin echo sequence optimized for fast, motion-robust T1-weighted body imaging through the use of inversion recovery preparation, and the introduction of variable refocusing flip angle configured for centric, partial Fourier encoding.
-
- 4837 **Computer 86** [Automated scan prescription for an oblique plane through the aortic arch for bolus tracking in DCE-MRI](#)

 Takao Goto¹, Miki Araki¹, and Kenji Asano¹
¹MR Engineering, GE Healthcare, Hino-shi, Japan
 Accurate placement of a 2D plane across the aorta arch while examining scout images is a complex task that makes the operator's workflow difficult when bolus tracking in DCE-MRI. We present a novel method for automated scan prescription for an oblique plane delineating the entire aortic arch used to monitor bolus arrival. The oblique plane was prescribed automatically by selecting the optimal oblique angle using regression forests. A dataset with 31 volunteers was tested, and all cases depicted the cross section of the aortic arch clearly. This automation will assist the operator and decrease the total examination time.

- 4838 **Computer 87** [The direct and indirect findings of pulmonary embolism found on contrast enhanced pulmonary Magnetic Resonance Angiography exams: A pictorial essay approach for the imager based on the real world findings found in over 600 patients](#)

 Mark Schiebler¹, Donald Benson¹, Christopher Francois¹, and Scott Nagle¹
¹Radiology, UW Madison School of Medicine and Public Health, Madison, WI, United States
 The use of contrast enhanced pulmonary magnetic resonance angiography (CE-MRA) is being used as a primary modality for the diagnosis of pulmonary embolism (PE) at our institution. We have found both direct and indirect findings of PE on CE-MRA images. It is of critical importance to have a thorough understanding of the pitfalls in the diagnosis of PE using this modality. This pictorial essay will help to educate imaging physicians about these pitfalls and the associated indirect findings that can point to the presence of this important disease.
-
- 4839 **Computer 88** [The role of Multiparametric prostate MRI in the detection, biopsy, and staging of prostate cancer.](#)

 Mathew Cherny¹ and Robert Villani¹
¹Radiology, Northwell Health, Manhasset, NY, United States
 Prostate cancer is the second cause of cancer related death in men. Historically, screening has consisted of serum PSA, digital rectal exams, and random US guided transrectal biopsy. Compared to older methods, mp-MRI is superior for the detection and staging of prostate cancer due to its improved visualization and lesion characterization. The PI-RADS classification system is a schema developed concordantly with mp-MRI in order to better characterize the clinical significance of imaging findings. Increasingly, mp-MRI is taking a central role in detection, staging and biopsy of prostate neoplasm. In the future it may emerge as a primary screening tool.
-
- 4840 **Computer 89** [Can Thoracic MRI Add Value to Your Practice?](#)

 Chi Wan Koo¹, Darin B White¹, and Geoffrey B Johnson¹
¹Radiology, Mayo Clinic, Rochester, MN, United States
 After reviewing state-of-the art clinical applications of thoracic MRI, reader will become cognizant of potentials and limitations of thoracic MRI and be the judge of whether thoracic MRI can add value to clinical practice.
-
- 4841 **Computer 90** [Magnetic Resonance Imaging Features of Immunoglobulin G4 Related Kidney Disease](#)

 Qiang Huang¹, Jinpeng Liu¹, Feng Chen¹, Wenjie Liang¹, and Wenbo Xiao¹
¹Radiology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, People's Republic of China
 Immunoglobulin G4 related disease (IgG4-RD) is a recently recognized distinct disease entity that can affect many organs/tissues. The kidney is a frequently involved organ with tubulointerstitial nephritis (TIN), and the renal lesions are collectively referred to as IgG4-related kidney disease (IgG4-RKD). Although definitive diagnosis requires histopathologic analysis, imaging plays a crucial role in demonstrating the involved organs/tissues. We retrospectively reviewed the magnetic resonance (MR) imaging findings of 13 patients diagnosed as IgG4-RKD. Various features were assessed, including renal size, margin between cortex and medulla, signal intensity on T1, T2 and diffusion weighted MR images, contrast enhancement, collecting system and/or renal fascia changes. MR imaging features, such as morphology changes, signal intensity abnormality especially on DWI, collecting system and/or renal fascia involvement enables the diagnosis of IgG4-RKD.
-
- 4842 **Computer 91** [A Review of the Magnetic Resonance Findings in Abnormal Placental Implantation.](#)
 Caron Parsons^{1,2} and Charles Hutchinson¹
¹Population, Evidence & Technologies, University of Warwick, Coventry, United Kingdom, ²Department of Radiology, University Hospital Coventry Warwickshire, Coventry, United Kingdom

This presentation will cover the normal anatomy, variants and physiology of the human placenta, as well as magnetic resonance imaging techniques for the evaluation of the placenta, and the spectrum of magnetic resonance findings in abnormal placental implantation. The implications for the mother and foetus will be discussed.

4843

Computer 92 [MRI of Non-obstetric Acute Pelvic Pain in Pregnant Patients](#)

Francisco Lazaga¹, Laura Miller², and Yogesh kumar¹

¹Radiology, Yale New Haven Health Bridgeport Hospital, Bridgeport, CT, United States, ²Yale New Haven Health Bridgeport Hospital, Bridgeport, CT, United States

Acute abdominopelvic pain is a common concern during pregnancy. The differential diagnosis for pelvic pain is extensive and includes multiple non-obstetric etiologies. MRI is effective in evaluating pregnant patients with acute abdominopelvic pain.

MRI provides a complete cross-sectional evaluation of the abdomen and pelvis without radiation exposure or the need for intravenous contrast. MRI can help with the diagnosis in pregnant women with acute pelvic pain expediting treatment, especially when ultrasound results are indeterminate. MRI can also prevent unnecessary surgical exploration which carries a high risk to the pregnancy secondary to preterm uterine contractions.

We provide a list and MR imaging examples of differential diagnoses of acute non-obstetric pelvic pain in pregnancy.

4844

Computer 93 [Quantitative Susceptibility Mapping to Characterise Hepatic Hyperoxia in Mice](#)

Eoin Finnerty¹, Rajiv Ramasawmy¹, James O'Callaghan¹, John Connell¹, Karin Shmueli², David L Thomas³, and Simon Walker-Samuel¹

¹Centre for Advanced Biomedical Imaging, University College London, London, United Kingdom, ²Medical Physics and Biomedical Engineering, University College London, London, United Kingdom, ³Institute of Neurology, University College London, United Kingdom

Information gleaned from Hepatic Venous Oxygen Saturation (ShvO₂) can be beneficial in the post-operative care of those who have undergone a partial hepatectomy. Previously this has been performed invasively. We hypothesise that Quantitative Susceptibility Mapping (QSM) can do so non-invasively. The ShvO₂ of a healthy cohort of mice was manipulated with a hyperoxic gas challenge. Susceptibility was measured under normoxic and hyperoxic conditions, and ShvO₂ was calculated from the measurements. Significant differences were measured in susceptibility and ShvO₂ in response to the gas challenge. We conclude that QSM can non-invasively measure changes in ShvO₂ in the pre-clinical liver in vivo.

4845

Computer 94 [A novel portable perfusion phantom for quantitative DCE-MRI of the abdomen](#)

Harrison Kim¹, Mina Mousa, Patrick Schexnailder, Mark Bolding, Robert Hergenrother, Vinoy Thomas, and Desiree Morgan

¹University of Alabama at Birmingham, Birmingham, AL, United States

We developed a perfusion phantom that reduced variability in quantifying perfusion parameters of human abdominal tissues across different MR units. The phantom is compact enough to be imaged with the human subject and large enough to not suffer from partial volume effect, thus MR system calibration can be implemented simultaneously with patient imaging. Since it is composed of inexpensive materials, the phantom can be constructed as a disposable device. It is simple to use, so clinical MRI technologists should be able to operate it routinely. This phantom has the potential to facilitate multi-institutional clinical trials employing quantitative DCE-MRI to evaluate various abdominal malignancies.

4846

Computer 95 [Semiautomatic determination of arterial input function in breath-hold DCE-MRI of the abdomen](#)

Harrison Kim¹ and Desiree Morgan²

¹University of Alabama at Birmingham, Birmingham, AL, United States, ²University of Alabama at Birmingham

We developed a semiautomatic technique to determine the arterial input function (AIF) in breath-hold DCE-MRI of the abdomen. The error in AIF was significantly reduced by tracking the motion of aorta. Also, we confirmed that the semiautomatic segmentation of the aortic region can reduce error in AIF induced by manual segmentation up to 15%.

4847

Computer 96 [Hepatocellular carcinoma \(HCC\) screening with contrast-enhanced liver MRI: View-sharing artifact reduction with retrospective compressed sensing reconstruction](#)

Paul Benjamin Stoddard¹, Evan Levine², Stephanie T. Chang³, Qiong Song¹, Michael C. Muelly¹, Brian A. Hargreaves², Shreyas S. Vasanawala¹, and Andreas M. Loening¹

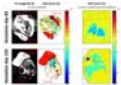

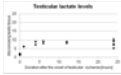

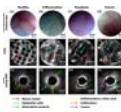

¹Radiology, Stanford University, Stanford, CA, United States, ²Electrical Engineering and Radiology, Stanford University, Stanford, CA, United States, ³Radiology, Veteran Affairs Palo Alto Health Care System

Hepatocellular carcinoma (HCC) screening is a common indication for contrast-enhanced liver MRI. Dynamic contrast-enhanced (DCE) acquisitions often utilize view-sharing (VS) to optimize spatiotemporal resolution, but MRI can often be degraded by respiratory motion. VS introduces temporal blurring of high spatial frequencies that propagate coherent motion artifacts across phases. Compressed sensing (CS) can reduce the need for VS by recovering missing k-space data from pseudo-random undersampling, thus potentially reducing temporal blurring while maintaining spatial resolution. CS results in greatly reduced ghosting artifacts despite a more synthetic appearance.

- 4848 **Computer 97** **Assessing placenta injury with anatomical and IVIM-diffusion MRI in a mouse model of intrauterine inflammation**
Dan Wu¹, Jun Lei², Solange Eloundou², and Irina Burd²
- 
- ¹Radiology, Johns Hopkins University School of Medicine, BALTIMORE, MD, United States, ²Gynecology and Obstetrics, Johns Hopkins University School of Medicine, BALTIMORE, MD, United States
- In this study, we investigated the placenta anatomy and function in a mouse model of intrauterine inflammation, using T2-weighted MRI and introvoxel incoherent motion (IVIM) MRI to measure placental perfusion. The high-resolution T2-weighted images demonstrated altered placenta anatomy in response to the acute inflammatory injury, which agreed with the histological measurements. IVIM of the mouse placenta was acquired with diffusion-weighted echo-planar imaging in a reduced field-of-view. The pseudo-diffusion fraction (f) and coefficient (D^*) fitted from IVIM model indicated reduced perfusion volume (f) and velocity (fD^*) in the injured placentas compared to the shams.

- In the developing fetal lung of both humans and rhesus macaques, the amount of interstitial tissue decreases during the transition from the canalicular to saccular stage. We hypothesize that this change corresponds to a decrease in restricted 1H diffusion in fetal lungs. 17 rhesus fetal lungs (in-vivo and ex-vivo) were imaged at gestation days 83-85, 110, and 133-135 with diffusion-weighted MRI. The apparent diffusion coefficients (ADCs, normalized by free-diffusion) significantly increased with gestational age for both in-vivo and ex-vivo experiments. These results demonstrate that ADC in the fetal lung can be used as a biomarker for the degree of alveolarization.
-
- 4850 **Computer 99** **Magnetic Resonance Spectroscopy of the Testis under Ischemic Condition**
Masayuki Yamaguchi¹, Hidehiro Watanabe², Nobuhiro Takaya², Fumiyouki Mitsumori², and Hirofumi Fujii¹
- 
- ¹Division of Functional Imaging, National Cancer Center, Kashiwa, Japan, ²National Institute for Environmental Studies, Tsukuba, Japan
- Testicular ischemia is an acute disorder, which requires an accurate diagnosis whether the testis function is reversible or irreversible at the time of presentation; however, diagnostic test that predicts the functional reversibility of the ischemic testis has yet been established. This paper reports temporal metabolite changes for up to 24 hours after the onset of experimental testicular ischemia by using a 9.4-tesla magnetic resonance spectroscopy. We found the reduction in creatine levels in the testis under prolonged ischemic condition; hence, the alteration in creatine levels could be a possible metabolite marker that indicates the functional reversibility of the ischemic testis.

- 4851 **Computer 100** **Imaging Seminiferous Tubules in a Mouse Model at 9.4 T – Feasibility for In Vivo Fertility Research**
Mari Herigstad¹, Sofia Granados Aparici², Rachel Rodham³, Allan Pacey², Martyn Paley¹, and Steven Reynolds¹
- 
- ¹Academic Unit of Radiology, University of Sheffield, Sheffield, United Kingdom, ²Department of Oncology and Metabolism, University of Sheffield, Sheffield, United Kingdom, ³Biological Services Unit, University of Sheffield, Sheffield, United Kingdom
- Damage to gonads, including the seminiferous tubules or epididymis, can diminish male fertility. Fertility research often employs mouse models, yet biopsy procedures may sometimes be incompatible with longitudinal studies. A viable non-invasive alternative may be MR. We scanned 8 mice at 9.4T, showing that internal testicular structure can be clearly observed, accurate measurements of seminiferous tubules (volume, diameter) obtained, extra-testicular tissues (e.g. epididymis) identified and spectroscopy peaks spatially localized across different tissues. This indicates that MRI/MRS could be useful in mouse models of fertility and possibly extended to human fertility studies in the future.

- 4853 **Computer 102** **Arterial Spin Labeling imaging of kidney after administration of 2 types of iodinated contrast medium: a time course study in CIN animal models**
Kai Zhao¹, Xueqing Sui¹, Rui Wang¹, Zhiyong Lin¹, Xiaodong Zhang¹, Jian Luo¹, and Xiaoying Wang¹
- ¹Department of Radiology, Peking University First Hospital, Beijing, People's Republic of China

ASL imaging is a preeminent noninvasive method to quantify renal blood flow, which may be helpful to understand the pathogenesis of CIN. Our time course study indicates that the iodinated contrast medium can reduce the blood flow in the different zones of kidney. And some differences do exist on the renal blood flow after the two kinds of iodinated CM administration.

4854 Computer 103 [BOLD imaging of kidney after administration of 2 types of iodinated contrast medium: a time course study in CIN animal models](#)

Kai Zhao¹, Xueqing Sui¹, Rui Wang¹, Zhiyong Lin¹, Xiaodong Zhang¹, Jian Luo¹, and Xiaoying Wang¹

¹Department of Radiology, Peking University First Hospital, Beijing, People's Republic of China

BOLD is a preeminent noninvasive method to quantify renal function, which may be helpful to understand the pathogenesis of CIN. Our time course study indicates that the iodinated contrast medium can induce some affect to the different zone of kidneys. And some differences do exist on the renal oxygen consumption after the two kinds of iodinated CM administration.

4855 Computer 104 [Oxygen Extraction Fraction imaging of kidney after administration of 2 types of iodinated contrast medium: a time course study in CIN animal models](#)

Kai Zhao¹, Xueqing Sui¹, Rui Wang¹, Zhiyong Lin¹, Xiaodong Zhang¹, Jian Luo¹, and Xiaoying Wang¹

¹Department of Radiology, Peking University First Hospital, Beijing, People's Republic of China

MEGSE imaging is a preeminent noninvasive method to quantify renal oxygen extraction fraction, which may be helpful to understand the pathogenesis of CIN. Our time course study indicates that the iodinated contrast medium can increase the OEF in different zones of kidney. And some differences do exist on the renal Oxygen Extraction Fraction (OEF) after the two kinds of iodinated CM administration.

4856 Computer 105 [Comparison of Renal Blood Flow Measurements obtained using ASL-MRI and CT Perfusion](#)

Vanessa L. Landes¹, Christopher M. Ferguson², Hung P. Do¹, John R. Woollard², James D. Krier², Lilach O. Lerman², and Krishna S. Nayak¹

¹University of Southern California, Los Angeles, CA, United States, ²Mayo Clinic, Rochester, MN, United States

Computed tomography perfusion (CTP) is a validated method for assessment of single-kidney renal blood flow (RBF), but is limited by the use of exogenous contrast (i.e. iodine) injection and ionizing radiation. Arterial Spin Labeling (ASL)-MRI is an emerging technique that quantitatively measures RBF without any contrast agents or ionizing radiation. We compared renal perfusion (RBF/gram tissue) obtained using CTP and ASL-MRI in the left and right cortex and medulla of the same pigs (n=6), and observed a linear fit of $ASL-MRI = 0.24 * CTP + 0.42$ ml/ml/min with correlation $r^2=0.71$.

4857 Computer 106 [Intravoxel Incoherent Motion MR Study of Rabbit Liver Fibrosis Model](#)

Lisui Zhou¹, Guangnan Quan², and Xiaocheng Wei²

¹Department of Radiology, Affiliated hospital of Chengdu University, Chengdu, People's Republic of China, ²GE Research China, GE Healthcare, Beijing, People's Republic of China

Staging of liver fibrosis is of great clinical value, because early stage fibrosis is reversible under proper treatment. Liver biopsy, which is currently the golden standard for fibrosis staging, has many limitations. In this study, we evaluated non-invasive IVIM diffusion imaging technique on rabbit liver fibrosis models. As a result, IVIM parameters show significant difference between normal, early and advanced fibrosis liver models. Our study suggests that IVIM parameters have potential to become the biomarker for liver fibrosis staging.

4858 Computer 107 [Assessment of unilateral renal infarction with VTE-ASL in comparison with DCE-MRI](#)

Hanjing Kong¹, Chengyan Wang¹, Fei Gao², Bihui Zhang³, Haochen Wang³, Xiaodong Zhang⁴, Min Yang³, Jue Zhang^{1,2}, Xiaoying Wang^{1,4}, and Jing Fang^{1,2}

¹Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, People's Republic of China, ²College of Engineering, Peking University, Beijing, People's Republic of China, ³Interventional radiology and vascular surgery, Peking University First Hospital, Beijing, People's Republic of China, ⁴Department of Radiology, Peking University First Hospital, Beijing, People's Republic of China

DCE-MRI and ASL are promising method in evaluating renal disease. However, their application on renal infarction is lagging behind. In this study, we aim to investigate the value of VTE-ASL and DCE-MRI in renal infarction assessment and further compare the results with histological findings.

4859 Computer 108 [Whole body, high throughput mouse embryo 3D phenotyping using multi gradient echo and ultra short echo time with computed tomography validation.](#)

Orlando Aristizabal¹, Dung Minh Hoang², Sebastian Mendoza³, Daniel H. Turnbull², and Youssef Zaim Wadghiri²

¹Structural Biology, Skirball Institute of Biomolecular Medicine, New York, NY, United States, ²Radiology, NYU School of Medicine, ³NYU School of Medicine

In this study a combination of 3D multi gradient echo (MGE) and ultrashort echo time (UTE) 100 micron isotropic resolution were acquired from 6 fixed mouse embryos at embryonic day 16. The embryos were littermates from an engrailed knockout mouse whose mutant embryos die at birth. The data from the UTE was validated with a high resolution CT scan. Results verify the utility of this approach to image both soft tissue and the skeletal system in a high throughput manner. The expected phenotype was easily identifiable and the 3D reconstruction of the skeletal system was equivalent to CT.

- 4860 Computer 109 Evaluation of unilateral obstructive uropathy using co-polarized 13C-pyruvate and 13C-urea
Per Mose Nielsen¹, Rikke Nørregaard², and Christoffer Laustsen¹

¹MR Research Centre, Skejby University hospital, Aarhus N, Denmark, ²Clinical institute, Skejby University hospital, Aarhus N, Denmark

Unilateral obstructive uropathy (UJO) is a cause of acute kidney injury and can also lead to chronic kidney diseases. A common cause for UJO is kidney stones and is also often the cause of end-stage renal diseases in children because of congenital development defects. Here we used a unilateral obstruction model with obstruction release after 5 days, and injection of co-polarized 13C-pyruvate and 13C-urea 2 days after release. We saw a marked elevation in lactate/pyruvate ratio in the UJO kidney of the animals and also a reduction of approx. 50% in kidney bloodflow measured by 13C-urea. The mechanisms involved must be investigated further. We believe that injection of co-polarized 13C-pyruvate and 13C-urea can be used as a clinical tool to follow kidney metabolic status and bloodflow after surgical release of ureter obstruction.

- 4861 Computer 110 Evaluation of renal oxygenation change by functional MRI with administration of furosemide in diabetic nephropathy model
Rui Wang¹, Zhiyong Lin¹, and Xueqing Sui¹

¹Radiology, Peking University First Hospital, Beijing, People's Republic of China

Our study was to assess renal hemodynamics and oxygenation using blood oxygen level dependent (BOLD) and oxygen extraction fraction (OEF) imaging in diabetic nephropathy (DN) rabbits following administration of furosemide.

- 4862 Computer 111 A multicenter in vivo study to evaluate gadoxetate DCE-MRI as a preclinical biomarker of liver function

¹Antaros Medical, Molndal, Sweden, ²MedTech West, Chalmers University of Technology, Gothenburg, Sweden, ³AstraZeneca, Molndal, Sweden, ⁴GlaxoSmithKline, King of Prussia, PA, United States, ⁵Amgen Inc., Thousand Oaks, CA, United States, ⁶Linköping University, Linköping, Sweden, ⁷Wolfram MathCore, Linköping, Sweden, ⁸National Center for Toxicological Research, U.S. Food and Drug Administration, Jefferson, AR, United States, ⁹AbbVie, North Chicago, IL, United States, ¹⁰AstraZeneca, Cambridge, United Kingdom, ¹¹University of North Carolina, Chapel Hill, NC, United States

Gadoxetate dynamic contrast-enhanced MRI (DCE-MRI) seems promising for non-invasive quantification of liver function. Here we tested the reproducibility of gadoxetate DCE-MRI at four MRI sites using an acute clinical dose of the antibiotic rifampicin. We found significant differences between sites in maximum relative enhancement (RE) in vehicle treated rats. However, highly significant differences in maximum RE between vehicle and rifampicin treated rats was detected at all sites. To our knowledge this is the first multicenter preclinical reproducibility study of an imaging biomarker.

- 4863 Computer 112 Characterization of renal parenchyma impairment in partial unilateral ureteral obstruction in mice with Intravoxel Incoherent Motion MR imaging
Maguelonne Pons¹, Benjamin Leporq², Liza Ali³, Marianne Alison³, Miguel Albuquerque¹, Michel Peuchmaur⁴, Marie-Laurence Poli Mérol⁵, Ulrich Blank¹, Simon Auguste Lambert², and Alaa El Ghoneimi⁴

¹INSERM UMR 1149, Paris, France, ²Univ Lyon, INSA-Lyon, Université Claude Bernard Lyon 1, ³Hôpital Robert Debré, APHP, Université Paris Diderot, Sorbonne Paris Cité, ⁴Pediatric Surgery and Urology, Hôpital Robert Debré, APHP, Université Paris Diderot, Sorbonne Paris Cité, ⁵Université Reims Champagne Ardennes, American Memorial Hospital

Ureteropelvic junction obstruction constitutes a major cause of progressive pediatric renal disease. To date the follow-up of patients is difficult because there is a lack of non-invasive biomarkers. Here we propose to quantitatively characterize impairment of the kidney parenchyma after partial unilateral ureteral obstruction (pUUO) on mice using an intravoxel incoherent motion diffusion sequence. The results suggest that an f reduction is associated with a decrease in the volume of the renal parenchyma, which could be related to decreased renal vascularization. The later may occur before impairment by fibrosis and the findings are in accordance with the literature on pUUO.

- 4864 Computer 113 Evaluation of compressed sensing for 3D T1-weighted fat-suppressed breast MRI
Courtney K. Morrison¹, Jacob M. Johnson², Yuji Iwadate³, Kevin King⁴, James H. Holmes², Frank R. Korosec^{1,2}, Roberta M. Strigel^{1,2,5}, and Kang Wang⁶

Spatial resolution has typically been prioritized at the expense of temporal resolution in the setting of dynamic contrast-enhanced breast MRI. In this work, we evaluated the use of compressed sensing (CS) with intermittent fat suppression for improved temporal resolution by comparing quality of fat suppression and overall image quality between a sequence accelerated using CS to one without CS.

Pulmonary fibrosis has high morbidity and mortality, but remains poorly understood. Many experimental and clinical studies have implied or demonstrated the role for transforming growth factor (TGF)- α in the pathogenesis of pulmonary fibrosis. We demonstrate the utilization of retrospective self-gating UTE MRI with ellipsoidal k-space coverage to measure the burden of pulmonary fibrosis in a TGF- α transgenic mouse model, with the dynamic progression of fibrotic burden well quantified longitudinally by both high-density lung volume percentage and tidal volume.

Ferumoxytol-enhanced MRI may enable the assessment of altered immune cell activation and distribution in placental inflammation. In this work, quantitative susceptibility mapping (QSM) is proposed to assess the temporal variation of ferumoxytol concentration in the placenta. Three healthy pregnant rhesus monkeys were imaged at six time points relative to ferumoxytol injection. Longitudinal quantification of placental magnetic susceptibility and R1/R2/R2* relaxometry were performed to provide a preliminary assessment of the ferumoxytol variation in healthy rhesus placenta. This study demonstrated the feasibility of ferumoxytol-enhanced QSM and relaxometry in the rhesus placenta and may provide a method for the evaluation of placental inflammation.

Multi-parametric MRI techniques may allow the assessment of renal injury and function in a sensitive and objective manner. This study aimed to evaluate an array of MRI methods that exploit endogenous contrasts for their sensitivity in detecting abnormal features associated with kidney disease in a murine model of unilateral ureter obstruction (UUO). Diffusion weighted imaging (DWI), quantitative magnetization transfer (qMT), chemical exchange saturation transfer (CEST), and nuclear Overhauser enhancement (NOE) provide specific information about the cellular and molecular changes produced by UUO.

Reversible Changes in Cardiac Function and Metabolism in an Inducible Mouse Model of Type 1 Diabetes

Dragana Savic¹, Maria Rohm, Vicky Ball, Mary Kate Curtis, Lisa Heather, Frances M Ashcroft, and Damian J. Tyler

¹University of Oxford, Oxford, United Kingdom

Heart disease is the leading cause of death in Type 1 diabetic patients, however the mechanistic link has not been fully established. In this study an inducible and reversible mouse model of Type 1 diabetes was used. Depression of cardiac function and the increase in blood glucose occur in combination with suppression of pyruvate to bicarbonate conversion. By reversing diabetes with Glibenclamide, cardiac function and blood glucose concentration was restored. This study demonstrated changes that occur alongside the development of a reversible model of Type 1 diabetes and how the action of Glibenclamide can affect metabolism and function of the heart.

Computer 2

Type 1 Diabetic Hearts show Unexpected Biphasic Metabolic and Functional Progression as Evaluated with Hyperpolarised [1-13C]Pyruvate and CINE MR.

Dragana Savic¹, Vicky Ball, Carolyn Carr, Lisa Heather, and Damian J. Tyler

¹Department of Physiology, Anatomy & Genetics, University of Oxford, Oxford, United Kingdom

Type 1 diabetes patients are insulin deficient resulting in hyperglycaemia. Diabetic patients have a higher risk of cardiovascular diseases. In this study the progression of cardiac metabolic and functional decline was followed in a streptozotocin (STZ) induced Type 1 diabetic model. Flux through pyruvate dehydrogenase was significantly decreased at 2 and 6 weeks post STZ injection. Interestingly, the incorporation of the ¹³C-label from pyruvate into lactate and alanine was decreased at 2 weeks, but significantly increased at 6 weeks. Cardiac output was normalized after 6 weeks. Such studies will allow a better understanding of the interactions between metabolism and function in the diabetic heart.

Repeatability and User Variability of Myocardial Tissue Phase Mapping in Mice

Nivedita K. Naresh¹, Cynthia Yang¹, Sol Misener¹, Bradley D. Allen¹, Michael Markl^{1,2}, James C. Carr^{1,3,4}, and Daniele Prociissi¹

¹Radiology, Northwestern University, Chicago, IL, United States, ²Biomedical Engineering, Northwestern University, Chicago, IL, United States, ³Medicine, Northwestern University, Chicago, IL, United States, ⁴McCormick School of Engineering, Northwestern University, Chicago, IL, United States

Mouse models can help investigate the molecular mechanisms underlying complex cardiovascular diseases. Assessment of myocardial regional wall motion plays a very important role in the diagnosis and management of several cardiovascular diseases and can be linked to many underlying biological processes. In this study, we evaluated the repeatability and inter-user variability of the myocardial tissue phase mapping method in mice. We found that myocardial tissue phase mapping can be performed with good repeatability and little user variability in mice to reliably quantify both global and regional myocardial velocities.

MRI/PET of Myocardial Extracellular Volume in a Canine model of Chemotherapy

Chia-Ying Liu¹, Cynthia Davies-Venn¹, Comfort Elumogo¹, Rolf Symons¹, Victoria Hoffmann², Kelly Rice², Roberto Maass-Moreno¹, Veit Sandfort¹, Stefan Zimmermann³, Amir Pourmorteza¹, Mark Ahlman¹, and David Bluemke¹

¹Radiology and Imaging Sciences, National Institutes of Health, Bethesda, MD, United States, ²Division of Veterinary Resources, National Institutes of Health, ³Department of Radiology, Johns Hopkins Hospital, MD, United States

We used simultaneous MR/FDG PET to measure the myocardial extracellular volume (ECV) and glucose metabolism (estimated by standard uptake value, SUV) in a canine model of chemotherapy (ChT); comparison was made to ECV in relationship to a myocardial infarct (MI) models. MRI ECV in the ChT group was elevated by 16% and 23% compared to the MI group in the remote and adjacent myocardial segments, respectively. PET SUV in the ChT group was reduced by 49% and 41% compared to the MI group in the remote and adjacent myocardial segments, respectively. Difference was also observed in the MRI partition coefficient but not in the native T1.

Evaluation of the impact of strain correction on the secondary eigenvector of diffusion with *in vivo* and *ex vivo* porcine hearts

Pedro Ferreira¹, Sonia Nelles-Vallespin², Ranil de Silva¹, Andrew Scott¹, Daniel Ennis³, Daniel Auger⁴, Jonathan Suever⁵, Xiaodong Zhong⁶, Bruce Spottiswoode⁷, Dudley Pennell¹, Andrew Arai², and David Firmin¹

¹Cardiovascular BRU, Royal Brompton Hospital, London, United Kingdom, ²NHLBI, National Institutes of Health, MD, United States, ³Department of Radiological Sciences, UCLA, CA, United States, ⁴Biomedical Engineering, University of Virginia, VA, United States, ⁵Geisinger Medical Center, PA, United States, ⁶Siemens Healthcare, GA, United States, ⁷Siemens Healthcare, TN, United States

Myocytes have a laminar organization, where sheets of myocytes interleave with collagen-lined shear layers. Cardiac diffusion tensor imaging is capable of probing sheet dynamics with secondary diffusion directions, although questions remain about cardiac strain being a possible confounder. Here we study the validity of strain-correcting cardiac diffusion tensor data by directly comparing *in vivo* DTI data without and with strain correction, to *ex vivo* DTI data of the same porcine hearts arrested in a diastolic or systolic conformation. Results show that the current strain correction model exaggerates the contribution of microscopic strain to diffusion resulting in an over-correction.

Simultaneous Cardiac and Renal oblique-slice T1-Mapping Differentiates Contrast Agent Activity in Normal and Doxorubicin-treated Rats

Ronald J Beyers¹, Dean Schwartz², Tessa Hutchinson³, Meghan Ward³, Nouha Salibi^{1,4}, Christian Goldsmith³, and Thomas Denney¹

¹MRI Research Center, Auburn University, Auburn, AL, United States, ²Department of Anatomy, Physiology and Pharmacology, Auburn University, Auburn, AL, United States, ³Department of Chemistry and Biochemistry, Auburn University, Auburn, AL, United States, ⁴MR R&D, Siemens Healthcare, Malvern, PA, United States

We developed a cardiac multi-oblique-slice T1-mapping sequence, called *Tmax*, for simultaneous *in vivo* cardiac and multi-region T1-mapping in rats. We validated *Tmax* with gadolinium contrast agent (CA) scans then applied it to support our concurrent development of a reactive oxygen species activated T1-shortening agent, called H4qtp2, in doxorubicin-treated (Dox) rats. The new *Tmax* sequence performed excellent at simultaneously quantifying gadolinium T1 effects in cardiac and renal regions. However, application of *Tmax* with low dose levels of H4qtp2 CA in Dox rats gave marginal results from too low dose of H4qtp2 to sufficiently affect the T1 and quantify Dox-induced pathology

In this work we wanted to test a Magnetic Resonance (MR) scanning protocol as a non-invasive tool to determine hepatic hemodynamics and to assess the liver fibrosis degree in an animal model of liver fibrosis and cirrhosis. MR rat liver images provided a good discrimination of healthy from diseased liver, but for the assessment of liver fibrosis degree histology is indispensable. The results show that portal and aortal flow patterns for a cardiac cycle could be measured with high reliability. In Conclusion, this MR scanning protocol presents a reliable non-invasive tool to determine hepatic hemodynamics in healthy and diseased rats

4D-Flow MRI is introduced as an alternative to Doppler velocimetry in monitoring blood flow to the placenta in pregnancy. Our 3D radially undersampled PC-VIPR technique provided volumetric coverage of uterus and relevant vasculature with a 10-minute scan. Uterine arteries and ovarian veins were visualized in a 0.83mm isotropic resolution angiogram and flow rates and vessel sizes were measured retrospectively. Repeated scans of four rhesus macaques on subsequent days showed reproducibility of flow rate and cross sectional area measurements in vessels of interest, demonstrating the potential for 4D-Flow MRI for assessing utero-placental vascular health.

4D flow MRI measurements in *ex vivo* beating pig hearts as a testing platform for transcatheter aortic valve implantation

Eva S Peper¹, Alberto Leopaldi², Sjoerd van Tuijl², Nicky de Jonge², Gustav J Strijkers³, Arend de Weger⁴, Aart J Nederveen¹, Henk A Marquering³, and Pim van Ooij¹

¹Department of Radiology, Academic Medical Center, Amsterdam, Netherlands, ²LifeTec Group, Eindhoven, the Netherlands, Netherlands, ³Department of Biomedical Engineering & Physics, Academic Medical Center, Amsterdam, Netherlands, ⁴Department of Cardiothoracic Surgery, Leiden University Medical Center, Leiden, Netherlands

In this 4D flow MRI study, ex vivo beating pig heart models in an MR-compatible setup mimicking human physiological conditions were used to investigate flow alterations after implantation of artificial valves designed for transcatheter aortic valve implantations (TAVI). Two pig hearts had implanted TAVI valves (one with and one without attachment to the aortic sinuses) and were compared to five pig hearts without valve implantation. For both pig hearts with implanted valves, substantial aortic backflow, and thus paravalvular leakage, was observed. The ex vivo set-up presented is thus suitable for cardiac flow experiments.

Evaluation of accelerated preclinical 4D-flow imaging with UNFOLD

Moritz Braig¹, Axel J. Krafft¹, Jochen Leupold¹, Juergen Hennig¹, Marius Menza¹, and Dominik von Elverfeldt¹

¹Medical Physics, University Medical Center Freiburg, 79106, Germany

There is growing interest in preclinical imaging and analysis of complex flow patterns. For example, 4D flow imaging of mouse models with vascular plaques or aortic constriction could provide insights into the development and pathogenesis of cardiovascular diseases. Unfortunately, 4D-flow MRI is often compromised by a trade-off of reasonable acquisition durations and achievable spatial resolution. Our work evaluates an undersampling strategy, namely UNFOLD, for preclinical 4D flow MRI, which has the potential to decrease measurement time by 50%. Artifacts emerging from the undersampling are removed by unaliasing in the temporal domain using a lowpass filter after fourier transformation.

Quantitative gated and non-gated rat phase contrast MRI: optimized analysis of blood flow and wall shear stress.

Chen-You Huang¹, Chiun-Wei Huang², Shao-Chieh Chiu², Wu-Chung Shen¹, and Shin-Lei Peng¹

¹Department of Biomedical Imaging and Radiological Science, China Medical University, Taichung, Taiwan, ²Center for Advanced Molecular Imaging and Translation, Chang Gung Memorial Hospital

Goals of this study are to test effects of gated/non-gated, velocity encoding (VENC) and spatial resolution on blood flow, wall shear stress (WSS) and artery area when performing phase-contrast (PC) MRI for rat common carotid artery (CCA). Results show the usage of gated instrument can provide more reproducible results. VENC has insignificant influences on flow, WSS and artery area. To compromise the trade-off between accuracy and time-consuming, the resolution of 0.21 mm is suggested for extracting hemodynamic information about rat CCA.

4883

Computer 12

Right ventricular myocardial strain in rats

Emil Espe¹, Jan Magnus Aronsen^{1,2}, Lili Zhang¹, and Ivar Sjaastad¹

¹Institute for Experimental Medical Research, University of Oslo, OSLO, Norway, ²Bjorknes College, Oslo, Norway

The function of the right ventricle (RV) is closely linked to clinical outcome in many cardiovascular diseases. Experimental heart disease in rodents play an irreplaceable role in modern cardiovascular research, but no in vivo method exists offering robust measurements of RV myocardial function in small animals.

We used phase-contrast MRI to measure RV strain in rats. We found that RV strain and ejection fraction were closely related, and confirmed that high RV afterload is linked to reduced RV strain.

We show, for the first time, that it is possible to accurately measure myocardial function in the RV in rodents.

4884

Computer 13

Cardiac MRI measurement of right ventricular strain using feature tracking in a model of embolic pulmonary hypertension.

Zachary Borden¹, Donald Benson¹, Alejandro Roldan², Heidi Kellihan³, Ashley Mulchrone⁴, Naomi Chesler⁴, and Christopher Francois¹

¹Radiology, University of Wisconsin-Madison, Madison, WI, United States, ²Radiology and Medical Engineering, University of Wisconsin-Madison, Madison, WI, United States, ³Veterinary Medicine, University of Wisconsin-Madison, Madison, WI, United States, ⁴Biomedical Engineering, University of Wisconsin-Madison, Madison, WI, United States

Right ventricular strain was assessed using an MRI tissue tracking algorithm on bSSFP axial sequences in both acute and chronic embolic pulmonary hypertension canine models. Strain values were heterogeneous in the acute population with statistically significant decreases in acute radial and longitudinal strain rate and chronic radial and longitudinal strain and strain rate values. Findings suggest MRI cardiac strain measurement is a promising technique in the clinical evaluation of post embolic pulmonary hypertension patients.

Cardiac Magnetic Resonance for Characterizing a Spontaneous Hypertrophic Cardiomyopathy Mouse Model

Min-Chi Ku¹, Till Huelnhagen¹, Andreas Pohlmann¹, and Thoralf Niendorf^{1,2,3}

¹Berlin Ultrahigh Field Facility, Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany, ²Experimental and Clinical Research Center, Charite Medical Faculty and the Max Delbrueck Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany, ³DZHK (German Centre for Cardiovascular Research), partner site Berlin, Germany

HCM is the most common inherited heart disease. The two most frequently seen mutated genes are MYH7 and MYBPC3 which account for nearly 80% of familiar HCM. In this study we hypothesized that these gene variants will affect both LV and RV function. By *in-vivo* CMR we detected LV hypertrophy in a mouse strain DBA/2J bearing the two gene variants. Interestingly there is no defected LV function found but changes in RV function as both male and female DBA/2J mice had declined RVEF. Our results provide new insights into the correlation of genetic alteration and HCM phenotype.

4D Cine Strategy for Assessment of Mouse Cardiac Function and Infarct Size in a Single Acquisition Optimized for a Clinical 3T MR System

Lindsey A Crowe¹, Fabrizio Montecucco², Federico Carbone², Iris Friedli¹, Anne-Lise Hachulla¹, Vincent Braunersreuther³, Francois Mach³, and Jean-Paul Vallée¹

¹Department of Radiology, Geneva University Hospitals, Geneva, Switzerland, ²Department of Internal Medicine, University of Genoa, Italy, ³Department of Cardiology, Geneva University Hospitals, Geneva, Switzerland

Small cardiac imaging on clinical 3T machines is an important, cost effective translational step for new contrast media and sequence validation. We developed for the first time a new 4D strategy tailored for 3T to simultaneously assess function and infarct in mice, validated against 2D cine, post mortem and histology. Isotropic 3D cardiac cine of mice on a clinical 3T system improved coverage and reduced flow artifacts with higher spatial and temporal resolution for more accurate quantification of cardiac function. Infarct volume enhancement was quantifiable from the same 3D cine acquisition.

Gadobutrol- vs. gadoterate meglumine-enhanced multi-phase 3D-MRA and 4D-MRA at 1.5T and 3T: an intra-individual quantitative and qualitative comparison of macrocyclic contrast agents in minipigs

Dariusch Reza Hadizadeh¹, Gregor Jost², Vera Catharina Keil¹, Christian Marx¹, Maximilian Rauch¹, Frederic Carsten Schmeel¹, Hubertus Pietsch², Hans Heinz Schild¹, and Winfried Albert Willinek³

¹Radiology, University of Bonn, Bonn, Germany, ²MR and CT Contrast Media Research, Bayer Pharma AG, Berlin, Germany, ³Zentrum für Radiologie, Neuroradiologie, Sonographie und Nuklearmedizin, Krankenhaus der barmherzigen Brüder, Trier, Germany

In an animal model bolus kinetics and image quality of the macrocyclic contrast agents (CA) gadobutrol (standard and half-dose) and gadoterate meglumine (standard-dose) were investigated intra-individually in multi-phase 3D- (MP3D) MRA and in 4D-MRA at 1.5T and 3T. Standard dose gadobutrol provided significantly higher signals in both MP3D- and 4D-MRA at both field strengths. Differences were most prominent in venous imaging phases. At 3T, arterial first pass peaks were truncated in 7/8 minipigs using standard dose CA. Image quality analysis of MP3D confirmed higher image quality in venous phases with standard-dose gadobutrol compared to gadoterate meglumine at both field strengths.

¹Affiliated hospital of Guangdong Medical College, Zhanjiang, People's Republic of China, ²Sun Yat-Sen Memorial Hospital, Guangzhou, People's Republic of China, ³Tsinghua University, Beijing, People's Republic of China, ⁴Shiyan People's Hospital, ⁵Peking University Shenzhen Hospital, ⁶Sun Yat-Sen Memorial Hospital, ⁷The Fifth Affiliated Hospital of Sun Yat-Sen University, ⁸Philips Healthcare, Hong Kong, ⁹Philips Healthcare, Guangzhou, ¹⁰Tsinghua University

Whether there exists a lag in the iron loading between liver and heart in transfusion dependent patients has clinical significance in prevention and treatment of heart iron overload. We performed this study to verify this time lag on a rabbit model. The result shows that the iron loading, measured with pathology, MRI and atomic absorption spectrophotometer, was much faster and heavier in the liver than that in the heart. Therefore, there existed a time lag between heart and liver iron overload on the rabbit model. This may lead to improved clinical guidelines for cardioprotection.

Computer 18

Multiparametric CMR protocol and analysis methods for the detection of early cardiotoxicity remodelling in the mini-swine.

Delphine Perie¹, Clémence Balosetti¹, Hélène Héon², Nagib Dahdah³, Farida Cheriet¹, Matthias Friedrich⁴, and Daniel Cumier⁵

¹Mechanical Engineering, Polytechnique Montreal, Montreal, QC, Canada, ²Research Center, CHUM, Montreal, QC, Canada, ³Pediatric cardiology, CHU Sainte-Justine, Montreal, QC, Canada, ⁴Health Center, McGill University, Montreal, QC, Canada, ⁵Kinesiology, Université de Montréal, Montreal, QC, Canada

Some Cardiovascular magnetic resonance (CMR) studies investigated the long term effects of cancer treatments, but were never applied to the detection of early changes during cardiotoxicity remodelling. The CMR parameters we investigated in the miniature swine therapeutic model with doxorubicin was able discriminate treated animals from controls. Differences were detectable earlier than onset of classical echocardiographic changes. Translating these observations to personalized medicine approach could be the premise for the oncologist to know accurately when the treatment just starts to have deleterious effect on myocardium instead of just observing that the heart was damaged by doxorubicin.

¹Translational Biomarkers, Merck Sharp & Dohme, Singapore, Singapore, ²Cardiovascular Research Institute, National University Heart Centre, Singapore, ³Department of Surgery, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, ⁴Comparative Medicine Imaging Facility, Center for Life Sciences, National University of Singapore, Singapore, ⁵Translational Biomarkers, Merck & Co., Inc., West Point, PA, United States

We characterized cardiac structure and function longitudinally in myocardial infarcted pigs, induced by permanent ligation of left circumflex artery of left ventricle (LV), to identify early strain biomarkers that are predictive of late stage remodeling. Pigs were imaged pre- and post-surgery at 1-wk and 4-wk. Reduction of percentage of infarct was observed at basal antero-lateral and mid infero-lateral regions at 4-wk post-surgery. Decreased peak circumferential strain was observed at infarcted areas showing compromised contractility. In addition, ROC analyses revealed that acute strain at 1-wk and early strain change from baseline can predict chronic infarct size suggesting that LV strain could potentially serve as early biomarker for novel therapies.

T1 Mapping with Nitric Oxide Synthase (NOS) Inhibition Detects Impaired Coronary Endothelial Function in Mice Fed a High Fat Diet

Sophia Xinyuan Cui¹ and Frederick H. Epstein^{1,2}

¹Biomedical Engineering, University of Virginia, Charlottesville, VA, United States, ²Radiology, University of Virginia, Charlottesville, VA, United States

Endothelial nitric oxide synthase (eNOS)-mediated production of NO regulates the microvasculature, controlling both vessel diameter and permeability. We hypothesized that T1 mapping of the healthy heart during NOS inhibition would detect increased water content resulting from increased coronary microvascular permeability, while a blunted change in T1 between baseline and NOS inhibition would indicate coronary eNOS dysfunction. Using these methods, we detected an increase in myocardial T1 of 113 ± 15 ms due to NOS inhibition in control mice, but no change in eNOS^{-/-} or HFD mice, demonstrating the eNOS mechanism and detection of coronary endothelial dysfunction in a model of heart disease.

Comparison of Differentiation Capability among CEST Imaging, DWI and FDG-PET/CT in Patients with Pulmonary Lesions

Yoshiharu Ohno^{1,2}, Masao Yui³, Mitsue Miyazaki⁴, Yuji Kishida⁵, Sinichiro Seki^{1,2}, Katsusuke Kyotani⁶, and Takeshi Yoshikawa^{1,2}

¹Division of Functional and Diagnostic Imaging Research, Department of Radiology, Kobe University Graduate School of Medicine, Kobe, Japan, ²Advanced Biomedical Imaging Research Center, Kobe University Graduate School of Medicine, Kobe, Japan, ³Center for Medical Research and Development, Toshiba Medical Systems Corporation, Otawara, Japan, ⁴MR Research, Toshiba Medical Research Institute USA, Vernon Hills, IL, United States, ⁵Division of Radiology, Department of Radiology, Kobe University Graduate School of Medicine, Kobe, Japan, ⁶Center for Radiology and Radiation Oncology, Kobe University Hospital, Kobe, Japan

Chemical exchange saturation transfer (CEST) imaging is suggested as a new technique for MR-based molecular imaging techniques in vivo and in vitro studies. We hypothesized that newly developed CEST imaging may have a similar potential for differentiating malignant from benign pulmonary nodules and masses, when compared with DWI and FDG-PET/CT. The purpose of this study was to directly and prospectively compare the differentiation capability among CEST imaging, DWI and FDG-PET/CT in patients with pulmonary lesions.

Computer 26

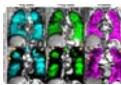

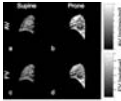

Comparison of the Capability for Quantitative Distinguishing Malignant from Benign Pulmonary Nodules among Dynamic First-Pass CE-Perfusion ADCT and MRI and FDG-PET/CT

Yoshiharu Ohno^{1,2}, Yuji Kishida³, Sinichiro Seki^{1,2}, Shigeharu Ohyu⁴, Masao Yui⁴, Wakiko Tani⁵, Noriyuki Negi⁵, Katsusuke Kyotani⁵, and Takeshi Yoshikawa^{1,2}

¹Division of Functional and Diagnostic Imaging Research, Department of Radiology, Kobe University Graduate School of Medicine, Kobe, Japan, ²Advanced Biomedical Imaging Research Center, Kobe University Graduate School of Medicine, Kobe, Japan, ³Division of Radiology, Department of Radiology, Kobe University Graduate School of Medicine, Kobe, Japan, ⁴Center for Medical Research and Development, Toshiba Medical Systems Corporation, Otawara, Japan, ⁵Center for Radiology and Radiation Oncology, Kobe University Hospital, Kobe, Japan

Quantification of perfusion parameter from dynamic CE-perfusion MRI at 3T system may be more difficult than that at 1.5T system, and contrast media concentration may have larger influence to measurement error of perfusion parameter on a 3T system. We hypothesized that a bolus injection protocol with appropriately small contrast media volume can provide accurate pulmonary perfusion parameter on dynamic CE-perfusion MRI at a 3T system. The purpose of this study was to determine the appropriate contrast media volume for quantitative assessment of dynamic CE-pulmonary MRI, when compared with dynamic CE-area-detector CT (ADCT) for quantitative evaluation of perfusion within whole lung.

- 4896 **Computer 27** [Asthma Ventilation Abnormalities Measured using Fourier-Decomposition Free-breathing Pulmonary ¹H MRI](#)

 Dante PI Capaldi¹, Khadija Sheikh¹, Rachel L Eddy¹, Sarah Svenningsen¹, Miranda Kirby², David G McCormack³, Grace Parraga¹, and Canadian Respiratory Research Network
¹Robarts Research Institute, London, ON, Canada, ²Centre for Heart Lung Innovation, Vancouver, ON, Canada, ³Division of Respiriology, University of Western Ontario, London, ON, Canada
- Hyperpolarized noble-gas-MRI provides a way to visualize and regionally measure ventilation-heterogeneity in asthma, which has been shown to be sensitive to treatment response. Fourier-decomposition of free-breathing ¹H MRI (FDMRI) has been proposed as an alternative way to evaluate regional-ventilation without the need for exogenous contrast. We hypothesized that ventilation-abnormalities would be qualitatively and quantitatively similar between the two imaging methods, and hence our objective was to measure ventilation-defects using FDMRI in asthma patients for comparison with inhaled-gas-MRI. Preliminary results in asthma showed that FDMRI ventilation-abnormalities were related to hyperpolarized noble-gas-MRI and clinical measurements of ventilation-heterogeneity in severe-asthmatics.

- 4897 **Computer 28** [Multicentre repeatability of ADC estimates from diffusion weighted \(DW\) MRI in lung cancer: influence of segmentation methodology and statistical descriptor](#)

 Alexander Weller¹, M-V Papoutsaki¹, JC Waterton², Arturo Chiti³, Matthew Blackledge¹, Matthew Orton¹, David Collins¹, and Nandita de-Souza¹
¹Radiotherapy and Imaging, The Institute of Cancer Research, Surrey, United Kingdom, ²Centre for Imaging Sciences, Division of Informatics Imaging & Data Sciences, University of Manchester, MANCHESTER, United Kingdom, ³Department of Biomedical Sciences, Humanitas University, Rozzano (Milano), Italy
- Using a multi-platform diffusion weighted MRI protocol in lung tumors, apparent diffusion coefficient (ADC) repeatability was well below the change expected for treatment response. ADC coefficients of variation (CoV) varied depending on lesion size and segmentation methodology (range 2.6-10.8%; three times greater for lesions >3cm than lesions <3cm). Performing tumor segmentation on high-b-value images produced lower, more repeatable ADC estimates than if segmenting on low-b-value images. Using median versus mean statistical descriptors for signal averaging prior to ADC calculation did not affect ADC quantitation or repeatability.
-
- 4898 **Computer 29** [Retrospective Image Sorting for Phase REsolved Lung Perfusion Imaging \(PRELP\)](#)

 Andreas Voskrebenev^{1,2}, Marcel Gutberlet^{1,2}, Filip Klimes^{1,2}, Till Kaireit^{1,2}, Alexander Rotärmel^{1,2}, Christian Schönfeld^{1,2}, Frank Wacker^{1,2}, and Jens Vogel-Claussen^{1,2}
¹Diagnostic and Interventional Radiology, Medical School Hannover, Hannover, Germany, ²Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), German Center for Lung Research (DZL), Hannover, Germany
- Currently, only self-gated or ultra-fast sequences allow an adequate temporal resolution to resolve different cardiac phases during lung perfusion. First studies show the benefit of this additional information. Nevertheless such techniques are not widely available. Therefore, in this study a post processing method is assessed, which can increase the temporal resolution by sorting images according to their cardiac phase using a piecewise cosine fit. The feasibility is demonstrated in 6 healthy volunteers and two patients with chronic thromboembolic hypertension (CTEPH). The easy implementation and possibility of retrospective evaluation of existing Fourier Decomposition acquisitions are the advantages of this method.
-
- 4899 **Computer 30** [Free Breathing Regional Alveolar Ventilation Quantification - comparison to Fractional Ventilation derived by Fourier Decomposition Lung MRI](#)

 Filip Klimes^{1,2}, Andreas Voskrebenev^{1,2}, Marcel Gutberlet^{1,2}, Agilo Kern^{1,2}, Till Kaireit^{1,2}, Alexander Rotärmel^{1,2}, Frank Wacker^{1,2}, and Jens Vogel-Claussen^{1,2}
¹Institute of Radiology, Hannover Medical School, Hannover, Germany, ²Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Hannover, Germany
- Fourier Decomposition (FD) is able to assess lung ventilation and perfusion in one free breathing measurement without any contrast agent. To establish a ventilation-perfusion (VQ) scan robust measurements and absolute quantification is required. Unlike for absolute perfusion quantification, there has been only little success regarding absolute ventilation quantification using FD MRI. Borrowing concepts from oxygen enhanced imaging a regional alveolar ventilation measurement in free breathing is introduced. This method is compared with Fractional Ventilation (FV) and tested for physiological plausibility by assessment of volunteers in supine and prone position. The results show good agreement with available literature and show a similar gravitational behaviour as FV.
-
- 4900 **Computer 31** [Impact of Helium-Oxygen Inhalation on Aerosol Deposition in Asthmatic Rats using UTE-MRI](#)

 Hongchen Wang¹, Felicia Julea¹, Georges Willoquet¹, Catherine Sebré¹, Sébastien Judé², Anne Maurin², Stéphanie Rétif³, Sharuja Natkunarajah³, Stéphanie Lerondel³, Rose-Marie Dubuisson¹, Luc Darrasse¹, Geneviève Guillot¹, Ludovic de Rochefort¹, and Xavier Maître¹
¹Imagerie par Résonance Magnétique Médicale et Multi-Modalités (UMR8081) IR4M, CNRS, Univ. Paris-Sud, Université Paris-Saclay, Orsay, France, ²Centre de Recherches Biologiques, CERB, Baugy, France, ³Centre d'Imagerie du Petit Animal CIPA, PHENOMIN-TAAM UPS44, CNRS, Orléans, France
- Asthma is a worldwide chronic respiratory disease. The common treatment by inhaled therapy needs quantitative imaging approaches to understand the impact of carrier gas on aerosol deposition. 3D UTE-MRI combined with aerosolized Gd-DOTA was applied onto spontaneous breathing and mechanically ventilated asthmatic animals. Here, administration and imaging protocols were developed to ventilate and nebulize control and asthmatic rats in order to compare the resulting aerosol distribution with two carrier gas mixtures: air and helium-oxygen.
-
- 4901 **Computer 32** [Evaluation of Regional Lung Function in Interstitial Lung Disease with Hyperpolarized Xenon-129 Lung 3D SB-CSI](#)

Jaime Mata¹, Kun Qing¹, Nicholas Tustison¹, Tallisa Altes^{1,2}, John Mugler¹, Michael Shim¹, Lucia Flors¹, Grady Miller¹, and Borna Mehrad¹

¹University of Virginia, Charlottesville, VA, United States, ²University of Missouri, MO, United States

3D Single-Breath Chemical Shift Imaging (3D SB-CSI) is capable of non-invasively assessing regional lung ventilation and gas uptake/exchange within a single breath-hold, typically less than 10 seconds. From this study, we present preliminary clinical results of 3D SB-CSI from healthy and interstitial lung disease (ILD) subjects. Having novel information on regional changes in ventilation and gas uptake/exchange allows for a better understanding of lung physiology, disease progression, and treatment efficacy.

Differentiation of thymic hyperplasia from thymic tumors with MR quantitative fat fraction technique in adulthood

Xiu-Long Feng¹, Yu-Chuan Hu¹, Lin-Feng Yan¹, Shi-jun Duan¹, Gang-Feng Li¹, Xiao-Cheng Wei², Guang-Bin Cui¹, and Wen Wang¹

¹Department of Radiology, Tangdu Hospital, Fourth Military Medical University, Xi'an, People's Republic of China, ²MR Research China, GE Healthcare China, Beijing, China

MRI estimated proton density fat fraction (MRI-PDFF) gives quantitative information of fat deposition in soft tissue. This study retrospectively evaluate the effectiveness of MRI-PDFF for distinguishing thymic hyperplasia from thymic tumors. As a conclusion, a significant higher mean fat fraction values were found in thymic hyperplasia compared to thymic tumors. MRI-PDFF technique could be used to differentiate thymic hyperplasia from thymic tumors before treatment.

Computer 34

Hyperpolarised 3He Diffusion-Weighted MRI in Mild Cystic Fibrosis Children and Age-matched Healthy Controls

Ho-Fung Chan¹, Guilhem J Collier¹, Laurie Smith^{1,2}, Helen Marshall¹, Juan Parra-Robles¹, Felix C Horn¹, Graham Norquay¹, Neil J Stewart¹, Chris J Taylor², Ina Aldag², Alex Horsley³, and Jim M Wild¹

¹Academic Unit of Radiology, University of Sheffield, Sheffield, United Kingdom, ²Sheffield Children's Hospital, Sheffield, United Kingdom, ³Manchester Adult CF Centre, Manchester, United Kingdom

Hyperpolarised gas MRI is sensitive to lung ventilation heterogeneity in early cystic fibrosis (CF) disease. However, lung microstructural changes that might accompany early lung disease in CF is less well explored. DW-MRI measurements were compared in mild CF children and age-matched healthy controls, and reassessed after a 2-year interval in the CF group. No significant difference in DW-MRI metrics (in contrast to changes in lung ventilation, VD%) was observed between healthy controls and CF children, and between baseline and 2-year follow-up visits. These results suggest that no acinar microstructural changes occur in early stage CF despite increases in ventilation heterogeneity.

Computer 35

Accelerated Stack-of-Spirals Breath-hold UTE Lung Imaging

John P. Mugler, III¹, Craig H Meyer², Josef Pfeuffer³, Alto Stemmer³, and Berthold Kiefer³

¹Radiology & Medical Imaging, University of Virginia, Charlottesville, VA, United States, ²Biomedical Engineering, University of Virginia, Charlottesville, VA, United States, ³Application Development, Siemens Healthcare, Erlangen, Germany

Stack-of-spirals and cones trajectories have been proposed to permit breath-hold ultrashort-echo-time (UTE) acquisitions of the human lung, although further acceleration would be valuable to permit improvements such as shorter breath-holds for respiratory comprised patients or higher spatial resolution. In this work, an accelerated UTE 3D stack-of-spirals pulse sequence was implemented using undersampled, dual-density spiral waveforms for acquisition and a SPIRiT-based algorithm for image reconstruction. Preliminary testing in healthy volunteers using 2-fold acceleration provided image quality comparable to that achieved with the original, unaccelerated pulse sequence.

Computer 36

4D and 2D phase-contrast MRI for the evaluation of pulmonary artery hemodynamics in patients with pulmonary hypertension and healthy volunteers

Malte Sieren¹, Clara Berlin¹, Thekla Helene Oechtering¹, Peter Hunold¹, Daniel Droemann², Joerg Barkhausen¹, and Alex Frydrychowicz¹

¹Clinic for Radiology and Nuclear Medicine, University Hospital Schleswig-Holstein, Lübeck, Germany, ²Medical Clinic III, Pulmonology, University Hospital Schleswig-Holstein, Lübeck, Germany

2D and 4D phase-contrast MRI (PC MRI) has been subject of recent studies to noninvasively diagnose pulmonary hypertension. The aim of this study was to compare values derived from both imaging techniques in a study collective consisting of healthy volunteers and patients with PH. Although 4D PC MRI generates higher quantitative values in comparison to 2D PC MRI, both sequences were able to distinguish volunteers from patients. In addition, 4D PC MRI visualized blood flow, underlining its additional value to detect secondary flow patterns in patients.

Ultra-fast balanced SSFP signal enhancement ratio mapping of the human lung parenchyma at 1.5T

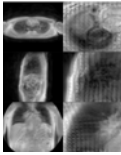

Orso Pusterla^{1,2}, Gregor Sommer³, Mark Wiese⁴, Didier Lardinois¹, Michael Tamm⁵, Jens Bremerich³, Francesco Santini^{1,2}, Grzegorz Bauman^{1,2}, and Oliver Bieri^{1,2}

¹Department of Radiology, Division of Radiological Physics, University of Basel Hospital, Basel, Switzerland, ²Department of Biomedical Engineering, University of Basel, Basel, Switzerland, ³Clinic of Radiology and Nuclear Medicine, Cardiac and Thoracic Imaging, University of Basel Hospital, Basel, Switzerland, ⁴Clinic of Thoracic Surgery, University of Basel Hospital, Basel, Switzerland, ⁵Clinic of Pneumology, University of Basel Hospital, Basel, Switzerland

In this work, we propose a new conceptual framework for functional pulmonary parenchyma imaging in the clinical setup from two volumetric ultra-fast balanced steady-state free precession (ufSSFP) breath-hold acquisitions before and after contrast agent administration. The resulting signal enhancement ratio (SER) maps of the parenchyma in patients shows similarity to SPECT/CT fusion images. The method requiring only two breath-hold acquisitions is rapid and amenable for clinical use.

- Spirometry provides global measures of lung function, whereas CT provides morphologic information but limited functional information. Current tests are limited in providing spatially resolved function of each lung separately. To address this need, we have developed a 4D ultra-short echo time MRI method where respiratory motion information is extracted directly from the acquired k-space data during normal and deep breathing maneuvers, and motion-resolved reconstruction is performed to extract spatially resolved functional information of each lung. Such a method will improve the ability to diagnose and manage Chronic Obstructive Pulmonary Disease, which is a major cause of death worldwide.

¹Institute for Diagnostic and Interventional Radiology, University Hospital Wuerzburg, Wuerzburg, Germany, ²Department of Pediatrics, University Hospital Wuerzburg, Wuerzburg, Germany
- The study's purpose was to assess the performance of Self-gated Non-Contrast-Enhanced Functional Lung (SENCEFUL)-MRI in detecting pulmonary perfusion deficits in patients with cystic fibrosis (CF). Nineteen patients with cystic fibrosis and 19 matched healthy controls underwent SENCEFUL-MRI at 1.5T. Four blinded readers rated perfusion and phase (i.e. temporal distribution of pulmonary blood flow) maps separately regarding local deficits followed by simultaneous assessment of both maps. Furthermore, phase data was plotted in histograms for objective comparison to the reader's results. SENCEFUL-MRI revealed statistically significant differences between CF-patients and controls. Furthermore, it demonstrated its potential in detection of pulmonary perfusion deficits.
-
- 4911 **Computer 42** [Detecting Differences in Parenchymal and Vascular Oxygenation in the Lungs with Quantitative Susceptibility Mapping](#)

- Quantitative susceptibility (QSM) mapping measures the spatial distribution of magnetic susceptibility, and is thus sensitive to the chemical and microstructure properties of tissues. Here we have combined QSM with multi-echo, radial ultra-short echo-time (UTE) MRI to assess regional variations in lung susceptibility in mice. We demonstrate QSM can differentiate between lung parenchyma, which is paramagnetic due to the presence of molecular O₂ and pulmonary vasculature which is diamagnetic. Moreover, we demonstrated that the susceptibility differences between these two lung regions increases with increased oxygen partial pressure, demonstrating the approach's sensitivity to regional pulmonary function.
-
- 4912 **Computer 43** [Quantification of regional lung ventilation in COPD patients: Validation of ventilation-weighted Fourier decomposition-MRI with dynamic fluorinated gas MRI and lung function testing.](#)
Till Frederik Kaireit^{1,2}, Marcel Gutberlet^{1,2}, Andreas Voskrebenev^{1,2}, Julia Freise³, Tobias Welte³, Frank Wacker^{1,2}, and Jens Vogel-Claussen^{1,2}

¹Institute of Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany, ²Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), German Center for Lung Research (DZL), Hannover, Germany, ³Clinic of Pneumology, Hannover Medical School, Hannover, Germany

Quantification of regional lung ventilation is of high relevance for lung diseases like chronic obstructive lung disease (COPD) or asthma. Regional ventilation of the lungs in COPD patients was assessed using ventilation-weighted Fourier decomposition-MRI and validated with real-time dynamic fluorinated MRI and lung function test. Strong correlations were found comparing both techniques with each other and with lung function testing which is used for COPD classification.

Computer 44

Development and comparison of ¹⁹F and hyperpolarized ¹²⁹Xe lung MRI for preclinical application in mice

Alexandre A Khrapitchev¹, Rohan S Virgincar^{1,2}, James R Larkin¹, Niloufar Zarghami¹, Sheena Wallington¹, Ana L Gomes¹, Stuart Gilchrist¹, Paul Kinchesh¹, Sean Smart¹, and Nicola R Sibson¹

¹CR-UK/MRC Oxford Institute for Radiation Oncology, Department of Oncology, University of Oxford, Oxford, United Kingdom, ²Biomedical Engineering, Duke University, Durham, NC, United States

The ¹⁹F approach is easier and cheaper to implement than the hyperpolarized gas setup and is immediately applicable to a range of pre-clinical work. However, ¹²⁹Xe MRI provides a unique dynamic tool that may have important applications warranting the additional effort and cost involved. We have compared lung ¹⁹F MRI with hyperpolarized ¹²⁹Xe MRI, in both cases using an Ultra Short Echo (UTE) sequence on a 7.0T preclinical spectrometer.

4914

Computer 45

Localized spectroscopy of hyperpolarized xenon-129 dissolved in the human head with a dedicated receiver array

Madhwesha Rao¹, Neil Stewart¹, Graham Norquay¹, Fraser Robb^{1,2}, and Jim Wild¹

¹University Of Sheffield, Sheffield, United Kingdom, ²GE Healthcare Inc, Aurora, OH, United States

This study investigates the spectral signal of hyperpolarized ¹²⁹Xe dissolved in the human head in vivo using a dedicated radiofrequency receiver coil array. With a 2.5-fold higher signal to noise ratio of the array compared to a conventional transmit-receive radiofrequency coil, we detected 8 spectral peaks compared to 5 peaks reported in an earlier study. From this, we postulate an individual assignment of spectral peaks for hyperpolarized ¹²⁹Xe dissolved in white matter and soft cartilaginous tissue, which were previously undistinguishable.

4915

Computer 46

3D mapping of alveolar oxygen partial pressure with hyperpolarized ¹²⁹Xe.

Iga Muradyan¹, Alan Hrovat², Mikayel Dabaghyan², and Samuel Patz¹

¹Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ²Mirtech, Inc., Brockton, MA, United States

Obtaining regional alveolar pO₂ is a coveted goal in pulmonary medicine, as it reflects both ventilation and perfusion. Hyperpolarized gases, mostly ³He were used to map p_AO₂. For ³He this is straightforward as helium is virtually insoluble in tissue. Xe, however, dissolves into tissue and blood and is carried away from the alveolar space, thus contributes to the loss of the ¹²⁹Xe MRI signal. To date no attempt has been made to address this issue. Here we report a novel use of SB-XTC to measure p_AO₂ in vivo while simultaneously measuring and taking into account xenon gas exchange on the signal decay.

4916

Computer 47

A Pipeline for Quantifying ¹²⁹Xe Gas Exchange MRI across Pulmonary Disorders

Ziyi Wang¹, Scott Haile Robertson², Jennifer Min Wang³, Mu He⁴, and Bastiaan Driehuis^{1,2,5}

¹Biomedical Engineering, Duke University, Durham, NC, United States, ²Medical Physics Graduate Program, Duke University, Durham, NC, United States, ³School of Medicine, Duke University, Durham, NC, United States, ⁴Electrical and Computer Engineering, Duke University, Durham, NC, United States, ⁵Radiology, Duke University Medical Center, Durham, NC, United States

With its solubility and abundant chemical shift in different tissues, hyperpolarized ¹²⁹Xe is uniquely suited to imaging pulmonary function. Previous efforts have demonstrated the ability to map gas transfer to interstitial barrier tissues and red blood cells (RBCs) using the gas-phase signal as a reference. Here, we extend this analysis by using a healthy reference cohort to establish relevant thresholds for quantitative display. With this methodology we now produce maps of ventilation, barrier uptake, and RBC transfer that demonstrate readily distinguishable patterns in a variety of obstructive, restrictive and vascular disorders.

Regional analysis of gas-uptake parameters in the lung using hyperpolarized ¹²⁹Xe chemical shift saturation recovery spectroscopy and dissolved-phase imaging: a reproducibility study

Agilo Luitger Kern^{1,2}, Marcel Gutberlet^{1,2}, Kun Qing³, Andreas Voskrebenezov^{1,2}, Filip Klimes^{1,2}, Till Kaireit^{1,2}, Christoph Czerner^{1,2}, Heike Biller^{2,4}, Frank Wacker^{1,2}, Kai Ruppert⁵, Jens Hohlfeld^{2,4}, and Jens Vogel-Claussen^{1,2}

¹Institute of Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany, ²Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), German Center for Lung Research (DZL), Hannover, Germany, ³Department of Radiology and Medical Imaging, University of Virginia, Charlottesville, VA, United States, ⁴Clinical Airway Research, Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany, ⁵Department of Radiology, University of Pennsylvania, Philadelphia, PA, United States

We performed a regional analysis of hyperpolarized ^{129}Xe gas-uptake parameters in the lung using localized chemical shift saturation recovery spectroscopy and dissolved-phase imaging with a three-point Dixon method for comparison. Localization of spectroscopic data acquired without spatial encoding was achieved using a 16-channel receive coil and Spectral Localization Achieved by Sensitivity Heterogeneity (SPLASH). The reproducibility of all parameters was studied and coefficients of variation are reported. Localized CSSR data exhibit evidence of gravitational effects in consistency with dissolved-phase imaging. The septal wall thickness derived from evaluation of CSSR data using the Patz model can be determined regionally with high reproducibility.

¹Radiology, Rakuwakai Otowa Hospital, Kyoto, Japan, ²Radiology, Stanford University School of Medicine, Stanford, CA, United States, ³Diagnostic Imaging and Nuclear Medicine, Kyoto University Hospital, Kyoto, Japan
- A recently developed ring-shaped PET scanner dedicated for breast (dbPET) provides high-resolution 3D images of a breast. We investigated the correlation between dbPET with ^{18}F -fluorodeoxyglucose and dynamic contrast MRI (DCE-MRI) findings in respect to breast background parenchyma and mass-forming breast cancers. Background parenchymal uptake on dbPET was not associated with background parenchymal enhancement on DCE-MRI. Tumor appearance on dbPET was similar to that on DCE-MRI in majority of cases, suggesting improved spatial resolution of dbPET as well as its feasibility for the use of the combined image analysis with DCE-MRI aiming at functional and structural assessment of primary breast tumors.

 Yiqi Hu¹, Tao Ai¹, Xu Yan², Dominik Nickel³, and Liming Xia¹
¹Radiology, Tongji Hospital, Wuhan, People's Republic of China, ²Siemens Healthcare, MR Collaboration NE Asia, People's Republic of China, ³Siemens Healthcare, MR Collaboration
- As the use of neoadjuvant chemotherapy is gradually increased in the treatment of breast cancer, evaluating its therapeutic effect is gaining importance. This study investigated the correlation between pharmacokinetic parameters using high spatial and temporal resolution dynamic contrast-enhanced MR imaging (DCE-MRI) and the prognostic factors for breast cancers. The results showed quantitative parameters (K_{trans}, k_{ep}) were significantly correlated to the prognostic factors (PR, Ki-67) of breast cancers. Quantitative parameters (K_{trans}, k_{ep}) of high spatial and temporal resolution DCE-MRI may be good indicators of therapeutic effect of patients undergoing neoadjuvant treatment.
-
- 4920 **Computer 75** **Breast Cancer and Body Adiposity by Breast MRI**
 Wenlian Zhu¹ and Dmitri Artemov^{1,2}
¹Division of Cancer Imaging Research, Department of Radiology, The Johns Hopkins University School of Medicine, BALTIMORE, MD, United States, ²Department of Oncology, The Sidney Kimmel Comprehensive Cancer Center, The Johns Hopkins University School of Medicine
- Using the thickness of the upper abdominal adipose layer measured from breast MRI as a surrogate body adiposity marker, this retrospective investigation validated a positive correlation between breast cancer and body adiposity in a cohort of 1616 breast MRI patients. Additionally, triple negative breast cancer was significantly associated with a younger age and higher body adiposity with respect to the hormone receptor positive breast cancer, while the hormone and HER-2 receptor positive (triple positive) type is only associated with a younger age. A trend of low body adiposity was observed in DCIS patients in the 30 – 49 age range.
-
- 4921 **Computer 76** **Effect of menstrual cycle on background parenchymal enhancement and the detectability of breast cancer by contrast-enhanced breast MRI: a multicenter study of an Asian population**
 Takeshi Kamitani¹, Hidetake Yabuuchi², Mitsuhiro Tozaki³, Yoshihide Kanemaki⁴, Satoshi Kawanami⁵, Koji Sagiyama¹, Yuzo Yamasaki¹, Seitaro Shin¹, and Hiroshi Honda¹
¹Department of Clinical Radiology, Kyushu University, Fukuoka, Japan, ²Department of Health Sciences, Kyushu University, Fukuoka, Japan, ³Department of Radiology, Sagara Hospital Affiliated Breast Center, Kagoshima, Japan, ⁴Breast and Imaging Center, St. Marianna University School of Medicine, Kawasaki, Japan, ⁵Department of Molecular Imaging & Diagnosis, Kyushu University, Fukuoka, Japan
- Background parenchymal enhancement (BPE) on breast contrast MRI is known to be associated with the menstrual cycle. We conducted a multicenter study to evaluate the effect of the menstrual cycle on BPE and cancer detectability by contrast-enhanced breast MRI in an Asian population. The Degrees of BPE and cancer detectability were assessed quantitatively and qualitatively. BPE were strongest in the proliferative phase. The detectability of breast cancer was better at the menstrual and proliferative phases than at secretory phase. Not only the proliferative phase but also the menstrual phase is suitable for breast MRI examinations of premenopausal Asian women.
-
- 4922 **Computer 77** **Early enhancement heterogeneity and density on ultrafast bilateral DCE-MRI may differentiate benign and malignant breast lesions**

Federico Pineda¹, Naoko Mori², Hiroyuki Abe¹, David Schacht¹, and Gregory Karczmar¹

¹Radiology, University of Chicago, Chicago, IL, United States, ²Tohoku University

Heterogeneity of enhancement has been shown to be a marker for malignancy in breast DCE-MRI, however standard dynamic protocols typically have low temporal resolution (60 to 90 seconds). Fast protocols have the advantage of accurately measuring early lesion kinetics. Heterogeneity of lesion enhancement in the first time-point (6 to 9 seconds) after arterial enhancement in the breast differed significantly between malignant and benign lesions; differences were not significant at later time-points.

Computer 78

High Resolution Breast Diffusion Weighted Imaging Using 2-D Navigated Multishot SENSE EPI with Image Reconstruction using Image-Space Sampling Function (IRIS) at 3 T

Habib Rahbar¹, Averi E Kitsch¹, Hans Peeters², Adrienne Kim¹, Tyson Nunn³, and Savannah C Partridge¹

¹Radiology, University of Washington, Seattle, WA, United States, ²Body/Oncology, Philips Healthcare, Best, Netherlands, ³Radiology, Seattle Cancer Care Alliance, Seattle, WA, United States

Conventional diffusion weighted (DW) MRI relies on a single-shot (SS) echo planar imaging (EPI) acquisition, which suffers from limited spatial resolution and detrimental geometric distortions. Multishot (MS) EPI techniques hold potential to improve the image quality and spatial resolution of DW MRI. We tested the feasibility and performance for breast imaging of a recently developed DW MS-EPI sequence incorporating a novel IRIS image reconstruction approach. Our initial results demonstrate this DW MS-EPI technique to provide robust high resolution breast DW images, with good image quality and reduced geometric distortion compared to conventional DW SS-EPI.

Intravoxel motion diffusion-weighted imaging and dynamic contrast-enhanced MRI of breast: comparison of perfusion-related parameters

Lei Jiang¹, Jiayin Gao², Zhuji Xu², Xu Lu², Dandan Zheng³, Yiming Zhou⁴, and Min Chen²

¹Beijing Hospital, Beijing, People's Republic of China, ²Beijing Hospital, ³GE Healthcare, ⁴Chaoyang Hospital

IVIM is a research and clinical focus in recent years. Whether its perfusion-related parameters are correlated with those obtained from DCE is still under debate. So the purpose is to investigate their correlation by performing both IVIM and DCE on 31 malignant and 35 benign lesions from 59 patients. Their diagnostic performance and correlation were investigated. No strong correlation was found between them, although their diagnostic performance is similar in terms of perfusion parameters. So IVIM is useful in lesion differentiation and potentially comparable with DCE-derived perfusion-related parameters. IVIM-derived perfusion-related parameters are probably a new entity of microcirculation parameters.

The Clinical Significance of Accompanying NME on Preoperative MR Imaging in Breast Cancer Patients

Hye Mi Gweon¹ and Eun Ju Son²

¹Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of, ²Gangnam Severance Hospital, Yonsei University College of Medicine

Our study evaluated the significance of accompanying NME in invasive breast cancer on preoperative MR imaging and assess the factors affecting the significance. We found that 24.5 % IDC with mass feature was accompanied by NME on preoperative MR imaging. Among them, 55 % accompanying NME had malignant pathologic results. Especially, HER2 positivity was significantly associated with malignant pathologic results of NME. Our results suggest that the accompanying NME should be carefully investigated on preoperative MR images and individually determined according to molecular subtypes.

Effect of Compressed Sensing Reconstruction Parameter on Ultrafast Dynamic Contrast Enhanced Breast MRI

Hajime Sagawa¹, Masako Kataoka¹, Shotaro Kanao², Natsuko Onishi², Maika Urago³, Marcel Dominik Nickelf⁴, Masakazu Toi⁵, Kyoji Higashimura¹, and Kaori Togashi²

¹Department of Radiology, Kyoto University Hospital, Kyoto, Japan, ²Department of Diagnostic Imaging and Nuclear Medicine, Kyoto University Graduate School of Medicine, Kyoto, Japan, ³Kyoto University Hospital, Kyoto, Japan, ⁴Siemens Healthcare GmbH, Erlangen, Germany, ⁵Department of Breast Surgery, Kyoto University Graduate School of Medicine, Kyoto, Japan

The aim of this study is to assess the impact of the number of iterations of CS reconstruction on kinetic parameters and the image similarity in DCE-MRI of the breast. Breast examinations include ultrafast DCE-MRI using CS were conducted for 21 patients. The images were reconstructed with different numbers of iterations, and the semi-quantitative and quantitative kinetics parameters were compared. The reconstructed images were evaluated by root mean square error (RMSE) and structural similarity (SSIM) as the quantitative image evaluation. In small number of iteration, the all kinetics parameters were underestimated especially in malignant lesion with hypervascularity.

Uniform flip angle 3D tailored excitation for MR breast imaging at 3T

Yi-Cheng Hsu^{1,2}, Sebastian Littin², Ying-Hua Chu^{1,2}, Fa-Hsuan Lin^{1,3}, and Maxim Zaitsev²

¹Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ²Medical Physics, Department of Radiology, University Medical Center Freiburg, Freiburg, Germany, ³Department of Neuroscience and Biomedical Engineering, Aalto University, Espoo, Finland

We proposed a two pulses excitation method using the linear gradients to achieve uniform 3D breast excitation. Different to previous studies, we don't need extra hardware and this method is applicable to all MRI systems. Compared to conventional excitation method, our method was able to achieve a more uniform flip angle (8.24% to 5.6%) and the mean flip angle difference between the left and the right breast was improved from 10.2% to 1.5%.

Computer 83

3T full breast diffusion imaging at sub-millimeter resolution with high immunity to artifacts

Eddy Solomon¹, Gilad Liberman¹, Noam Nissan², Edna Furman-Haran³, Miri Sklair-Levy⁴, and Lucio Frydman¹

¹chemical Physics, Weizmann Institute of Science, Rehovot, Israel, ²Radiology, Sheba-Medical-Center, ³Life Sciences Core Facilities, Weizmann Institute of Science, Rehovot, Israel, ⁴Sackler School of Medicine, Tel Aviv University

SPatio-temporal ENcoding (SPEN) MRI has been recently employed to quantify apparent diffusion coefficients in breast and in other challenging organs, thanks to its high immunity to B_0 -inhomogeneities and to chemical shift heterogeneities. In this study a new SPEN protocol is proposed combining multi-band pulses providing full coverage of both breasts with improved signal-noise-ratio, and multi-shot interleaved acquisitions achieving sub-millimeter spatial resolution. This provides a representation of the anatomical features that is similar to TSE, plus diffusion information containing insight into a lesion's nature. Validations and examples are shown at 3T, including healthy female volunteers and patients with breast malignancies.

Comparison of Radial and Cartesian Acquisitions in Breast MRI for Improved Visualization of the Axilla

Ping Ni Wang¹, Roberta M Strigel^{1,2,3}, Andre Fischer^{4,5}, Kang Wang⁶, Julia V Velikina¹, Frank Korosec², Ty A Cashen⁶, Kevin M Johnson¹, and James H Holmes²

¹Department of Medical Physics, University of Wisconsin Madison, Madison, WI, United States, ²Department of Radiology, University of Wisconsin Madison, Madison, WI, United States, ³Carbone Cancer Center, University of Wisconsin Madison, Madison, WI, United States, ⁴Cardiac Center of Excellence, GE Healthcare, Garching bei München, Germany, ⁵GE Global Research Europe, Garching bei München, Germany, ⁶Global MR Applications & Workflow, GE Healthcare, Madison, WI, United States

Dynamic contrast-enhanced (DCE) MRI is being increasingly used in the detection and diagnosis of breast cancer. Cartesian sampling is routinely used however ghosting artifacts caused by cardiac motion are a well known challenge that in some instances can severely obscure the gland tissue, axilla and even known cancer. Radial sampling has an intrinsic advantage for diminishing motion artifacts by averaging low special frequency signals through oversampling of central k-space data. In this study, we demonstrated the feasibility of using a 3D stack-of-stars radial acquisition to provide motion free images of the entire breast region including the axilla.

Diffusion Kurtosis as an in vivo Imaging Marker for Characterizing Breast Carcinoma: Correlation with Cellular Proliferation

Yao Huang¹, Yan Lin¹, Zhening Wang¹, Jiahao Liang¹, Renhua Wu¹, Weixun Lin², and Wei Hu³

¹Department of Radiology, 2nd Affiliated Hospital of Shantou University Medical College, China, Shantou, People's Republic of China, ²Department of General Surgery, 2nd Affiliated Hospital of Shantou University Medical College, China, Shantou, People's Republic of China, ³Department of Radiology, 1st Affiliated Hospital of Hubei Science and Technology College, Xianning Central Hospital, China, Xianning, People's Republic of China

This study aimed to assess the diagnostic accuracy of DKI technique in breast cancer patients, and to evaluate the potential associations between DKI-derived parameters and cellular proliferation of breast cancer. Mean kurtosis (MK) derived from DKI exhibited the maximal AUCs (0.972) and corresponding optimal sensitivity (90.2%) and specificity (95.2%) for distinguishing malignancy from benign lesions. Furthermore, positive correlation between MK and pathological prognostic factors (Ki-67 expression and histological grade) were found. Preliminary findings highlighted the potential utility of DKI as a sensitive MR sequence for imaging studies and diagnostic improvement of breast masses.

Serial Quantitative BPE measures on MRI: Correlation with 18F-FDG PET SUV measures in Normal Breast Tissue of Patients Undergoing Breast Cancer Therapy

Averi Kitsch^{1,2}, Habib Rahbar^{1,2}, Lanell Peterson^{3,4}, Jennifer Specht^{3,4}, and Savannah Partridge^{1,2}

¹Radiology, University of Washington, Seattle, WA, United States, ²Breast Imaging, Seattle Cancer Care Alliance, Seattle, WA, United States, ³University of Washington, Seattle, WA, United States, ⁴Seattle Cancer Care Alliance, Seattle, WA, United States

There is emerging data on the association of background parenchymal enhancement (BPE) on breast MRI with breast cancer risk. However, the underlying mechanism of BPE and its biologic relationship with cancer development remain unknown. Our study investigated the correlation of BPE with FDG PET standardized uptake values (SUV) in normal contralateral breast tissue of 35 women undergoing neoadjuvant chemotherapy. We found quantitative BPE area measures correlated with SUV metrics, and each decreased with therapy. Our findings suggest BPE reflects increased metabolic activity in normal breast tissue, which may provide valuable information for predicting cancer risk and response to therapy.

Comparison of Breast Pharmacokinetic Parameters in Fat-Water and Water Only Images

Philip K. Lee¹, Brian A. Hargreaves², Bruce L. Daniel², and Subashini Srinivasan²

¹Electrical Engineering, Stanford University, Stanford, CA, United States, ²Radiology, Stanford University, CA, United States

Pharmacokinetic parameters such as K^{trans} , k_{ep} , and v_e can be estimated from contrast enhanced breast MRI using Tofts model. Previous simulation has shown that K^{trans} has a maximum bias of 82% at 5s temporal resolutions in the presence of fat. In this work, we have compared the PK parameters estimated from in-phase fat-water, and water-only images in 7 malignant and 4 benign lesions. The presence of fat introduced biases in K^{trans} and k_{ep} respectively of -0.02 min^{-1} and 0.01 min^{-1} in malignant lesions and -0.001 min^{-1} and -0.003 min^{-1} in benign lesions, but did not affect the classification of lesions.

4934

Computer 89

Ultrafast Dynamic Contrast Enhanced MRI of the Breast Using Compressed Sensing: A Novel Technique for Separate Visualization of Breast Arteries and Veins in Very Early Phase

Natsuko Onishi¹, Masako Kataoka¹, Shotaro Kanao¹, Hajime Sagawa², Mami Iima¹, Rena Sakaguchi¹, Akane Ohashi¹, Ayami Ohno Kishimoto¹, Marcel Dominik Nickel³, Masakazu Toi⁴, and Kaori Togashi¹

¹Department of Diagnostic Imaging and Nuclear Medicine, Kyoto University Graduate School of Medicine, Kyoto, Japan, ²Division of Clinical Radiology Service, Kyoto University Hospital, Kyoto, Japan, ³MR Application Predevelopment, Siemens Healthcare GmbH, Erlangen, Germany, ⁴Department of Breast Surgery, Kyoto University Graduate School of Medicine, Kyoto, Japan

Ultrafast dynamic contrast enhanced (UF-DCE) MRI using compressed sensing enabled very fast scanning of the breast (every 3.7 sec/frame), and separately visualized breast arteries and veins. Breasts with cancers showed significantly shorter time intervals between arterial and venous visualization than the contralateral breasts without cancers. The time intervals in the breast with cancers tended to be shorter than those in the breasts with benign lesions. Shorter time intervals in breasts with cancers may reflect higher vascularity in malignancy. UF-DCE MRI has a potential to enable the differentiation of breast cancers in very early phase (0-60sec after contrast injection).

Computer 90

Automatic Breast Tumor Segmentation Methods for Mass and Non-mass Lesions for Quantitative Morphology and Texture Analysis
Xinxin Wang¹, Yang Zhang¹, Jeon-Hor Chen^{1,2}, Siwa Chan³, and Min-Ying Su¹

¹University of California, Irvine, Irvine, CA, United States, ²E-Da Hospital and I-Shou University, Kaohsiung, Taiwan, ³Tzu-Chi General Hospital, Taichung, Taiwan

A breast tumor segmentation platform for mass and non-mass tumors on 3D MRI was developed. The segmentation of non-mass lesions is challenging. We developed a new method based on region-growing with the threshold determined by comparison of the intensity histograms in an ROI containing suspicious tumor region vs. outside ROI containing normal fibroglandular tissues. Breast MRI of 122 patients with pathologically-confirmed breast cancer were studied. Of them, 14 had triple negative, 29 had HER2-positive, and 51 had Hormonal-positive, HER2-negative breast cancers. The segmented tumor ROI was analyzed to obtain morphology and texture parameters for differentiation of these 3 molecular subtypes.

Correction of image distortion and gradient nonlinearity in DTI of breast cancer

Lisa J Wilmes¹, Ek T Tan², Evelyn Proctor¹, Jessica Gibbs¹, Nola M Hylton¹, and David C Newitt¹

¹Radiology and Biomedical Imaging, University of California San Francisco, San Francisco, CA, United States, ²GE Global Research, Niskayuna, NY

The individual and combined effects of correction for susceptibility-induced distortion, distortion due to eddy currents, and bias from gradient non-linearity on breast DTI metrics were evaluated. Using an ice-water phantom we found that the correction of gradient nonlinearity resulted in strong bias reduction, while the distortion correction provided further reduction of bias and variance. The effects of these corrections were quantified in 12 subjects with malignant breast tumors and found to parallel the effects measured in the phantom.

4937

Locally altered lipid profiles: a hallmark of breast cancer metabolism?

Ileana Hancu¹, Christopher Sevinsky¹, Beatrice Andre², Fiona Ginty¹, Elizabeth Morris², and Sunitha Thakur²

¹GE Global Research Center, Niskayuna, NY, United States, ²Memorial Sloan Kettering Cancer Center, New York City, NY, United States

Cancer cells are known to produce their own fatty acids (FA's) and co-opt local fat reserves for energy/cell division needs. In this study, single-voxel MRS data were used to assess the spatial/spectral lipid profiles of normal volunteers and subjects with suspicious lesions. Statistically different lipid profiles were found in tumors than in the contralateral breast of cancer patients; the latter were similar to lipid profiles of normal volunteers. Fibrocystic epithelial/breast cancer cell NMR experiments confirmed differential FA composition/uptake for the two cell types. MRI/MRS-based profiling of lipid metabolism may provide a unique tool for better breast cancer tumor detection/characterization.

Enabling high resolution MRE images of the breast

Stefan Heinz Hoelzl¹, Sweta Sethi², Jelizaveta Sudakova¹, Ayse Sila Dokumaci¹, Jurgen Henk Runge¹, Tony Ng³, Arnie Purushotham⁴, and Ralph Sinkus¹

¹Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, ²Department of Research Oncology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ³Division of Cancer Studies, King's College London, London, United Kingdom, ⁴Department of Imaging Chemistry and Biology, King's College London, London, United Kingdom

Achieving high-resolution MR-Elastography images of the breast is a challenge due to shear wave attenuation and shadowing effects in breast tissue resulting in loss of wave energy and hence poor signal to noise ratio. We present a novel breast transducer set-up to ensure complete wave penetration throughout the entire breast. Waves reach even far upwards to enable quantification of axillary lymph nodes. Mechanical vibrations are generated via a novel concept utilizing an eccentric rotor that yields inherently constant amplitude with driving frequency. Volunteer results of wave speed and attenuation at 2mm isotropic resolution are presented including the axilla region.

The detectability of mammary lesions dependent on the patients' arm position and breathing style during a liver study

Yasuo Takasu^{1,2}, Yuko Shimada¹, Tosiaki Miyati², and Toshiki Shiozaki¹

¹Osaka Red Cross Hospital, Osaka, Japan, ²Division of Health Sciences, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, Japan

This study aimed to evaluate whether the incidental finding of the mammary lesions was influenced by the patient's arm position and respiration style during liver magnetic resonance imaging (MRI). If the mammary lesion was detected earlier, treatment could be performed earlier. Therefore, the finding of mammary lesion during liver studies was useful information. The incidental detection of mammary lesions was influenced by the patient's arm position and breathing style. Unexpected mammary lesions could be detected when the arms were positioned at the sides of the body and the exhalation style was used during liver MRI.

Co-registration of Breast MRI and CT Using Gravity Unloading

Yang Zhang¹, Jeon-Hor Chen^{1,2}, Siwa Chan³, and Min-Ying Su¹

¹Tu & Yuen Center for Functional Onco-Imaging, University of California, Irvine, Irvine, CA, United States, ²E-Da Hospital and I-Shou University, Kaohsiung, Taiwan, ³Tzu-Chi General Hospital, Taichung, Taiwan

A biomechanical simulation method for co-registration of breast MRI and low-dose chest computed tomography (LDCT) images is presented, by aligning the images in a virtually unloaded configuration. The breast tissue was considered as neo-Hookean material, and the finite element method was applied to simulate the deformation from gravity-unloading. The Demon's non-rigid registration algorithm was applied to co-register the gravity-unloaded MRI and LDCT models. Fourteen normal subjects who received both breast MRI and LDCT for breast and lung cancer screening were analyzed. The results show that the pre-processing using gravity unloading can facilitate the co-registration of LDCT and MRI.

Development of Robust Texture Parameters for Characterizing Normal Breast Parenchymal Patterns

Yang Zhang¹, Jeon-Hor Chen^{1,2}, Siwa Chan³, Dah-Cherng Yeh⁴, and Min-Ying Su¹

¹Tu & Yuen Center for Functional Onco-Imaging, University of California, Irvine, Irvine, CA, United States, ²E-Da Hospital and I-Shou University, ³Tzu-Chi General Hospital, Taichung, Taiwan, ⁴Taichung Veterans General Hospital, Taichung, Taiwan

The non-fat-sat T1-weighted breast MRI of 57 normal healthy women were analyzed. In order to test the robustness of parameters we compared the texture analyzed from the ROI's of different sizes as the largest cuboid that can fit within the breast and cover 30%, 40%, and 50% of fibroglandular tissue slices. 21 texture features were selected as robust features that were not greatly affected by the cuboid ROI size. The concordance correlation coefficient of the percent density between bilateral breasts was very high, 0.98. Of all texture parameters, "Information Measure for Correlation (IMC)" and "Contrast" show the highest ccc, 0.90-0.98.

Investigating the role of DCE-MRI, over T2 and DWI, in accurate PIRADS-v2 assessment of clinically significant peripheral zone prostate lesions, as defined at radical prostatectomy

Mehdi Taghipour¹, Elmira Hassanzadeh¹, Francesco Alessandrino², Mukesh Harisinghani³, Clare M.C Tempamy¹, and Fiona M Fennessy^{1,2}

¹Radiology, Harvard Medical School, Brigham and Women's Hospital, BOSTON, MA, United States, ²Imaging, Dana-Farber Cancer Institute, Boston, MA, United States, ³Radiology, Harvard Medical School, Massachusetts General Hospital, Boston, MA, United States

DCE has a secondary role in detecting peripheral zone lesions using PIRADS v2 and is limited to PZ lesion with DWI score of 3. The goals of this study are to determine the frequency with which DCE plays a role changing the final PI-RADS assessment score for PZ lesions, and 2) determine the accuracy of DCE-MRI in upgrading the assessment score. 271 patients with biopsy proven prostate cancer diagnosis, a mp-MRI, and who underwent curative radical prostatectomy were included in the study. DCE played a role only in 16.6% (45/271) of patients and showed sensitivity of 63.8% in upgrading lesions. In conclusion, the added value of DCE to T2-WI and DWI is very limited in diagnosis of csPC.

Low-To-High b-Value DWI Ratio Image in Multiparametric MRI of the Prostate: Feasibility, Optimal Combination of b-Values, and Comparison with ADC Maps for the Detection of Prostate Cancer

Franklin Olumba¹, Parker Lawson¹, Alexander Liu¹, Robert E. Lenkinski¹, Qing Yuan¹, Ivan Pedrosa¹, Gaurav Khatri¹, Takeshi Yokoo¹, Daniel Costa¹, and Yin Xi¹

¹Radiology, UT Southwestern Medical Center, Dallas, TX, United States

This study demonstrated the feasibility of generating a DWI-based image that compares the signal intensity on low versus high b-values (DWI_{ratio} image) and compared this model-independent approach to the conventional ADC map in terms of quantitative relative contrast (RC) in signal intensity between lesion and normal tissues and subjective assessment of artifacts, lesion conspicuity, and overall image quality by blinded radiologists. The DWI_{ratio} images showed significantly higher RD and lower artifacts and non-inferiority in lesion conspicuity and overall image quality. The model-independent nature of this approach has the potential to improve inter-subject and inter-vendor reproducibility of DWI data for the detection of prostate cancer when compared to ADC maps.

Mapping prostatic microscopic anisotropy using linear and spherical b-tensor encoding: A preliminary study

Markus Nilsson¹, Filip Szczepankiewicz², Mikael Skorpil^{3,4}, Carl-Fredrik Westin⁵, Lennart Blomqvist^{3,4,6,7}, and Fredrik Jäderling^{6,7}

¹Clinical Science, Radiology, Lund University, Lund, Sweden, ²Clinical Sciences Lund, Medical Radiation Physics, Lund University, Lund, Sweden, ³Department of Radiology, Uppsala University, Uppsala, Sweden, ⁴Department of Radiation Sciences, Umeå University, Umeå, Sweden, ⁵Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, ⁶Department of Molecular Medicine and Surgery, Karolinska Institute, Stockholm, Sweden, ⁷Department of Diagnostic Radiology, Karolinska University Hospital, Solna, Sweden

Diffusion tensor imaging (DTI) has the potential to improve prostate cancer detection, since anisotropy is expected to correlate with tumor aggressiveness and differentiation. Differences in fractional anisotropy between cancer and normal tissue have been observed, although data is somewhat contradictory. A problem with DTI is its inability to distinguish low anisotropy from high orientation dispersion. In this study, we map the anisotropy independent of orientation in the prostate, by the use of a novel diffusion-encoding technique that permits encodings with variable b-tensor shapes. The microscopic anisotropy was found to be generally higher in cancer than in normal prostatic tissue.

Inverse Laplace transform analysis using a fast multi-echo TSE sequence for prostate cancer diagnosis

Shiyang Wang¹, Harsh Agrawal², Milica Medved¹, Tatjana Antic³, Ambereen Yousof¹, Gregory Karczmar¹, Roger Bourne⁴, and Aytok Oto¹

¹Radiology, University of Chicago, Chicago, IL, United States, ²R&D Institute, Samsung R&D Institute, Bangalore, India, ³Pathology, University of Chicago, Chicago, IL, United States, ⁴Health Science, University of Sydney, Sydney, Australia

To evaluate the inverse Laplace model fitting to multiple TE TSE data for prostate cancer diagnosis. Prostate tissue has glandular structure with luminal volume and epithelial cells forming the walls of gland. The underlying physical phenomenon in prostate cancer can be accurately captured using two-compartment T2 decay modeling. It is impossible to acquire MR images to perform accurate multi-compartment T2 decay model in clinically feasible scan times since multiple T2W MRI images over a wide range of echo times are required. Recently a fast multi-echo TSE (ME-TSE) T2 mapping technique, k-t-T2 MRI was developed to obtain high resolution T2 maps in clinically feasible scan time. In this study, a new implementation of the inverse Laplace transform was applied to the multi-echo TSE T2WI data. We present evidence that multiple slow components can be present in the decaying T2WI signal in the normal tissue in the prostate but were absent in pathology confirmed cancers on k-t-T2 data.

Diagnostic Performance in MR-visible Prostate Cancer: Can a Quantitative Computer-aided Diagnosis System Be Superior to the Qualitative PI-RADS v2 Guideline?

Jing Wang¹, Yang Fan², and Yudong Zhang³

¹Center for Medical Device Evaluation, CFDA, Beijing, People's Republic of China, ²MR Research China, GE Healthcare, Beijing, People's Republic of China, ³Department of Radiology, the First Affiliated Hospital with Nanjing Medical University, Nanjing, People's Republic of China

A novel CAD system was developed for prostate cancer detection based on multi-parametric MRI, including textured T2w, DKI and Tofts-Ktrans. MR features were evaluated by using machine-assisted classification methods such as PCA and SVM analysis. The validation performed in 54 patients confirmed as PCa, to determine whether the CAD has the ability to correct diagnosis in MR-visible prostate cancer, as comparison with a proposed structured PI-RADS v2. Our results showed that the automatic PCa detection using CAD had significantly higher AUC than PI-RADS v2 in distinguishing cancer from normal prostate tissue.

Impact of Temporal Resolution on Quantitative DCE-DISCO Measurements in Prostate Cancer

James A Rioux^{1,2,3}, Peter M Lakner^{1,4}, Steve Patterson¹, Mark Parker^{1,5}, Jennifer Merrimen⁶, Cheng Wang⁶, Chris V Bowen^{1,2,3}, and Sharon Clarke^{1,2,3}

¹Biomedical Translational Imaging Centre (BIOTIC), Nova Scotia Health Authority, Halifax, NS, Canada, ²Diagnostic Radiology, Dalhousie University, Halifax, NS, Canada, ³Physics and Atmospheric Science, Dalhousie University, Halifax, NS, Canada, ⁴Computer Science, Dalhousie University, Halifax, NS, Canada, ⁵School of Health Sciences, Dalhousie University, Halifax, NS, Canada, ⁶Pathology, Dalhousie University, Halifax, NS, Canada

Depending on the particular application, the temporal resolution of dynamic contrast-enhanced MRI may have an impact on measurements of quantitative parameters related to contrast agent kinetics. In this study we retrospectively altered the temporal resolution of DCE-DISCO acquisitions in patients with prostate cancer, and examined the effect on the rate constant K^{trans} in both normal tissue and cancer (as confirmed by histopathology). The difference in mean K^{trans} values between tissue types was found to vary significantly with temporal resolution between 4 and 10s, suggesting that the uptake dynamics in cancer are more accurately sampled at higher temporal resolution.

A New Multi-Atlas Selection Strategy for Zone Segmentation of the Prostate

Michela Antonelli¹, Edward W Johnston², Manuel Jorge Cardoso¹, Benoit Presles¹, Shonit Punwani^{1,2}, and Sebastien Ourselin^{1,3}

¹Translational Imaging Group, CMIC, University College London, London, United Kingdom, ²Academic Radiology, University College London Centre for Medical Imaging, London, UK, ³Dementia Research Centre, Department of Neurodegenerative Disease, UCL Institute of Neurology, London, UK

Automatic segmentation of the prostate into peripheral and transition zones is paramount in developing computer aided diagnosis systems for prostate cancer diagnosis, as cancer behaves differently in each zone. We propose a multi-atlas based segmentation (MAS) algorithm characterized by a new atlas selection strategy: the performance of a subset of atlases is evaluated considering how well that subset segments the image that is most similar to the target image. Comparison of our method with three other MAS algorithms on fifty-five patients shows a statistically significant improvement on the segmentation accuracy.

Contribution of Radiomics Features from DCE-MRI and DWI in Differentiating Benign from Malignant Lesions in Suspicious Breast (MRI BI-RADS Category 4) Findings

Bin Hu¹, Lina Zhang², Ke Xv², Shu Li², Songbai Li², Ning Huang³, and Yan Guo³

¹First Affiliated hospital of China Medical University, Shenyang, People's Republic of China, ²First Affiliated hospital of China Medical University, ³GE Healthcare, Lifescience, China

We aimed to find a promising tool to improve the diagnostic efficiency of suspicious breast lesions classified in BI-RADS Category 4 from malignant lesions in order to avoid unnecessary biopsy, surgery, even psychological pressure. 33 patients (all female, 27y-82y) were included in our retrospective study and all underwent pre-operative breast DCE-MRI and DWI using a 3.0T MRI (SIEMENS Magntom Verio 3.0T). The radiomics features were acquired by Omni-Kinetics software (GE Healthcare). Non-parametric test and ROC curve were used in statistical analysis. The results implied that the radiomics parameters, especially skewness, kurtosis, IDM and inertia in Ktrans and ADC had great potential.

Prostate cancer detection with multiparametric MRI based computer-aided diagnosis: which sequence is the dominant technique

Ge Gao¹, Xiaoying Wang, Chengyan Wang, and Jue Zhang

¹Radiology, Peking University First Hospital, Beijing, People's Republic of China

Differ from PI-RADS v1, the updated PI-RADS v2 offers a decision process that puts the sequences as different role in scoring process and results in a final five-point score. However, the efficiency of each sequence in prostate cancer (PCa) detection in peripheral zone (PZ) and transition zone (TZ) is investigated by radiologists reading test preliminarily, which is highly depends on reader's expertise and experience. This work applied a previous published machine learning model to investigate the weight of different sequences, including T2WI, DWI/ADC and DCE, in clinical significant PCa detection, and found that DWI/ADC performed the best both in PZ and TZ clinical significant PCa detection among these basic sequences which is recommended by PI-RADS v2

Poor enhancement of colorectal liver metastases on delayed phase gadobutrol enhanced MRI may be related to increased number of APC mutations

Helen Cheung¹, Arun Seth², Yutaka Amemiya², Eugene Hsieh³, Paul Karanicolos³, Natalie Coburn³, Xiaoyang Liu³, Vikrum Seth², Calvin Law³, and Laurent Milot¹

¹Medical Imaging, Sunnybrook Health Sciences Centre, University of Toronto, Toronto, ON, Canada, ²Sunnybrook Research Institute, ³Sunnybrook Health Sciences Centre

We recently demonstrated that delayed enhancement of colorectal liver metastases (CRLM) on gadobutrol-enhanced MRI is associated with long-term survival. We performed a hypothesis-generating pilot study to determine whether delayed enhancement on MRI is related to the number and types of genetic mutations. There were a greater number of somatic APC mutations in hypoenhancing tumors compared to isoenhancing tumors or hyperenhancing tumors (N=15, p=0.013). There was no difference in the number of germline mutations or number of overall somatic mutations among MRI groups. Poor enhancement of CRLM on delayed phase gadobutrol-enhanced MRI may correlate with increasing number of somatic APC mutations.

Rectal perfusion parameters normalized to tumour free rectal wall can predict complete pathological response to neoadjuvant chemoradiotherapy.

Sonal Krishan¹ and Anirudh Kohli²

¹Radiology, Medanta Hospital Gurgaon, Gurgaon, India, ²Radiology, Medanta Hospital, India

The aim of this study was to evaluate absolute and normalized change in qualitative and semi quantitative perfusion parameters in predicting complete pathological response to CRT. Perfusion parameters of Pre and post treatment imaging of histopathologically proven 10 patients with rectal cancer who had complete response and complete absence of tumour on histopathology following complete treatment (Group 1) were compared with 10 patients with residual tumour on histopathology following treatment (Group 2). The two groups were matched for T stage of tumour. Semiquantitative perfusion MRI parameters (Ktrans, Kep, Ve, IAUC; Toft model) were quantified by manually delineating a region of interest in the upper, mid and lower third of tumour at least 1cm square, in addition similar parameters were obtained from the normal rectal wall atleast 1cm away from the potential resection margin, absolute as well as values normalized values to the perfusion in the normal rectal wall were evaluated. Qualitative perfusion parameters were also assessed (wash in, wash out, TTP, AT, PEI, IAUC). After CRT, all patients underwent complete surgical resection and the surgical specimen served as the gold standard. Difference in absolute and normalized qualitative parameters were compared within each group using paired t-test and between each group using ANOVA. Washin, Washout, PEI, Ktrans, IAUC in the complete pathological responders when normalized to the adjacent normal rectal wall showed ratio's approaching near 1 suggesting that rectal perfusion returns similar to the adjacent normal rectal wall in complete pathological responders. The difference in the normalized values in the responders and non responders was statistically significant. Within group change in absolute mean values in the responders and non responders was not statistically significant. Perfusion parameters can be used in predicting response to treatment, when normalised to the adjacent normal rectal wall.

Differentiation of low- and high- grade hepatocellular carcinomas with texture features and a machine learning model in arterial phase of contrast-enhanced MR

Wu Zhou¹, Qiyao Wang¹, Guangyi Wang², Zaiyi Liu², Changhong Liang², and Lijuan Zhang¹

¹Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, People's Republic of China, ²Department of Radiology, Guangdong General Hospital, Guangdong Academy of Medical Sciences

Texture has been a recognized feature for biological aggressiveness of hepatocellular carcinomas (HCCs). However, texture feature alone may not be optimal to characterize malignancy of HCC. Computer-aided techniques combined with multi-feature fusion may be a method of choice for the preoperative assessment of the aggressiveness of HCC. To this end, a computer-aided method in the combination with machine learning technique based on texture analysis for malignancy differentiation of HCCs was demonstrated and high classification performance (AUC>0.9) of the classifier was achieved to differentiate low- and high- grade of HCCs.

Quantitative dynamic contrast enhanced magnetic resonance imaging of hepatocellular carcinoma: A prospective self-control study between single and dual input arterial function

Meiling Li¹, Jian Lu¹, Hongwei Liang¹, Jifeng Jiang¹, and Peng Cao²

¹Department of Radiology, Nantong Third People's Hospital, Nantong University, Nantong, People's Republic of China, ²GE healthcare, Shanghai, People's Republic of China

This prospective self-control study was designed to explore if there is difference between single and dual arterial input function (AIF) for analyzing quantitative dynamic contrast enhanced magnetic resonance imaging (DCE-MRI) of hepatocellular carcinoma (HCC). Our result showed that there is no statistical difference of quantitative parameters K^{trans} , V_e , V_p between single and dual AIF groups. The parameter K_{ep} was different between two groups, but it had a parallel relationship with CD34-MVD of HCC, for that, dual AIF didn't have advantage over single AIF.

A New System to Spatially Align In Vivo MRI, Ex Vivo MRI, and Whole-Mount Histopathology Slides for Integrated Prostate Cancer Research

Holden H Wu^{1,2}, Steven Raman¹, Pooria Khoshnoodi¹, Alan Priester², Kyunghyun Sung^{1,2}, Daniel Margolis^{1,3}, Preeti Ahuja¹, Anthony Sisk⁴, Jiati Huang^{4,5}, Robert Reiter⁶, and Dieter Enzmann¹

¹Radiological Sciences, UCLA, Los Angeles, CA, United States, ²Bioengineering, UCLA, Los Angeles, CA, United States, ³Radiology, Cornell University, New York, NY, United States, ⁴Pathology, UCLA, Los Angeles, CA, United States, ⁵Pathology, Duke University, Durham, NC, United States, ⁶Urology, UCLA, Los Angeles, CA, United States

Multi-parametric MRI is an indispensable tool for prostate cancer (CaP) management and spatial alignment of in vivo MRI to histopathology is critical for its development. In addition, ex vivo MRI has distinct advantages for investigating ultrahigh-resolution MRI and quantitative MRI of CaP. In this work, we propose a new system for spatial alignment of in vivo MRI, ex vivo MRI, and whole-mount histopathology slides. Results from a pilot study of CaP patients demonstrate successful integration with the clinical workflow and good spatial alignment of the image sets. This new system may enable novel research of CaP biomarkers and predictive models.

Comparison of Radiologist Perception of Image Quality of Advanced Diffusion vs. RESOLVE Diffusion

Bonnie N. Joe¹, Kimberly Ray¹, Amie Lee¹, Vignesh Arasu¹, Lisa Wilmes¹, Vibhas Deshpande², Sinyeob Ahn², and Nola Hylton¹

¹Radiology and Biomedical Imaging, UCSF, San Francisco, CA, United States, ²Siemens Medical Solutions

In order to gain acceptance of DWI in the clinical setting, consistent high image quality with minimal breast distortion is required. Although time of acquisition is slightly longer for the RESOLVE compared with the advanced diffusion sequence, the benefits of improved image quality, particularly with respect to image distortion and phase ghosting are preferred by clinical breast imaging radiologists based on this reader study. The theoretical benefits of using readout-segmented diffusion imaging technique in RESOLVE to improve image quality can be realized in a routine clinical practice.

4963

Spatially-sensitive model for detection of prostate cancer on multiparametric MRI

Ethan Leng¹, Jin Jin², Lin Zhang², Christopher A. Warlick³, Benjamin Spilseth⁴, Joseph S. Koopmeiners², and Gregory J. Metzger¹

¹Center for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN, United States, ²Division of Biostatistics, School of Public Health, University of Minnesota, Minneapolis, MN, ³Department of Urologic Surgery, Institute of Prostate and Urologic Cancers, University of Minnesota, Minneapolis, MN, United States, ⁴Department of Radiology, University of Minnesota, Minneapolis, MN, United States

A novel predictive model of prostate cancer (PCa) on multiparametric MRI was developed that takes into account the spatial distribution of PCa within the prostate and the spatially-autocorrelated nature of mpMRI data. The performance of the proposed model was compared to the LASSO-based model we previously described on 34 PCa cases using both voxel-wise metrics (AUC) and slice-wise metrics (\$\$\$s_s\$\$\$) we recently developed. The proposed model achieved superior predictive performance both in terms of AUC (0.81 vs 0.77) and \$\$\$s_s\$\$\$ (0.45 vs. 0.35) over the 34 cases, with significant improvements for the majority of cases.

4964

Computer 119

Texture analysis of prostate MRI by using the Gray-Level Co-Occurrence Matrix (GLCM) for the characterization of prostate cancer, normal prostatic peripheral zone, and transition zone

Sung Kyoung Moon¹, Hyug-Gi Kim², Kyung Mi Lee¹, and Joo Won Lim¹

¹Radiology, Kyung Hee University Hospital, College of Medicine, Kyung Hee University, Seoul, Korea, Republic of, ²Biomedical Engineering, College of Electronic Information Engineering, Kyung Hee University, Korea, Republic of

GLCM is a mathematical method that extracts the various quantitative parameters representing texture features of the images. Our hypothesis is that the texture analysis of prostate MRI can be an additional problem-solving tool in differentiating cancer and normal prostate tissue. The texture parameters of ROIs in prostate cancer, normal peripheral zone, and normal transitional zone in T2WI were extracted and compared statistically in 20 prostate cancer patients. The correlation, energy, and maximum probability in prostate cancer and peripheral zone are significantly different. The texture analysis can be used for the characterization and differentiation of prostate cancer and normal prostate tissue.

Computer 120

To quantitatively investigate the contrast ratio of prostate cancer of computed high diffusion-weighted imaging (DWI) from DWIs acquired from lower b-values and correlation to tumour aggressiveness

RAYMOND LEE¹, Gladys Lo¹, and Ka Fat John Chan¹

¹DEPARTMENT OF DIAGNOSTIC & INTERVENTIONAL RADIOLOGY, HONG KONG SANATORIUM & HOSPITAL, HONG KONG, Hong Kong

Apparent Diffusion Coefficient (ADC) maps obtained diffusion weighted imaging (DWI) have been shown to detect prostate cancer (PCa) and also correlate with tumor aggressiveness. Recent studies showed that improve detection of prostate cancer by high b-value DWI. However, high b-value images have an inherently low signal-to-noise ratio (SNR) and are prone to increased susceptibility artefact. Computed DWI (cDWI) is a method capable of obtaining high b-value images, which avoids the technical challenges of actually measuring them. Previous studies with limited sample size have evaluated the cDWI with high b-value but results were not conclusive. Current study may give an insight whether high b-value cDWI is valuable for differentiation of high risk versus low risk PCa.

Imbalance in dietary intake and energy expenditure are associated with obesity, diabetes and metabolic disorders. Adipocyte size and expansion of adipose tissue plays a critical role towards the progression of diet induced obesity. Brown adipose tissue (BAT) plays a critical role in modulating different fat depots in the body. BAT can be functionally activated by administering the β 3-adrenergic agonist. Understanding the mechanisms associated with BAT activation and the possibility of reversing insulin resistance and its impact on whole body metabolism is of current clinical interest for combating diabetes. In the current study, we investigated the fat partitioning in high fat diet induced obese rodent model by β -adrenergic-mediated BAT activation.

Analysis of motility in apparently normal small bowel – relationship to Crohn's symptoms

Ruaridh M Gollifer¹, Alex Menys¹, Jessica Makanyanga¹, Carl A, J Puylaert², Frans M Vos^{2,3}, Jaap Stoker², David Atkinson¹, and Stuart A Taylor¹

¹Centre for Medical Imaging, University College London (UCL), London, United Kingdom, ²Department of Radiology, Academic Medical Center (AMC), Amsterdam, Netherlands, ³Quantitative Imaging Group, Delft University of Technology, Delft, Netherlands

Crohn's disease (CD) patients often suffer abdominal symptoms even when their disease is apparently in remission with no identifiable active inflammation.¹ Ongoing aberrant gut motility has been postulated as a cause, and this can now be quantified using MRI.² This study tested the association between abdominal symptoms based on the Harvey-Bradshaw Index (HBI) and MRI derived motility metrics in morphologically healthy small bowel in CD patients. An inverse association was found between reduced motility spatial variation across the small bowel and symptoms, particularly diarrhoea. This association was strongest when HBI scores were higher.

Feasibility of Performing Dynamic and Delayed Enhancement and Magnetization Transfer Ratios in pediatric patients undergoing clinically-indicated MRE: pilot study to assess image quality for quantitative evaluation

Mary-Louise Catherine Greer^{1,2}, Susan Shelmerdine³, Kedar Patil^{1,2}, Claire Cuscaden⁴, Debra Drossman¹, and Logi Vidarsson¹

¹Department of Diagnostic Imaging, The Hospital for Sick Children, Toronto, ON, Canada, ²Department of Medical Imaging, University of Toronto, Toronto, ON, Canada, ³Department of Radiology, Great Ormond Street Hospital, London, United Kingdom, ⁴Department of Radiology, The Royal Brisbane and Women's Hospital, Brisbane, Australia

Purpose: Assess feasibility of applying magnetization transfer (MT) and dynamic and delayed enhancement (DCE) sequences during MR Enterography(MRE) in children.

Methods: REB approved, in this prospective study, patients \leq 18 years undergoing MRE for suspected or proven inflammatory bowel disease were consented for application of MT and DCE sequenced in addition to standard clinical sequences. These were assessed and prospectively recruited and imaging sequences applied. Imaging was subjectively analysed by two radiologists or a radiologist and physicist in the first arm by consensus for sequence modification.

Results: Inter and intra-reader analysis was undertaken.

Conclusion: DCE is robust, MTR requires further modification.

Magnetization transfer MRI for evaluating bowel fibrosis and inflammation in patients with stricturing Crohn's disease

Xuehua Li¹, Zhuangnian Fang¹, Siyun Huang¹, Li Huang¹, Zhongwei Zhang², Xu Yan³, Xiaolei Zhu⁴, Jinjiang Lin¹, Mengchen Zhang¹, Mengjie Jiang¹, Shiting Feng¹, Canhui Sun¹, and Ziping Li¹

¹Department of Radiology, The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, People's Republic of China, ²Department of Biomedical Engineering, Cancer Biology and Radiology, Wake Forest School of Medicine, NC, United States, ³MR Collaboration NE Asia, Siemens Healthcare, Shanghai, People's Republic of China, ⁴MR Scientific Marketing NE Asia, Siemens Healthcare, Guangzhou, People's Republic of China

This study aimed to assess the efficacy of Magnetization Transfer MRI (MTI) for evaluating bowel fibrosis and inflammation in patients with stricturing Crohn's Disease (CD). Bowel wall MTR with normalization to skeletal muscle was calculated and correlated to histologic fibrosis and inflammation as well as amount of type I collagen and vessel density. The results showed that normalized MTRs correlated with histologic fibrosis and type I collagen scores, but did not correlate with inflammation scores or vessel densities. Thus, MTI can accurately detect and distinguish varying degrees of bowel fibrosis with or without coexisting inflammation in human CD.

Comparison of Measurement of Abdominal Visceral Adipose Tissue in Men and Women by MRI vs. DXA

Cherie R Shook¹, Bret H Goodpaster¹, and Heather H Cornell¹

¹Translational Research Institute for Metabolism and Diabetes, Florida Hospital, Orlando, FL, United States

Visceral adipose tissue (VAT) has been identified as a significant contributing factor to the metabolic complications of obesity and cardio-metabolic disease, thus its precise measurement is becoming more clinically relevant. Both MRI and DXA were used to measure different components of body composition including VAT, and these results were compared by gender. Both scan acquisitions took similar amounts of time, but DXA results were calculated automatically while MR data processing was completed offline, thus took more time. The results from this study indicate that DXA is a precise measure of only a portion of VAT while MRI can give a more accurate measurement of total VAT across the entire abdomen, potentially avoiding gender bias.

Phase Contrast Magnetic Resonance Imaging using Non-contrast-enhanced Magnetic Resonance Angiography using Balanced Steady-State Free-Precession Sequence and Time-Spatial Labeling Inversion Pulse: Measuring Left Gastric Vein Flow Velocity to Predict Esophageal Varices Development and Rupture

Akihiro Furuta¹, Hiroyoshi Isoda, Shigeshi Kohno, Koji Tokunaga, Ayako Ono, Rinpei Imamine, Rikiya Yamashita, Shigeki Arizono, Aki Kido, Naotaka Sakashita, and Kaori Togashi

¹Kyoto University, Kyoto, Japan

LGV flow velocity is clinically important to foresee esophageal varices development and rupture. But it is difficult to measure its velocity exactly by echo or only phase contrast MRI (PC-MRI). To measure LGV flow velocity, 2D PC-MRI were set perpendicularly across vessel segments in the cross-sectional slice position determined from 3D selective visualized LGV using non-contrast-enhanced MRA with balanced steady-state free-precession sequence and time-spatial labeling inversion pulse. LGV flow velocity of all subjects could be measured exactly. This method is useful to measure LGV flow velocity.

Assessment of Histological Differentiation in Gastric Cancers Using Whole-Volume Histogram Analysis of Apparent Diffusion Coefficient Maps

Zhengyang Zhou¹, Song Liu², Jian He², and Weibo Chen³

¹Department of Radiology, Drum Tower Hospital, School of Medicine, Nanjing University, Nanjing, People's Republic of China, ²Department of Radiology, Drum Tower Hospital, School of Medicine, Nanjing University, ³Philips Healthcare, Shanghai, People's Republic of China

Seventy-eight patients with gastric cancer were underwent MRI to investigate whether the histogram analysis of the entire tumor volume in ADC maps could differentiate between histological grades. A series of histogram parameters were calculated and correlated with the histological grade of the surgical specimen. There were significant differences in the 5th, 10th, 25th, and 50th percentiles, skew, and kurtosis between poorly and well-differentiated gastric cancers. There were correlations between the degrees of differentiation and histogram parameters, including the 10th percentile, skew, kurtosis, and max frequency. Histogram analysis of the ADC maps can be useful in differentiating between histological grades.

Diffusion-weighted MR Enterography imaging of the ileocecal segment: optimizing b-value for visually differentiating inflammatory and neoplastic lesions

Hao Yu¹, Daoyu Hu¹, Yaqi Shen¹, Zhen Li¹, Jianjun Li¹, Zi Wang¹, and Yanchun Wang¹

¹Department of Radiology, Tongji Hospital Tongji Medical College Huazhong University of Science and Technology, Wuhan, People's Republic of China

To evaluate the ability of conventional MR Enterography (MRE) including coronal and axial T1/T2 weighted imaging and Diffusion-weighted imaging with different b-values ($b=400, 600, 800, 1000, 1200, 1500, 3000 \text{ sec/mm}^2$) to visually illustrate inflammatory lesions and neoplastic lesions in the ileocecal region comparing with colonoscopy or surgical results. As a result, MRE and DWI were capable of revealing the lesions in the ileocecal segment. DWI was superior to detect lesions especially inflammations comparing with conventional MRE, and the optimal b value of DWI for MRE was 800 sec/mm^2 at 3T. Hyperintensity of ileocecal lesion on DWI with high b ($> 1000 \text{ sec/mm}^2$) value was more favor for tumor-like lesion.

Radiomics Model for Preoperative Prediction of Lymph Node Metastasis in Rectal Cancer after Neoadjuvant Chemoradiation Therapy

Haitao Zhu¹, Xiaoyan Zhang¹, Xiaoting Li¹, Yanjie Shi¹, Huici Zhu¹, and Yingshi Sun¹

¹Peking University Cancer Hospital and Institute, Beijing, People's Republic of China

Preoperative evaluation of lymph node metastasis in locally advanced rectal cancer remains a problem especially after neoadjuvant chemoradiation therapy treatment (NCT). This study proposed a MRI-based radiomics method to predict lymph node involvement in rectal after NCT. Beside the features from the tumor, features from the lymph nodes were also included for the construction of the radiomics model to increase the accuracy of prediction. 10-fold cross-validation among 300 patients produced ROC with average AUC=0.78. Independent validation with 118 patients produced ROC with AUC=0.81.

4977

Computer 60

Pretreatment diffusion kurtosis imaging for predicting the response of locally advanced rectal cancer to neoadjuvant chemoradiation therapy

Hongliang Sun¹, Yanyan Xu¹, Kaining Shi², and Wu Wang¹

¹Radiology, China-Japan Friendship Hospital, Beijing, People's Republic of China, ²Philips Healthcare China, Beijing, People's Republic of China

Diffusion kurtosis imaging (DKI) is an emerging technique, which could reflect restricted water diffusion within the complex microstructure of most tissues based on non-Gaussian diffusion model. It has been reported that DKI was used in central system diseases, tumor grade, even assessment of treatment response. However, there is limited research reported about the clinical application of DKI in rectal cancer, and the value of DKI in monitoring rectal cancer treatment was still unclear.

¹Radiology, Changhai Hospital of Shanghai, Shanghai, People's Republic of China, ²School of Pharmacy, Second Military Medical University, Shanghai, People's Republic of China, ³MR Research China, GE Healthcare, Shanghai, People's Republic of China

The effect of ROI size on ADC measurements in normal pancreatic tissue or pancreatic lesions have rarely been studied. This study investigated the influences of ROI size in ADC measurements for the differentiation between normal pancreas (NP), mass-forming chronic pancreatitis (MFCP) and pancreatic ductal adenocarcinoma (PDAC).

-
- 4985 Computer 68 Diffusion kurtosis imaging for differentiating tumor KRAS mutation status in rectal cancer
Yanyan Xu¹, Hongliang Sun¹, Kaining Shi², and Wu Wang¹
- ¹Radiology, China-Japan Friendship Hospital, Beijing, People's Republic of China, ²Philips Healthcare, China, Beijing, People's Republic of China
- Diffusion kurtosis imaging (DKI), which is a non-Gaussian diffusion-weighted model proposed by Jensen et al¹, has the potential to characterize both normal and pathologic tissue¹⁻³, meanwhile, providing a new option for tumor grade⁴ and assessment of treatment response⁵⁻⁷. Previous studies^{1-3,8} found that DKI could better account for restricted water diffusion within the complex microstructure of most tissues. To our knowledge, however, no study has included evaluation of DKI characteristic in rectal cancer, especially in the aspect of KRAS mutant, which associated with clinical treatment and prognosis of colorectal cancers⁹.
-
- 4986 Computer 69 The utilization of DDC value in detecting the status of LVI in rectal cancer patients at 3.0T MRI
 Guangwen Zhang¹ and Jinsong Zhang²
- ¹Xijing Hospital, xi'an, People's Republic of China, ²Xijing Hospital, People's Republic of China
- In this study, we aimed to investigate the value of DDC in assessing the status of lymphovascular invasion in patients with rectal cancer. Ninety-eight patients with rectal adenocarcinoma underwent DWI with 16 b-values at 3.0T MR system. We found there was a significant difference in DDC value between the LVI presence group (DDC=0.893±0.151×10⁻³mm²/s, n=46) and the LVI absent group (DDC=0.825±0.127×10⁻³mm²/s, n=52), (P=0.018). We speculate that DDC value derived from multi-b value DWI could be a useful functional parameter in detecting the status of LVI in rectal cancer patients.
-
- 4987 Computer 70 Measuring T1 and T2 of the small bowel wall at 3T
 Hannah Grace Williams^{1,2}, Penny A Gowland¹, Luca Marciani², Robert Scott³, Guruprasad Aithal^{2,3}, and Caroline L Hoad^{1,3}
- ¹Sir Peter Mansfield Imaging Centre, School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom, ²Nottingham Digestive Diseases Centre, School of Medicine, University of Nottingham, Nottingham, United Kingdom, ³NIHR Biomedical Research Unit in Gastrointestinal and Liver Diseases, Nottingham University Hospital, Nottingham, United Kingdom
- Available techniques to measure in-vivo bowel permeability are inadequate for stratifying patients to identify those at risk of complications from increased bowel permeability. T₁ and T₂ measurements could potentially be indicators of changes in bowel wall structure and thus permeability. We have measured the T₁ and T₂ of the bowel wall to be 1.68±0.57 s and 0.08 ±0.02 s respectively. We found significant variations between and within subjects. However it is currently unknown whether some of these variations are real and some due to errors in the measurement process.
-
- 4988 Computer 71 MR versus CT Imaging for Identifying the Etiology of Abdominal Pain in Emergency Department Patients
 Michael Dean Repplinger¹, Perry J Pickhardt², Rebecca L Bracken¹, Douglas R Kitchin³, Jessica B Robbins², Timothy J Ziemlewicz², and Scott B Reeder²
- ¹Emergency Medicine, University of Wisconsin - Madison, Madison, WI, United States, ²Radiology, University of Wisconsin - Madison, Madison, WI, United States, ³Radiology, St. Mary's Hospital, Madison, WI, United States
- Our study aimed to evaluate the diagnostic accuracy of MR versus CT for identifying the etiology of abdominal pain in emergency department patients. This is a prospective study that included patients ≥12-years-old who were being evaluated for possible appendicitis. All patients underwent both MR and CT; images were interpreted by three radiologists who were blind to the patient's outcome. There were 113 instances of acute abdominal processes (15 different diagnoses). The overall accuracy of NC-MR, CE-MR, and CT was 77%, 83%, and 90% for individual reads and 82%, 84%, and 94% for consensus reads.
-
- 4989 Computer 72 Chemical Shift Effect Predicting Lymph Node Status in Rectal Cancer using High-Resolution MR Imaging with Node-for-node Matched Histopathological Validation
 chongda zhang¹, hongmei zhang¹, feng ye¹, yuan liu¹, and chunwu zhou¹
- ¹Department of Diagnostic Radiology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, People's Republic of China
- To evaluate the value of chemical shift effect (CSE), as well as other criteria for the prediction of lymph node status. Lymph nodes harvested from transversely whole-mount specimens were compared with in vivo and ex vivo images to obtain MR characteristics including CSE, as well as other predictors of 255 benign and 35 metastatic nodes. Our results revealed that CSE is a reliable predictor for differentiating benign from metastatic lymph nodes. Other predictors of nodal location, border, signal intensity and minimum distance to rectal wall were also proved to be useful for the diagnosis.

[A quantitative relationship between \$R_2^*\$ and deoxyhemoglobin levels in calf muscle](#)

Xexin Hao¹, Gwenael Layec², Corey R. Hart³, Christopher C. Conlin⁴, Kristi Carlston⁴, Vivian S. Lee⁴, and Jeff L. Zhang⁴

¹Department of Electrical and Computer Engineering, University of Utah, Salt Lake City, UT, United States, ²Department of Internal Medicine, University of Utah School of Medicine, Salt Lake City, UT, United States, ³Department of Exercise and Sports Science, University of Utah, UT, United States, ⁴Department of Radiology and Imaging Sciences, University of Utah, Salt Lake City, UT, United States

This study examined the relationship between R_2^* measurements from BOLD MRI and deoxyhemoglobin (HHb) measurements from near-infrared spectroscopy (NIRS) in calf muscle of subjects with varying degrees of peripheral artery disease (PAD). Following plantar-flexion exercise, the time required for R_2^* and HHb to recover to resting-state values was recorded. Linear regression was used to relate recovery time between R_2^* and HHb. This quantitative relationship enables estimation of HHb from MRI-measured R_2^* , which can help to improve the assessment of PAD since MRI can easily be performed for muscle tissue that is too deep for NIRS evaluation.

[Noninvasive Measurement of Calf Muscle Perfusion Immediately after Plantar Flexion Exercise in Elderly Patients with Heart Failure and Preserved Ejection Fraction](#)

Robert A. Kraft¹, Craig A. Hamilton¹, Peter H. Brubaker², W. Scott Hoge³, M. Constance Linville⁴, J. Thomas Becton⁵, Richard J. Thompson⁶, Mark J. Haykowsky⁷, and Dalane W. Kitzman⁵

¹Biomedical Engineering, Wake Forest University School of Medicine, Winston-Salem, NC, United States, ²Health and Exercise Science, Wake Forest University, Winston-Salem, NC, United States, ³Radiology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, ⁴Department of Biomedical Engineering, Wake Forest University School of Medicine, Winston-Salem, NC, United States, ⁵Cardiology, Wake Forest University School of Medicine, Winston-Salem, NC, United States, ⁶Bioengineering, University of Alberta, Edmonton, Canada, ⁷College of Nursing and Health Innovation, University of Texas at Arlington, Arlington, TX

The pathophysiology of Heart Failure Patients with Preserved Ejection Fraction is poorly understood but there is increasing evidence that skeletal muscle blood flow and metabolism play important roles in this disease. Accurately and non-invasively measuring skeletal muscle blood flow with sufficient temporal resolution to measure skeletal muscle blood flow dynamics in individual muscles is challenging. We present a optimized version of pseudo-Continuous ASL capable of measuring blood flow map of the calf every 16 seconds. Data from two healthy adults is presented.

Computer 27

[Stimulated Echo DTI in skeletal muscle of patients with Becker Muscular Dystrophy](#)

Celine Baligand¹, Jędrzej Burakiewicz¹, Melissa T. Hooijmans¹, Olivier Scheidegger², Matt G. Hall³, Paola Porcari⁴, Erik H. Niks⁵, Pierre G. Carlier², Christopher Clark³, Andrew Blamire⁴, Jan J.G.M. Verschuuren⁵, and Hermien E. Kan¹

¹Department of Radiology, Leiden University Medical Center, C.J. Gorter Center for High-field MRI, Leiden, Netherlands, ²NMR laboratory, Institute of Myology, Paris, France, ³Institute of Child Health, University College of London, London, United Kingdom, ⁴Institute of Cellular Medicine and Newcastle Magnetic Resonance Centre, Newcastle University, Newcastle upon Tyne, United Kingdom, ⁵Department of Neurology, Leiden University Medical Center, Leiden, Netherlands

Cellular sizes in skeletal muscle are significantly larger than in the brain. Therefore standard spin-echo (SE)-DTI with inherently short diffusion times may lack sensitivity for the study skeletal muscle of neuromuscular disorders (NMDs). Alternatively, stimulated-echo (STE)-DTI allows for much longer diffusion times, increasing sensitivity to cell size. Due to the challenges presented by fat replacement STE-DTI has not been previously applied in NMDs. Here, we show that STE-DTI is feasible in Becker Muscular Dystrophy patients, and can detect FA differences compared to healthy controls in mildly affected muscles.

²Department of Diagnostic and Interventional Neuroradiology, Klinikum rechts der Isar, Technical University of Munich, Munich, Germany,

³Philips Research Laboratories, Hamburg, Germany

Chemical shift encoding-based water-fat MRI derived proton density fat fraction (PDFF) of the paraspinal muscles has been emerging as an important surrogate marker in subjects with intervertebral disc disease, osteoporosis, sarcopenia, and neuromuscular disorders. However, measurements of paraspinal muscle PDFF are currently limited in clinical routine due to the required time-consuming manual segmentation procedure. The present study aimed to develop an automatic segmentation algorithm of the paraspinal muscles at the lumbar spine based on water-fat MRI and compared the performance of this algorithm to ground truth data based on manual segmentation.

¹High-Field MR Center, Department of Biomedical Imaging and Image-Guided Therapy, Medical University of Vienna, Vienna, Austria, ²Department of NMR Spectroscopy and Mass Spectrometry, Faculty of Chemical and Food Technology, Slovak University of Technology, Bratislava, Slovakia, ³Christian Doppler Laboratory for Clinical Molecular MR Imaging, Vienna, Austria, ⁴University of Oxford Centre for Clinical Magnetic Resonance Research, University of Oxford, John Radcliffe Hospital, Oxford, United Kingdom, ⁵Department of Imaging Methods, Institute of Measurements Science, Slovak Academy of Sciences, Bratislava, Slovakia, ⁶Division of Endocrinology and Metabolism, Department of Medicine III, Medical University of Vienna, Vienna, Austria, ⁷Center of Sport Science and University Sport, University of Vienna, Vienna, Austria

Carnitine plays an important role in fat metabolism. A long-echo time proton magnetic resonance spectroscopy protocol was implemented for detection of skeletal muscle acetylcarnitine during the day and after exercise on a clinical 7T scanner in the thigh (vastus lateralis) muscle. Our observation point towards diurnal changes of acetylcarnitine concentration which tended to be higher in the morning than after lunch. Moreover, following 10 minutes of high-intensity exercise the concentration significantly increased and again significantly decreased 15 minutes after cessation of the exercise. Our data emphasize the need for strict standardization, physical activity and dietary conditions for the measurement of the acetylcarnitine/carnitine.

[Normalized STEAM-based DTI parameters allow robust assessment of muscle tears in football players.](#)

Chiara Giraudo¹, Stanislav Motyka¹, Michael Weber², Manuela Karner¹, Christoph Resinger³, Siegfried Trattnig¹, and Wolfgang Bogner¹

¹Department of Biomedical Imaging and Image-guided Therapy-MR Centre of Excellence, Medical University of Vienna, Vienna, Austria, ²Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria, ³Orthopedic Department, Evangelisches Krankenhaus Wien, Vienna, Austria

STEAM-based DTI was applied to investigate lower limbs' muscle tears in athletes using the contralateral muscles as reference. To account for possible physiological differences in DTI metrics between right and left limb, a ratio between two ROIs on the injured side (i.e., one on the tear and one on a healthy area) and two ROIs on the contralateral limb (i.e., both on healthy areas) was used. The ratio showed that structural changes, expressed by modifications in MD, FA, RD, fibers' number and length, occur in muscle tears and are quantifiable by DTI. These findings are expected to improve the therapeutic management of muscle injuries.

Computer 32

[Paraspinal Muscle Changes with Chronic Low Back Pain by Using 3.0T MR Diffusion Tensor Imaging Technology](#)

Li Yiwen¹, Yuan Huishu¹, and Xie Lizhi²

¹Radiology, Peking University Third Hospital, Beijing, People's Republic of China, ²GE Healthcare, MR Research China, Beijing, People's Republic of China

The purpose of the current study is to assess the potential difference of multifidus muscle between non-specific chronic low back pain patients and the healthy individuals using DTI and to compare the sensitivity of DTI to conventional lumbar MRI in detecting muscle pathological changes. DTI and conventional MRI parameters were obtained including FA, ADC, MD and tCSA, fCSA, fCSA/tCSA ratio. Compared to the healthy individuals, NCLBP patients demonstrated differences in DTI parameters of bilateral multifidus muscles. We conclude that DTI is more sensitive in detecting paraspinal muscle pathological changes in the early stage of lumbar degeneration than conventional lumbar MRI.

[ROI-based Evaluation of Diffusion Tensor Metric of Skeleton Muscles](#)

Sarah Keller¹, Jin Yamamura², Shaheen Ahmed³, Gerhard Adam², Nancy Rollins³, and Zhiyue J. Wang³

¹Diagnostic and Interventional Radiology and Nuclear Medicine, University Medical Center Hamburg Eppendorf, Hamburg, Germany, ²Diagnostic and Interventional Radiology and Nuclear Medicine, University Medical Center Hamburg Eppendorf, Hamburg, ³Radiology, University of Texas Southwestern Medical Center, Dallas, TX, United States

This study evaluates and compares a pixel-based and ROI-based quantification of DTI-metrics for skeleton muscles in healthy subjects. Besides SNR, an "intra-ROI diffusion direction dispersion angle" is evaluated as a quantitative metric to assess reliability of ROI-based DTI-metrics

-
- 5000 **Computer 35** **MRI/S Assessment of Skeletal Muscle Morphology and Energetics in Mdx Muscle Injured Mouse as a Model for Duchenne Muscular Dystrophy**
HASAN ALSAID¹, Mary Rambo¹, Tinamarie Skedzielewski¹, Alan McDougal², Fritz Kramer², and Beat Jucker¹

¹Bioimaging, IV/IVT, PTS, GlaxoSmithKline, King of Prussia, PA, United States, ²Muscle Metabolism DPU, MPC TAU, GlaxoSmithKline, King of Prussia, PA, United States
- The purpose of this study was to longitudinally and non-invasively assess the effect of eccentric contraction induced muscle damage in the Mdx mouse as a model for Duchenne Muscular Dystrophy using non invasive MRI and MRS. Mdx mice showed a significant increase in absolute T2 value at baseline and a severe increase in the exercised leg at Day 2 following injury compared to the Wild type group. PCr/Pi ratios decreased in the Mdx group acutely upon exercise induced damage and resolved by day 7. The fraction of Undamaged Limb Force is correlated negatively with T2 and positively with the PCr/Pi ratios.
-
- 5001 **Computer 36** **Development of an MR-Compatible Ergometer for Use in Quantifying Human Skeletal Muscle Bioenergetics During Supine Dynamic Contractions of the Knee Extensors**

¹Human Magnetic Resonance Center, Institute for Applied Life Sciences (IALS), University of Massachusetts, Amherst, MA, United States, ²Department of Mechanical & Industrial Engineering, University of Massachusetts, Amherst, MA, United States, ³Kinesiology, University of Massachusetts, Amherst, MA, United States
- The goal of this project was to develop an MR-compatible, multi-modal ergometer for the reliable measurement of human skeletal muscle torque, velocity, power and joint angle during 31P MRS studies of knee extensor muscle energetics. Intracellular [PCr], [Pi] and pH were determined in the vastus lateralis with 4-s time resolution during 4 min of maximal voluntary isokinetic contractions at 240 degrees per second, with a 30 degree range of motion. High S/N for both the MRS and power data indicate that this tool will be useful in future studies of in vivo muscle bioenergetics.
-
- 5002 **Computer 37** **Study of correlation between multifidus muscles atrophy and degenerative diseases of lumbar spine in patients with low back pain using MRI**
Jiufa Cui¹, Mingqian Huang², and Mark Schweitzer²

¹Affiliated hospital of Qingdao University, Qingdao, People's Republic of China, ²Department of Radiology, stony brook university hospital, Stony brook, NY, United States
- Multifidus muscles (MF) atrophy are common in patients with Low back pain (LBP). Degenerative diseases of the lumbar spine, such as disc herniation, disc degeneration and facet joint osteoarthritis, are leading cause of LBP. Various studies have previously focused on the relationship between MF atrophy and disc degeneration, disc herniation. However, the results are inconsistent. Besides, no study for the correlation between MF atrophy and facet joint osteoarthritis has previously been conducted. This study will investigate the correlation between MF atrophy and disc degeneration, disc herniation, facet joint osteoarthritis using MRI.
-
- 5003 **Computer 38** **Repeatability of quantitative muscle strain and strain rate measurements by means of synchronous dynamic muscle MRI during electrical muscle stimulation**
Xeni Deligianni^{1,2}, Michele Pansini³, Meritxell Garcia⁴, Anna Hirschmann⁴, Arno Schmidt-Trucksäss⁵, Oliver Bieri^{1,2}, and Francesco Santini^{1,2}

¹Radiology, Division of Radiological Physics, University of Basel Hospital, Basel, Switzerland, ²Biomedical Engineering, University of Basel, Basel, Switzerland, ³Ricerche Diagnostiche Srl, Bari, Italy, ⁴Musculoskeletal Radiology, Clinic of Radiology and Nuclear Medicine, University of Basel Hospital, Basel, Switzerland, ⁵Sports Medicine, University of Basel, Switzerland
- Stimulation of the quadriceps muscle group of the thigh and synchronous phase contrast imaging at a 3T MRI scanner were applied to six healthy volunteers, to assess repeatability of the dynamic strain and strain rate maps. The repeatability was higher for strain (ICC=0.665-0.751) than for strain rate (ICC=0.242-0.571) and the correlation of the results increased with longer intra-scan rest periods. In conclusion, strain and strain rate measured with synchronous MRI of EMS-controlled muscle contraction are repeatable, though attention should be paid to intra-stimulation rest periods.
-
- 5004 **Computer 39** **Assessment of Spontaneous Mechanical Activities in Musculature by Simultaneous Multi-Slice Diffusion-Weighted Imaging and Fiber-Tractography Data Validation**
Martin Schwartz^{1,2}, Petros Martirosian¹, Guenter Steidle¹, Michael Erb³, Bin Yang², and Fritz Schick¹

¹Section on Experimental Radiology, University of Tuebingen, Tuebingen, Germany, ²Institute of Signal Processing and System Theory, University of Stuttgart, Stuttgart, Germany, ³Biomedical Magnetic Resonance, University of Tuebingen, Tuebingen, Germany
- Simultaneous multi-slice diffusion-weighted imaging (DWI) was applied on human right calf for imaging Spontaneous Mechanical Activity in Musculature (SMAM) in multiple slices in order to improve assessment of the spatial extension of these spontaneous activities. For data validation, diffusion-tensor images (DTI) were acquired with subsequent fiber tractography to fuse anatomical fiber orientation to spontaneous events in DWI. High accordance between both modalities and reliable application of simultaneous multi-slice diffusion-weighted imaging is demonstrated.

Computer 40

Estimation of the Sensitivity Characteristics and Detection Capability of Diffusion-Weighted MR Sequences in Imaging Spontaneous Mechanical Activity in Musculature

Martin Schwartz^{1,2}, Guenter Steidle¹, Petros Martirosian¹, Ander Ramos-Murguialday^{3,4}, Alto Stemmer⁵, Bin Yang², and Fritz Schick¹

¹Section on Experimental Radiology, University of Tuebingen, Tuebingen, Germany, ²Institute of Signal Processing and System Theory, University of Stuttgart, Stuttgart, Germany, ³Institute for Medical Psychology and Behavioural Neurobiology, University of Tuebingen, Tuebingen, Germany, ⁴Neurotechnology Laboratory, TECNALIA Health Department, San Sebastian, Spain, ⁵Siemens Healthcare GmbH, Erlangen, Germany

Spontaneous mechanical activity in musculature (SMAM) can be observed from time to time in diffusion-weighted images (DWI) of the human lower leg. In DWI, motion sensitivity is usually restricted to a time window between diffusion-sensitizing dephasing and rephrasing gradients. Capabilities to detect SMAM occurring outside this time window by DWI are expected to be clearly reduced. The temporal sensitivity of diffusion-weighted sequences to SMAM is evaluated by varying diffusion-sensitizing time. In addition, concurrent surface electromyography (sEMG) measurements were performed in order to reveal the temporal correlation of the events in both modalities.

Tongue muscle architecture is suspected to be important in the prediction of speech and swallowing complications after surgery. The tongue contains areas of crossing muscle fibres unable to be resolved by diffusion tensor imaging (DTI). We show that constrained spherical deconvolution (CSD) is able to distinguish these crossing fibres *ex vivo* and *in vivo* using a clinically acceptable scan time of 10 min. Also, we show improved tractography in CSD compared to DTI, allowing segmentation of different tongue muscles which conforms to known anatomy.

Magnetic Resonance Methods for Quantitative Evaluation of Intramuscular Adipose Tissue

Alexandra Grimm^{1,2}, Heiko Meyer², Mathias Nittka², Esther Raithe², Oliver Chaudry¹, Andreas Friedberger¹, Michael Uder³, Wolfgang Kemmler¹, Klaus Engelke¹, and Harald H. Quick^{1,4,5}

¹Institute of Medical Physics, University Erlangen-Nuremberg, Erlangen, Germany, ²Product Definition & Innovation, Siemens Healthcare GmbH, Diagnostic Imaging, Magnetic Resonance, Erlangen, Germany, ³Institute of Radiology, University Hospital Erlangen, Erlangen, Germany, ⁴Erwin L. Hahn Institute for Magnetic Resonance Imaging, University Duisburg-Essen, Essen, Germany, ⁵High Field and Hybrid MR Imaging, University Hospital Essen, Essen, Germany

Intramuscular adipose tissue directly affects physical performance. 56 subjects (80 ± 5 yrs) with sarcopenia and 23 physically well-trained subjects (28 ± 4 yrs), all male, were examined at the thigh on a 3T MR system using quantitative MRI and MRS sequences. The results show that the use of spectroscopy involves challenges with regard to representative assessment of the entire muscle and might overestimate fat in low-fat tissues as muscle tissue. Furthermore, 2pt in comparison to 6pt Dixon sequences should be used with caution for quantitative evaluation, while multi-echo Dixon sequences are capable of quantifying intramuscular adipose tissue.

5008

Heterogeneity of Quadriceps Muscle Activation during Isometric Contractions as revealed by Velocity Encoded Phase Contrast (VE-PC) Imaging.

Toshiaki Oda¹, Vadim Malis², Taija Juutinen Finni³, and Shantanu Sinha⁴

¹Hyogo University of Teacher Education, Katō, Hyōgo, Japan, ²Physics, UC San Diego, San Diego, CA, United States, ³The University of Jyväskylä, Jyväskylä, Finland, ⁴Radiology, UC San Diego, San Diego, CA, United States

The relative contributions of the four compartments of the quadriceps to force production are clinically very important information. The spatial and temporal heterogeneity of velocity and strain, (surrogate biomarkers of neural activation) was determined, within and between different compartments of normal quadriceps and along the proximo-distal (Z) axis, during isometric contraction using gated VE-PC imaging. Statistically significant differences were determined, within the same muscle compartment, across compartments and between different Z axis positions. Determining how these change in the diseased state e.g. post-ACL tear will be important in tailoring rehabilitative strategies, with particular relevance to preventing early onset of osteoarthritis.

Quantitative NMR imaging of short and long T2 components in the SKM tissue by 1H T2- relaxometry study

Teresa Gerhalter^{1,2}, Pierre-Yves Baudin³, Noura Azzabou^{1,2}, Eriky Caldas^{1,2}, Harmen Reyngoudt^{1,2}, Pierre Carlier^{1,2}, and Benjamin Marty^{1,2}¹Institute of Myology, NMR Laboratory, Paris, France, ²CEA, DRF, I²BM, MIRCen, Paris, France, ³CRIS, Tournai, Belgium

Muscle water T2 is currently being used to assess and monitor the pathology of neuromuscular disorders. The vascular signal of water T2 is close to the one of fat, which might have an impact on the fat fraction quantification using a 2-component fitting approach on MSME data. Here, we examined the impact of long water T2 variations during exercise on fat quantification using the 2-component extended phase graph (EPG) model. Exercise increased the short T2 and the ratio between the amplitudes of short and long T2 signals suggesting an impact of the vascular space on the fat fraction quantification.

T2-weighted Dixon TSE for accelerated simultaneous grading of whole body skeletal muscle fat infiltration and edema in patients with neuromuscular diseases

Sarah Schlaeger¹, Elisabeth Klupp¹, Dominik Weidlich², Barbara Cervantes², Marcus Deschauer³, Benedikt Schoser⁴, Sarah Bublitz², Federica Montagnese⁴, Christoph Katemann⁵, Hendrik Kooijman⁵, Ernst J. Rummeny², Claus Zimmer¹, Jan S. Kirschke¹, and Dimitrios C. Karampinos²¹Department of Diagnostic and Interventional Neuroradiology, Technical University of Munich, Munich, Germany, ²Department of Diagnostic and Interventional Radiology, Technical University of Munich, Munich, Germany, ³Department of Neurology, Technical University of Munich, Munich, Germany, ⁴Friedrich-Baur-Institut, Ludwig-Maximilians-University, Munich, Germany, ⁵Philips Healthcare, Hamburg, Germany

The assessment of fatty infiltration and edema in the whole body musculature of patients with neuromuscular diseases typically requires the separate performance of a T₁-weighted sequence and a fat suppressed T₂-weighted sequence. T₂-weighted Dixon TSE enables the generation of T₂-weighted fat-separated and water-separated images, which could be used to simultaneously assess fatty infiltration and edema and to reduce total scan time. The present study examines the diagnostic performance of whole body T₂-weighted Dixon TSE imaging in 10 patients with neuromuscular diseases.

Computer 47

Magnetic resonance imaging estimates of intermuscular fat density in the thigh in sarcopenia population: correlation with physical performances

Yu Xin Yang¹, Wee Shiong Lim^{1,2}, Mei Sian Chong¹, Laura Tay^{1,2}, Suzanne Yew¹, Audrey Yeo¹, and Cher Heng Tan³¹Institute of Geriatrics and Active Ageing, Tan Tock Seng Hospital, Singapore, Singapore, ²Geriatric Medicine, Tan Tock Seng Hospital, Singapore, Singapore, ³Diagnostic Radiology, Tan Tock Seng Hospital, Singapore, Singapore

Emerging evidence suggests that intermuscular fat (IMF) accumulation is associated with reduced muscle quality and increased risk of physical limitation. However, the impact and mechanism of IMF in sarcopenia or sarcopenic obesity (SO) are still unclear. MRI is a promising tool for early detection of sarcopenia and SO. This may translate to use in clinical trials and in future clinical practice, where quantitative assessment may become standard of care. . This study aims to study a new index that we term "IMF density", shows promise as an important quantitative variable that reflects patients' physical performances.

Highly Efficient Bi-Component T2* Mapping of the Knee using Ultra-short Echo Ramped Hybrid Encoding

Hyungseok Jang¹, Fang Liu¹, Richard Kijowski¹, and Alan B McMillan¹¹Department of Radiology, University of Wisconsin, Madison, WI, United States

T2* analysis is used in musculoskeletal imaging to characterize tendon, meniscus, and cartilage in human joints. With the development of high performance gradient systems, ultrashort time echo (UTE) imaging has become more feasible, allowing robust bi-component of short and long T2* tissue components. Many studies have been performed to realize robust and clinically feasible bi-component T2* imaging, but the long acquisition time required to obtain multiple echo images remains challenging. In this study, we propose a novel, rapid imaging scheme for bi-component T2* analysis, based on ramped hybrid encoding (RHE) that allows robust bi-component T2* estimation within a single scan.

Bi-exponential T2* mapping of peripheral nerve from in-vivo human scans with a 3D UTE cones sequence.

Daehyun Yoon¹ and Brian Hargreaves¹¹Department of Radiology, Stanford university, Palo Alto, CA, United States

Previous studies with nerve samples have demonstrated the existence of multiple signal components with different T2 or T2* relaxation times in peripheral nerves. The short- T2* signal component has received significant research attention, based on its correlation with myelin health of nerve fiber in many neurological diseases. However, little research has been conducted with in vivo human scans to separate the short-T2* component and the long-T2* component in peripheral nerves. Using a 3D ultra-short echo time (UTE) cones sequence, we demonstrate the feasibility of capturing and separating both bi-exponential T2* signal components from in vivo human nerve scans

Type 2 diabetes alters bone marrow fat content and marrow blood flow as seen by IDEAL-IQ and DCE MRI

Lin Yuan¹, Zha Yunfei¹, Lin Hui², and Wu Bing²

¹Renmin Hospital of Wuhan University, wuhan, People's Republic of China, ²GE healthcare, wuhan, China

To explore the effect of type 2 diabetes on bone marrow fat content(BMF) and marrow blood flow, as well as the association of the bone marrow fat content and marrow perfusion in type 2 diabetes mellitus (T2DM) patients. 26 healthy nondiabetic subjects and 24 T2DM patients underwent lumbar IDEAL-IQ and DCE-MRI. The marrow fat content(BMF) and the marrow perfusion parameters (Ktrans, Kep, Ve) of lumbar vertebra all showed significant difference between T2DM patients and the healthy individuals. In addition, transfer constant (Ktrans) was negatively correlated with BMF in T2DM patients.

Knee-to-coil automatic distance detection for misalignment alert system during MRI acquisition

Takamasa Sugiura¹, Toshimitsu Kaneko¹, Tomoyuki Takeguchi¹, Kensuke Shinoda², Takuya Fujimaki², and Hiroshi Takai²

¹Toshiba Corporation, Kawasaki, Japan, ²Toshiba Medical Systems Corporation, Otawara, Japan

For high quality knee MRI image acquisition, the coil must be centrally aligned with the knee. However, precise alignment can suffer from patient motion and is currently performed by eye. We propose a method to automatically measure the misalignment between coil and knee to alert the clinical operator. This is done by calculating the distance between the coil and the knee joint gap by processing the localizer image with a machine learning technique, which was achieved with a mean accuracy of 3.3 mm. Our experiments further indicated a safe margin for knee-to-coil misalignment within a threshold of 20 mm.

Metal Artifact Reduction MRI around Cobalt-Chromium Arthroplasty Implants: The Negative Effect of Long Echo Trains on Implant-related Artifact

Neil Mithilesh Kumar¹, Cesar Netto, Lew Schon, and Jan Fritz²

¹Radiology, Johns Hopkins Hospital, Baltimore, MD, United States, ²Radiology, Johns Hopkins Hospital

We demonstrate the negative effects of increasing echo train lengths on total implant-related artifact in a setting of controlled bandwidth, echo spacing and effective echo time. For the practical purpose of metal artifact reduction sequence MR imaging with use of turbo spin echo pulse sequences, high receiver bandwidth can be recommended as the first line means, whereas long echo train length may not be recommended and used cautiously due to the potential of substantial degradation of image quality.

5018

Compressed Sensing SEMAC MRI of Total Knee Arthroplasty Implants: Intra-subject Comparison at 1.5 and 3 Tesla

Jan Fritz¹, Benjamin Fritz², Gaurav K Thawait¹, Wesley D Gilson³, Christoph Forman⁴, Esther Raithel⁴, Mathias Nittka⁴, Robert Sterling¹, and Paul Khanuja¹

¹The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²Orthopaedic University Hospital Balgrist, ³Siemens Healthcare USA, ⁴Siemens Healthcare GmbH

Because susceptibility artifacts increase with field strength, MRI of knee arthroplasty implants is commonly performed at 1.5T. However, 3T MRI offers substantially higher SNR and may be the only available option. SEMAC can achieve substantial metal artifact reduction at 3T, but requires prolongs scan times. Capitalizing on the inherent sparsity of SEMAC data, compressed sensing-based pseudo-randomized undersampling and iterative reconstruction can substantially accelerate data acquisition. We show the clinical feasibility of highly accelerated 3T MRI of CoCr knee arthroplasty implants using a compressed sensing SEMAC TSE sequence with metal artifact reduction capabilities and acquisition times similar to 1.5T.

Computer 55

3D IR-UTE-Cones for High Contrast MR Imaging of Lamellar Bone

Anthony S. Tadros¹, Justin W. West², Amin Nazaran¹, Ya-Jun Ma¹, Heinz R. Hoenecke², Jiang Du¹, and Eric Y. Chang^{1,3}

¹Department of Radiology, University of California, San Diego Medical Center, La Jolla, CA, United States, ²Orthopedic Surgery, Scripps Clinic, La Jolla, CA, United States, ³Radiology Service, VA San Diego Healthcare System, San Diego, CA, United States

Lamellar bone is poorly evaluated using conventional magnetic resonance (MR) imaging secondary to its inherently short T2 relaxation time. Rather, the contours of lamellar bone are often inferred based on marrow signal. In the setting of shoulder instability or pre-operative planning for arthroplasty, rotator cuff integrity and glenoid bone defects are frequently assessed using both MRI and computed tomography (CT), respectively. An MR imaging technique to directly image lamellar bone could potentially eliminate the need for a CT scan and be particularly useful for young patients with acute shoulder instability.

Application of Simultaneous Multi-Slice TSE in High-Resolution Hand and Foot Imaging

Feifei Gao¹, Yinghui Ge¹, Yi Wei¹, Shufang Wei¹, Xiaojing Kan¹, Panli Zuo², Dingxin Wang³, and Tianyi Qian²

¹Radiology, Zhengzhou University People's Hospital, Zhengzhou, People's Republic of China, ²Siemens Healthcare, MR Collaborations NE Asia, Beijing, People's Republic of China, ³Siemens Medical Solutions USA, Inc., MN, United States

The turbo spin echo sequence is one of the most frequently used MR sequences in routine musculoskeletal exams. Its short scan time has allowed it to become a popular clinical choice because it reduces the possibility of motion artifact especially in patients with low tolerance for MR exams. In order to further shorten the scan time and increase temporal and/or spatial resolution, simultaneous multi-slice technique has been widely applied during brain image acquisition. In this study we tried to apply a prototypical SMS-TSE sequence to hand and foot imaging. Compared to the standard TSE sequence, the SMS-TSE had the same image quality and a shorter acquisition time.

Simultaneous multi-slice TSE imaging of the hip joint: Acquisition time reduction and imaging quality.

Mayuko Haraikawa¹, Masashi Suzuki¹, Yuki Hara¹, Kayu Takezawa¹, Nanami Okano¹, Iichiro Osawa¹, Kaiji Inoue¹, Eito Kozawa¹, Junji Tanaka¹, Keisuke Watarai², Taishi Unezawa¹, Atsushi Kondo¹, Hiroshi Imai³, Thomas Beck⁴, Dingxin Wang⁵, and Mamoru Niitsu¹

¹radiology, Saitama Medical University Hospital, Saitama, Japan, ²orthopedics, Saitama Medical University Hospital, Saitama, Japan, ³Siemens Healthcare K.K, Tokyo, Japan, ⁴Siemens Healthcare GmbH, Erlangen, Germany, ⁵Siemens Healthcare, Minneapolis, United States

Simultaneous-Multi-Slice Turbo-Spin-Echo (SMS TSE) protocols were added to our conventional (CNV) hip joint MR examination in 21 patients. Image quality of acetabular labrum, articular cartilage, round ligament and bony trabeculae were evaluated by three reviewers and showed comparable image quality, whereas SMS was slightly better for bony trabeculae. If CNV is substituted by SMS, total scan time can be reduced by approximately 40%. Although SMS protocols showed higher specific absorption rate (SAR), it only accounted for 20% of scans which exceeded the first level of SAR limit. SMS could be applied to clinical examination with advantage of acquisition time reduction.

Age-related differences in quantitative muscular contraction parameters measured by synchronous dynamic MRI of electrical muscle stimulation

Xeni Deligianni^{1,2}, Christopher Klenk³, Meritxell Garcia⁴, Michele Pansini⁵, Anna Hirschmann⁴, Arno Schmidt-Trucksäss³, Oliver Bieri^{1,2}, and Francesco Santini^{1,2}

¹Radiology, Division of Radiological Physics, University of Basel Hospital, Basel, Switzerland, ²Biomedical Engineering, University of Basel, Basel, Switzerland, ³Sports Medicine, University of Basel, Basel, Switzerland, ⁴Musculoskeletal Radiology, Clinic of Radiology and Nuclear Medicine, University of Basel Hospital, Basel, Switzerland, ⁵Ricerche Diagnostiche Srl, Bari, Italy

Stimulation of the quadriceps muscle group of the thigh and synchronous phase contrast imaging at a 3T MRI scanner were applied to six young and 13 elderly volunteers, to assess age-related differences. Dynamic strain and strain rate maps were reconstructed. Age-related differences both for strain and strain rate were observed and the significance of the difference increased when the vastus intermedius muscle was included.

5026

Computer 62

Utilization of phase data to improve image contrast in UTE MRI at 3T

Aiming Lu¹, Joel P Felmlee¹, and Krzysztof R Gorny¹

¹Mayo Clinical, Rochester, MN, United States

MR imaging with UTE/ZTE sequences has attracted significant clinical interest in recent years due to their many inherent merits, such as resilience to motion and flow artifacts, capability to achieve high acceleration factors and minimize acoustic noise, as well as capability to capture signal from tissues with ultra-short T2s/T2*s. However, ZTE acquisitions and many UTE acquisitions require the use of low flip angles and, as a consequence, deliver mostly proton density weighted contrast. Magnetization preparation such as fat suppression with UTE/ZTE is time consuming as k-space center data needs to be acquired every TR. Therefore, exploiting the other inherent information such as signal phase is important. In this work, we demonstrate that phase images obtained with UTE can be exploited to enhance the tissue contrast such as fat/water differentiation and enable improved cortical bone visualization, and generate susceptibility map in the volunteer knee on a clinical scanner at 3T.

Improvement of 3D diffusion-prepared MR neurography in the extremities using improved diffusion-sensitized driven-equilibrium (iDSDE) with phase-cycling turbo field echo sequence

Takayuki Sakai¹, Masami Yoneyama², Atsuya Watanabe¹, Iain Ball³, Toshiaki Miyati⁴, and Noriyuki Yanagawa¹

¹Eastern Chiba Medical Center, Chiba, Japan, ²Philips Electronics Japan, Tokyo, Japan, ³Philips Electronics Australia, North Ryde, Australia, ⁴Kanazawa University, Ishikawa, Japan

Diffusion-sensitized driven-equilibrium with phase-cycling T1-turbo field-echo (pc-DSDE) enables the visualization of peripheral nerves. However, pc-DSDE has several problems, such as low image stability, poor reproducibility, and partially remaining venous signals. To solve these problems, we improved DSDE pre-pulse module (iDSDE) including B1-insensitive RF pulse and orthogonally combined motion- and diffusion-sensitized gradient scheme. iDSDE showed better visualization of peripheral nerves without contamination of veins.

5028

Computer 64

Lipid Suppression Around Metal Implants Using a B1-Optimized Adiabatic Inversion Pulse

S Sivaram Kaushik¹, Andrew Huettner², Peter LaViolette³, Andrew Nencka³, and Kevin Koch³

¹MR Applications and Workflow, GE Healthcare, Waukesha, WI, United States, ²MR Systems Engineering, GE Healthcare, Waukesha, WI, United States, ³Radiology, Medical College of Wisconsin, Milwaukee, WI, United States

A nonlinear iterative optimization algorithm was used to design an adiabatic inversion pulse with a bandwidth of 3.2 kHz. With a larger bandwidth, the new pulse maintains the same SAR as the original inversion pulse and also has an improved spectral profile. Images obtained on a phantom, and in-vivo, show improved fat suppression, and reduced ripple artifacts in the slice domain. In addition to improving image quality, the optimized RF pulse may improve the diagnostic ability of STIR with 3D multi spectral imaging.

Imaging and Quantification of Grafted Mesenchymal Stem Cells in Rat Knee Joint

Sergey Magnitsky¹, Jaskanwaljeet Kaur¹, Yu-An Evan Lay², Geetha Mohan², Jinjin Zhang³, Djaudat Idiyatullin³, Michael Garwood³, and Nancy Lane²

¹Radiology, UCSF, San Francisco, CA, United States, ²Center for Musculoskeletal Health, UC Davis, ³Radiology, University of Minnesota

Mesenchymal Stem Cells (MSCs) have high potentials for a treatment of bone diseases. T2*w-MRI in combination with iron labeling of MSCs has shown promising results for the detection of therapeutic cells. However, this method is not applicable for the detection of MSCs in knee joints because both the iron labeled cells and bones produce a hypointense signal. We have shown that the SWIFT sequence overcomes this limitation and generates a distinct and quantifiable signal from iron labeled cells in a knee joint *in vivo*. Proposed protocol opens new opportunities for *in vivo* monitoring of cell therapy of bone disorders.

Echo-planar imaging with the Dynamic Multi-Coil Technique (DYNAMITE-EPI)

Umesh Suryanarayana Rudrapatna¹, Fabian Fluerebrock², Terence W Nixon¹, Robin A de Graaf¹, and Christoph Juchem¹

¹Yale School of Medicine, New Haven, CT, United States, ²RWTH Aachen University, Aachen, Germany

Despite numerous improvements in MRI technology, the fundamental gradient hardware has always been designed to generate linear and orthogonal fields. This mould was broken with the advent of DYNAmic Multi-coil Technique (DYNAMITE), which uses non-linear and non-orthogonal B₀ fields for shimming and imaging. Besides vastly expanding the field shaping possibilities, this new technology also promises faster switching and lower eddy currents. For widespread uptake of this technology, proving its suitability for performing widely used contemporary scans like EPI is a must. In this work we share our results from the first successful implementation of DYNAMITE-EPI.

Computer 74

DTI measurements with exceptional resilience to field heterogeneities in challenging brain regions

Eddy Solomon¹, Gilad Liberman¹, Zhiyong Zhang¹, and Lucio Frydman¹

¹chemical Physics, Weizmann Institute of Science, Rehovot, Israel

This study presents a new diffusion tool based on a novel single-shot 2D MRI method called xSPEN. xSPEN is characterized with unusual resilience to field heterogeneities, but extending it to DTI requires to overcome the strong intrinsic diffusion weighting of this technique. To achieve this we formulated xSPEN's diffusion weighting using a novel, spatially localized b₋ matrix analysis, and devised a novel diffusion-weighting scheme that overcomes xSPEN's original limitations. These methods were numerically validated and applied to new DTI xSPEN sequences with which we mapped diffusion in often unreachable human head regions, including optic nerve and olfactory bulb regions.

How to spend your time? Using multi-echo acquisition versus increasing sampling rate in resting-state fMRI

Daniele Mascali¹, Keith Jamison², Emily Kittelson², Kâmil Uğurbil², Essa Yacoub², Shalom Michaeli², Melissa Terpstra², Federico Giove¹, and Silvia Mangia²

¹Museo Storico della Fisica e Centro Studi e Ricerche "Enrico Fermi", Rome, Italy, ²Center for Magnetic Resonance Research, Dept. of Radiology, University of Minnesota, Minneapolis, MN, United States

High sampling rate is pivotal for differentiating neuronal-related from spurious correlations in resting-state-fMRI (rsfMRI). Acquiring multi-echoes (ME) during an EPI readout increases contrast-to-noise, but it can compromise temporal resolution even when combined with multiband (MB). Therefore, whether MBME-EPI is ultimately beneficial for rsfMRI remains unclear. To address this, we collected data at 3T with 2-mm resolution using MBME-EPI and the human-connectome-project MB-single-echo-EPI. Data were evaluated for spectral amplitude, consistency and specificity. MBME-EPI showed significant gains in all quantities when physiological noise and sampling rate were matched between time-series. However, there was no clear gain when different sampling rates were considered.

Omitting the control condition using self-control super-selective Arterial Spin Labeling to reduce total scan time for flow territory mapping

Thomas Lindner¹, Naomi Larsen¹, Olav Jansen¹, and Michael Helle²

¹Clinic for Radiology and Neuroradiology, University Hospital Schleswig-Holstein, Kiel, Germany, ²Tomographic Imaging Department, Philips Research, Hamburg, Germany

Selective Arterial Spin Labeling (ASL) is established to perform non-contrast enhanced flow territory mapping. In super-selective pCASL only one artery of interest is labeled while the efficiency in contralateral arteries is near zero. To obtain a holistic picture of all brain perfusion territories, the label and control experiments have to be repeated for each artery, prolonging scan time. In this study, it is hypothesized that due to the (almost) negligible signal contribution of non-tagged arteries, selective perfusion images can be calculated from a single scan that is performed without the acquisition of control images.

5042

Computer 78

Imaging inferior alveolar neurovascular bundle using zero echo time magnetic resonance imaging

Chuanchen Zhang¹, Changhu Liang², Chuanying Shi³, Mingzhen Wu³, and Bin Zhang⁴

¹Department of Radiology, Liaocheng People's Hospital, Shandong University, Liaocheng, People's Republic of China, ²Department of Radiology, Shandong Medical imaging research institute, ³Liaocheng People's Hospital, Shandong University, ⁴Liaocheng People's Hospital, Shandong University

The goal of the present study was to evaluate ZTE acquisitions for the inferior alveolar neurovascular bundle (IANB) identification. For this purpose, 15 volunteers were scanned using a standard 3D ZTE sequence with a voxel size of 0.8×0.8×0.8 mm on a 3 Tesla MR unit. Both subjective and objective analyses were performed on all acquired IANB images. The results indicate that ZTE-MRI is feasible for the IANB imaging without the use of contrast material.

Quantitative Measures of Arteriole Flow in Human Perivascular Spaces

Xiaopeng Zong¹ and Weili Lin¹

¹Department of Radiology and Biomedical Research Imaging Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Pulsatility of blood flow in human perivascular spaces may play an important role in clearing metabolic waste from the brain. However, flow measurement within small arterioles using MRI are hampered by the limited spatial resolutions of MRI. We report an approach that can accurately measure flow in sub-voxel tubular structures such as arterioles by combining time of flight and phase contrast MRI. The accuracy of our method were first demonstrated in a flow phantom study. Then, flows of penetrating arterioles were obtained in human subjects. Our results demonstrate the importance of correction of partial volume effects in measuring arteriole flow.

5044

Optimal Control Pulse Design for Contrast in MRI: in vivo applications

Eric Van Reeth¹, H el ene Ratiney¹, Sophie Gaillard¹, Michael Tesch², Olivier Beuf¹, Steffen Glaser², and Dominique Sugny^{3,4}

¹CREATIS - CNRS UMR 5220 - INSERM U1206 - Universit  Lyon 1 - INSA Lyon - Universit  Jean Monnet Saint-Etienne, Villeurbanne, France, ²Department of Chemistry, Technische Universit t M nchen, Munich, Germany, ³Laboratoire Interdisciplinaire Carnot de Bourgogne, Dijon, France, ⁴Technische Universit t M nchen Institute for Advanced Study, Munich, Germany

Optimal control RF pulse design has recently been proposed to address the optimization of image contrast in MRI - in order to explore the theoretical contrast bound of a given imaged system. Their use has recently been validated on a real MRI scanner to contrast various *in vitro* samples. This abstract extends these results to *in vivo* applications, and shows that contrasts obtained with standard weighting strategies on rat and mouse brains can be improved or inverted. This demonstrates both the interest and flexibility that one can get when using optimal contrast pulses for *in vitro* and *in vivo* applications.

Computer 83

Bloch-Siegert Phase-Encoded MRI with a Single RF Coil and Frequency-Swept Pulses

Christopher J Hasselwander¹ and William A Grissom¹

¹Biomedical Engineering, Vanderbilt University, Nashville, TN, United States

RF encoding using the Bloch-Siegert shift has the potential to replace conventional gradient encoding with cheaper RF gradients, and can directly replace gradient pulsing in common MRI sequences. However, current implementations require large frequency offsets to prevent on-resonance excitation, which subsequently requires high RF power for encoding as well as separate imaging and encoding RF coils. Here we show that frequency-swept encoding RF pulses enable the use of a single RF coil for imaging and encoding since the frequency offset can be brought much closer to resonance.

Simultaneous interleaved blip up/down readout for dynamic off-resonance correction in functional EPI

Benjamin Zahneisen¹, Murat Aksoy¹, and Julian Maclaren¹

¹Stanford University, Stanford, CA, United States

Motion and geometric distortions of EPI acquisitions remain challenging as motion during an fMRI scan affects the stability of the time series in two ways: Rigid motion displaces voxels by "moving" the spins. A change in head orientation and the complex interplay of external and internal susceptibility differences lead to a change in the off-resonance field. In combination with an EPI readout this change in off-resonance field leads to an "apparent" voxel displacement. Here, we propose the simultaneous acquisition of a blip-down navigator with the original blip-up host-EPI sequence which is used to derive a snapshot of dynamic off-resonance changes.

Computer 87

Using the inflow effect to determine velocity in the carotid artery: comparison with phase contrast velocity mapping

Neville D Gai¹ and John A Butman¹¹Radiology & Imaging Sciences, NIH Clinical Center, Bethesda, MD, United States

Phase contrast (PC) imaging is commonly employed for mapping velocities in cerebral arteries. This requires a dedicated sequence along with acquisition of two sets of image data. In addition, PC imaging can be compromised by residual eddy currents, motion, selection of velocity encoding value (VENC) and imaging plane in relation to the vessel. In this work, a magnitude based method exploiting the inflow effect was employed to determine velocity in the carotid arteries. A standard 3D T1w SPGR sequence was used eschewing the need for a dedicated sequence. By measuring signal in ROIs at two locations of the artery and jugular vein, velocity independent of B1 inhomogeneity can be derived. The effect of B1+ field was also taken into account. It was shown that the velocity estimated with this technique shows significant correlation with PC based velocity while showing no significant differences in the right and left CAs in 12 volunteers.

Magnetic Resonance Imaging under Highly Inhomogeneous B₀ Fields using Missing-Pulse Steady-State Free Precession (MP-SSFP)Naoharu Kobayashi¹, Djaudat Idiyatullin¹, Gregor Adriany¹, and Michael Garwood¹¹Center for Magnetic Resonance Research, Department of Radiology, University of Minnesota, Minneapolis, MN, United States

In vivo human brain imaging under highly inhomogeneous B₀ field of 250 kHz off-resonance variation over 20 cm is demonstrated. The B₀ field inhomogeneity was generated by mounting a head gradient coil at 36 cm off the isocenter of a 90-cm 4T magnet. Brain imaging was performed with 3D missing-pulse steady-state free precession using the inhomogeneous field gradient for spatial (readout) encoding. Frequency-modulated pulses were employed to excite the widely distributed spin frequencies in the inhomogeneous field with easily achievable RF peak power (~1 kW). By providing combined T₁, T₂, and high diffusion weighting, images with clear delineation of brain anatomy were produced.

A Rapid Hybrid Spiral Spin-Echo Technique for Simultaneous Multi-Contrast Fat-Water Imaging

Zhiqiang Li¹, Dinghui Wang¹, and James G Pipe¹¹Imaging Research, Barrow Neurological Institute, Phoenix, AZ, United States

In the conventional MR setting, each contrast is typically acquired with a different scan/sequence, often resulting in long scan time and inter-scan misregistration. Simultaneous multi-contrast imaging has advantages such as good registration, reduced scan time, etc. In this project we propose a hybrid spiral SE technique for simultaneous T₁, T₂, and PD imaging, with fast scan speed and improved image quality.

Improved image-based navigators (iNAVs) for free-breathing cine DENSE using principle component analysis to separate the stimulated echo and T₁ relaxation signalsXiaoying Cai¹, Yang Yang¹, Xiaodong Zhong^{2,3}, Daniel S Weller⁴, Michael Salerno^{1,5,6}, and Frederick H Epstein^{1,5}

¹Biomedical Engineering, University of Virginia, Charlottesville, VA, United States, ²MR R&D Collaborations, Siemens Healthcare, Atlanta, GA, United States, ³Department of Radiology and Imaging Sciences, Emory University, Atlanta, GA, ⁴Electrical and Computer Engineering, University of Virginia, Charlottesville, VA, United States, ⁵Radiology, University of Virginia, ⁶Medicine, University of Virginia

Cine displacement encoding with stimulated echoes (DENSE) is an accurate strain imaging technique that generally requires breath-holding. We have recently developed a free-breathing method with image-based navigators (iNAVs) that makes use of the localized signal generation property of stimulated echoes (STE) to facilitate the estimation of heart motion due to respiration. However the non-localized echo due to T₁ relaxation presents challenges. We propose to use principle component analysis (PCA) to separate the STE and T₁-relaxation echo signals and improve the accuracy of motion estimation with iNAVs for free-breathing cine DENSE.

A Method of Fat Saturation with Better Transmit Field Inhomogeneity Immunity

Xiaocheng Wei¹ and Yongchuan Lai²

¹MR Research China, GE Healthcare, Beijing, People's Republic of China, ²MR Engineering, GE Healthcare, Beijing, People's Republic of China

Discrimination between signals from fat and water is of great importance in clinical practice. Chemical saturation, the most widely used fat suppression method, has degraded performance in an in-homogeneity transmit field, and may jeopardize the diagnosis effectiveness. In this abstract, we proposed an improved fat saturation method employing multiple chemical saturation segments. Phantom and volunteer evaluation results show that new method has much less residual lipid signal and can achieve more uniform lipid saturation over big field of view under inhomogeneity condition. Which support the conclusion that proposed method has superior transmit field inhomogeneity immunity.

SUPER: a novel acquisition and reconstruction strategy for improved efficiency and resolution in parameter mapping

Chenxi Hu¹ and Dana Peters¹¹Yale University, New Haven, CT, United States

Standard parameter mapping methods such as T₁ and T₂ mapping suffer from long scan time and low resolution due to the need to sample multiple images along the relaxation curve. Here we propose a novel acquisition and reconstruction strategy to improve efficiency by undersampling each k-space frame in the phase-encoding direction. By shifting the undersampling pattern circularly in each time frame, the relaxation signal at spatially distinct voxels is modulated and combined into a single signal, which can be used to reconstruct the parameters by solving a small-size nonlinear equation. This technique is especially suitable for applications where multiple T₁s or T₂s are needed, and can improve either resolution or acquisition time.

Computer 93

[2D acquisition mode for T1 and T2 estimation using an ellipse-fitting approach on phase cycled bSSFP data](#)Yulia Shcherbakova¹, Cornelis A.T. van den Berg², Pim T.S. Borman¹, Chrit T.W. Moonen¹, and Lambertus W. Bartels³

¹Center for Imaging Sciences/Imaging Division, University Medical Center Utrecht, Utrecht, Netherlands, ²Dept. of Radiotherapy/Imaging Division, University Medical Center Utrecht, Utrecht, Netherlands, ³Image Sciences Institute/dept. of Radiology, University Medical Center Utrecht, Utrecht, Netherlands

The ellipse fitting approach for simultaneous estimation of the relaxation times T_1 and T_2 from phase-cycled balanced steady-state free precession (PC-bSSFP) has been so far limited to the 3D acquisition mode due to sensitivity to slice profile imperfections. In this work we present the results of a 2D approach which is based on a RF excitation pulse optimization. This minimally affects the ellipse fitting leading to minimal corruption of T_1 and T_2 quantification from 2D PC-bSSFP data.

[Fast and robust magnetic resonance fingerprinting with Cartesian sampling using random RF and gradient spoilers to reset the longitudinal and transverse magnetization](#)Daiki Tamada¹, Takashi Watanabe¹, Tomoyuki Takeguchi¹, and Hitoshi Kanazawa²

¹Toshiba Corporation, Kawasaki, Japan, ²Toshiba Medical Systems Corporation, Otawara, Japan

A prepulse for resetting longitudinal and transverse magnetization is proposed in order to accelerate magnetic resonance fingerprinting (MRF) with Cartesian sampling. A pulse sequence was developed based on a steady-state free precession sequence in which the prepulse consists of a set of radio frequency (RF) pulses and gradient spoilers. Simulation and experimental results demonstrated that the prepulse enables fast MRF in the presence of additional sequence modules, such as respiration triggering.

[Relaxometry via steady-state ring-locked trajectories](#)James C Korte¹, Bahman Tahayori², Peter M Farrell¹, Stephen M Moore³, and Leigh A Johnston¹

¹Dept. Electrical & Electronic Engineering, University of Melbourne, Melbourne, Australia, ²Dept. Electrical and Computer Systems Engineering, Monash University, Melbourne, Australia, ³IBM Research, Melbourne, Australia

It is known that steady-state ring-locked trajectories are formed on an elliptical manifold under a constant amplitude and constant frequency excitation envelope. Here we demonstrate that the excitation envelope can be expressed in terms of the spin-system parameters and a target steady-state trajectory, providing control of the magnetisation on the steady-state ellipsoid when spin-system parameters, such as the relaxation constants, are known. Conversely, we exploit this relationship between excitation parameters and unknown relaxation constants to develop a volume relaxometry technique, which can potentially be extended to relaxation mapping due to the elliptical nature of balanced SSFP.

Computer 96

[Magnetic Resonance Fingerprinting using phase cycling bSSFP \(phc-MRF\) in presence of B0 inhomogeneity.](#)Simone Coppo¹, Bhairav Bipin Mehta¹, Dan Ma¹, Yun Jiang¹, and Mark Alan Griswold¹

¹Radiology Department, Case Western Reserve University, Cleveland, OH, United States

Magnetic Resonance Fingerprinting (MRF) is a newly developed approach for accurate and efficient multi parameter mapping. This work proposes a balanced steady state free precession (bSSFP) based MRF framework which introduces different phase cycling (phc-MRF) to compensate for banding artifact induced by B_0 inhomogeneity. The phc-MRF was tested in both phantoms and in vivo. The preliminary results show the robustness of the phc-MRF to banding artifacts while maintaining the precision of parameter estimation and B_0 sensitivity.

[Semi-automated identification of Substantia Nigra in healthy controls and patients with Parkinson's Disease: a feasibility study using MP2RAGE](#)Maria Eugenia Caligiuri¹, Gaetano Barbagallo², Tobias Kober³, Umberto Sabatini⁴, Aldo Quattrone^{1,2}, and Andrea Cherubini¹

¹Neuroimaging Unit, Institute of Bioimaging and Molecular Physiology (IBFM-CNR), Catanzaro, Italy, ²Institute of Neurology, University Magna Graecia, Catanzaro, Italy, ³Healthcare Sector IM&WS S, Siemens Schweiz AG, Renens, Switzerland, ⁴Institute of Neuroradiology, University Magna Graecia, Catanzaro, Italy

Reliable in vivo assessment of human substantia nigra (SN) requires highly trained operators and different MRI sequences. Advanced techniques have recently facilitated SN identification, but their acquisition in routine clinical practice may not be feasible. MP2RAGE allows for quantitative T_1 mapping with an acceptable acquisition time (< 10 minutes). Moreover, SN can be seen on T_1 maps, but not on standard MPRAGE. In this study, we tested the feasibility of semi-automated SN identification on MP2RAGE-derived T_1 maps by using a thresholding approach, and compared SN volume and T_1 values between healthy controls and patients with Parkinson's disease.

[Myelin water atlas for cervical spinal cord: A template for spinal cord pathway myelin microstructure](#)Hanwen Liu^{1,2}, Emil Ljungberg³, Erin MacMillan³, Laura Barlow⁴, Shannon Kolind³, John Kramer^{2,5}, and Cornelia Laule^{2,6,7}

¹Physics, University of British Columbia, Vancouver, BC, Canada, ²International Collaboration on Repair Discoveries, Vancouver, BC, Canada, ³Medicine, University of British Columbia, Vancouver, BC, Canada, ⁴UBC Hospital, University of British Columbia, Vancouver, BC, Canada, ⁵Kinesiology, University of British Columbia, Vancouver, BC, Canada, ⁶Radiology, University of British Columbia, Vancouver, BC, Canada, ⁷Pathology and Laboratory Medicine, University of British Columbia, BC, Canada

In-vivo microstructural information of myelin in the spinal cord is desirable for studying spinal cord injury and neurodegenerative diseases. We used myelin water imaging combine with Spinal Cord Toolbox to create a standard microstructure template specific to myelin content, so-called myelin water atlas, for healthy cervical spinal cord. The resulting atlas is able to distinguish myelin content in 7 different spinal cord pathways and agrees with well-known anatomical characteristics. Our work shows the potential of using a myelin water atlas as a microstructure reference to visualize demyelination in spinal cord injuries or diseases.

Visualization of Cardiac and Respiratory Pressure Gradient of Cerebrospinal Fluid Based on Asynchronous Two-Dimensional Phase Contrast Imaging

Saeko Sunohara¹, Satoshi Yatsushiro², Mitsunori Matsumae³, and Kagayaki Kuroda^{1,2}

¹Graduate School of Engineering, Tokai University, Hiratsuka, Kanagawa, Japan, ²Graduate School of Science and Technology, Tokai University, Hiratsuka, Kanagawa, Japan, ³Department of Neurosurgery, Tokai University School of Medicine, Isehara, Kanagawa, Japan

To visualize the distribution of the pressure gradients of the cardiac- and respiratory-driven cerebrospinal fluid (CSF), asynchronous two-dimensional phase-contrast velocity imaging was performed in 9 healthy subjects. The pressure gradients were calculated by the Navier–Stokes equations after the total CSF motion was classified into either cardiac or the respiratory components in the frequency domain. In the prone position, the pressure gradients in the caudal-to-cranial direction were 14.9 ± 3.17 Pa/m for cardiac components and 1.28 ± 0.46 Pa/m for respiratory components; the cardiac pressure gradient was also significantly larger than the respiratory pressure gradient in other regions.

On the profile ordering of Golden Angle radial Simultaneous Multi-Slice imaging

Pim Borman¹, Rob H.N. Tijssen¹, Bas Raaymakers¹, Chrit Moonen², and Clemens Bos²

¹Radiotherapy, UMC Utrecht, Utrecht, Netherlands, ²Imaging Division, UMC Utrecht, Utrecht, Netherlands

Golden angle radial sampling allows for flexible sliding window reconstructions while minimizing motion sensitivity and undersampling artifacts. Simultaneous MultiSlice (SMS) can be used to increase the spatial coverage without decreasing the framerate. Here we show that the golden angle profile ordering is in principle not compatible with the in-plane phase cycling scheme required by SMS. It follows that these are only compatible for a certain number of spokes, namely when the number of spokes is part of the Fibonacci sequence **and** the SMS factor is a divisor of this number.

Computer 101

Non-rigid Groupwise Registration for Intravoxel Incoherent Motion Imaging of the Heart

Valery Vishnevskiy¹, Georg Spinner¹, Christian Stoeck¹, Constantin von Deuster¹, and Sebastian Kozerke¹

¹Institute for Biomedical Engineering, ETH Zurich, Zurich, Switzerland

Intravoxel Incoherent Motion (IVIM) imaging is an attractive approach for contrast-agent free in vivo perfusion measurement in the heart. Since the data is acquired during free breathing, nonrigid respiratory motion is considerable and needs to be corrected before estimation of IVIM parameters. In order to provide accurate image registration, an approach with parametric total variation regularization of displacements and low-rank structure of aligned images stack is presented. The proposed method allows for robust IVIM parameter estimation and improves mean squared residuals of the IVIM model by 24% on average compared to state-of-the-art non-rigid registration methods.

5066

Computer 102

A supervised automated segmentation strategy for renal DCE-MR images

Wenjian Huang¹, Hao Li^{1,2}, Jue Zhang^{1,3}, Xiaoying Wang^{1,4}, and Jing Fang^{1,3}

¹Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, People's Republic of China, ²Department of Radiology, University of Cambridge, United Kingdom, ³College of Engineering, Peking University, Beijing, People's Republic of China, ⁴Department of Radiology, Peking University First Hospital, Beijing, People's Republic of China

A supervised DCE-MR images classification strategy is proposed in this study. First, the training set was obtained by an automated seeds extraction procedure. Subsequently, support vector machine (SVM) and random walk algorithms were employed as two separate classification approaches to achieve image segmentations, respectively. The automated segmentations and a repeated manual segmentation were compared quantitatively with a reference manual segmentation. The average similarity indexes for SVM, random walker and repeated manual segmentation were 0.78, 0.76 and 0.72, respectively. The results indicate that the proposed strategy yield a satisfied similarity with manual segmentation and is more stable than the manual segmentation.

Computer 103

Improving Accuracy in MR Fingerprinting by Off-Resonance Deblurring

Peter Koken¹, Thomas Amthor¹, Mariya Doneva¹, Holger Eggers¹, Karsten Sommer¹, Jakob Meineke¹, and Peter Börner^{1,2}

¹Philips Research Europe, Hamburg, Germany, ²Dept. Radiology, LUMC, Leiden, Netherlands

Efficient, highly under-sampled spiral acquisition is preferred in magnetic resonance fingerprinting (MRF). However, although the spiral is very efficient in terms of sampling, it is sensitive to all kinds of off-resonance effects resulting in signal blurring. This effect leads to geometric distortion and matching errors, reducing accuracy significantly. To overcome these limitations, the present work proposes to combine spiral-based MRF with field map-based deblurring, e.g. by conjugate phase reconstruction (CPR). The basic feasibility of this approach for under-sampled MRF is shown in phantom and in-vivo experiments, underlining the effectiveness of this simple correction approach paving the way for even more efficient MRF sampling.

5068

Computer 104 Partial volume effect correction for surface-based cortical mapping

Camille Van Assel¹, Gabriel Mangeat^{1,2}, Benjamin De Leener¹, Nikola Stikov^{1,3}, Caterina Mainero^{2,4}, and Julien Cohen-Adad^{1,5}

¹NeuroPoly Lab, Institute of Biomedical Engineering, Polytechnique Montreal, Montreal, QC, Canada, ²Athinoula A. Martinos Center for Biomedical Imaging, Charlestown, MA, United States, ³Montreal Health Institute, Montreal, QC, Canada, ⁴Harvard Medical School, Boston, MA, United States, ⁵Functional Neuroimaging Unit, CRIUGM, Université de Montréal, Montreal, QC, Canada

Partial Volume Effect (PVE) hampers the accuracy of studies aiming at mapping MRI signal in the cortex due to the close proximity of adjacent white matter (WM) and cerebrospinal fluid (CSF). The proposed framework addresses this issue by disentangling the various sources of MRI signal within each voxel, assuming three classes (WM, gray matter, CSF) within a small neighbourhood. MRI scans of 17 healthy subjects suggest robust estimations of PVE, allowing accurate extraction of MRI metrics using surface-based analysis. This method can be particularly useful for probing pathology in outer or inner cortical layers, which are subject to strong PVE with adjacent CSF or WM.

¹Clinical Research Imaging Centre, The University of Edinburgh, Edinburgh, United Kingdom, ²MRC Centre for Inflammation Research, The University of Edinburgh, Edinburgh, United Kingdom, ³Anaesthesia, Critical Care and Pain Medicine, The University of Edinburgh, Edinburgh, United Kingdom, ⁴The Mentholatum Company Ltd., East Kilbride, United Kingdom

Muscle wasting is common during critical illness. In this study, thigh muscles of previously mobile patients surviving an episode of severe critical illness were imaged by Magnetic Resonance Imaging (MRI) during convalescence and compared to healthy controls. We present preliminary findings of the first clinical study using Magnetic Resonance Elastography (MRE) to measure muscle stiffness (kPa) and muscle cross-sectional area (mm²) for Intensive Care Unit (ICU) patients. A statistically significant reduction in muscle area and muscle stiffness in patients was found when compared to the healthy control group. There was a significant cross-sectional muscle area increase following ICU patient discharge.

5070

Computer 106 Improved Denoising of Dynamic Arterial Spin Labeling with Infimal Convolution of Total Generalized Variation Functionals (ICTGV)

Matthias Schloegl¹, Stefan Spann¹, Christoph Aigner¹, Martin Holler², Kristian Bredies², and Rudolf Stollberger¹

¹Institute of Medical Engineering, Graz University of Technology, Graz, Austria, ²Institute of Mathematics and Scientific Computing, University of Graz, Austria

Dynamic arterial spin labeling MRI provides important quantitative information about blood arrival time and perfusion. However, the inherently low signal-to-noise ratio requires repeated measurements to achieve a reasonable image quality. This leads to long acquisition times and hence increases the risk of motion artifacts, which impedes clinical applicability. To overcome this limitation we propose to reconstruct the dynamic ASL data employing ICTGV regularization from a reduced number of averages. The performance of the method is evaluated on synthetic and in-vivo ASL data.

5071

Computer 107 Fast Non-iterative Image Reconstruction for O-space Imaging

Maolin Qiu¹, Yuqing Wan¹, and R. Todd Constable¹

¹Yale School of Medicine, New Haven, CT, United States

MRI with non-linear spatial encoding magnetic fields (SEM) can provide high quality MR images, but these images are usually calculated using iterative optimization procedures. Such reconstruction methods can take a long time to converge, and the results may depend on the initial iteration parameters. We propose a fast, non-iterative image reconstruction method for O-space imaging based on the local K-space and local SEMs and demonstrate its effectiveness for image reconstruction of nonlinear O-space imaging data.

5072

Computer 108 Wavelet based Texture Analysis of Liver Fibrosis in Delayed Phase Gadolinium-Enhanced T1-weighted in vivo Images

Lavanya Umapathy¹, Jonathan Brand², Jean-Philippe Galons³, Lars Furenlid^{2,3}, Diego Martin³, Maria Altbach³, and Ali Bilgin^{1,4}

¹Electrical and Computer Engineering, University of Arizona, Tucson, AZ, United States, ²College of Optical Sciences, University of Arizona, Tucson, AZ, United States, ³Medical Imaging, University of Arizona, Tucson, AZ, United States, ⁴Biomedical Engineering, University of Arizona, Tucson, AZ, United States

Non-invasive imaging techniques that can identify early structural changes due to fibrosis in vivo are of high clinical importance. In this work, a five-level wavelet decomposition of biopsy confirmed normal and fibrotic ex vivo liver tissues is performed and histogram-based features are extracted from the wavelet subbands. A linear classifier is trained using the top 10 features and applied to classify liver fibrosis in Gadolinium-enhanced delayed phase T1-weighted in vivo images. The results show that normal samples yield low posterior probabilities for fibrosis whereas these values are very high for fibrotic samples.

5073

Computer 109 An alternative to phase image-based Magnetic Resonance Elastography (MRE) using k-space data processing

Nadège Corbin^{1,2}, Elodie breton¹, Michel de Mathelin¹, and Jonathan Vappou¹¹*Cube, University of Strasbourg, CNRS, IHU Strasbourg, Strasbourg, France,* ²*Wellcome Trust Centre for Neuroimaging, UCL Institute of Neurology, London, United Kingdom*

MR Elastography (MRE) requires substantial data processing involving phase image reconstruction, wave enhancement and inverse problem solving. The objective of this study is to propose an alternative reconstruction method based on direct k-space data processing, particularly adapted to applications requiring fast MRE measurements such as the monitoring of elasticity changes. Elastograms are directly reconstructed from raw MR data without prior phase image reconstruction, circumventing thereby the delicate step of phase unwrapping. The k-space MRE method shows promising results by providing elasticity values similar to the ones obtained with conventional MRE in phantoms and in vivo in porcine liver.

5074

Computer 110 Texture Analysis for Evaluating Image Registration

Vikas Kotari¹ and Vasiliki N Ikonomidou²¹*Electrical Engineering, George Mason University, Fairfax, VA, United States,* ²*Bioengineering, George Mason University*

Accurate image registration is essential for both cross-sectional and longitudinal MR studies. In longitudinal studies aligning same contrast intra-subject images, which are the focus of our work, registration is assumed to be a rigid body problem. This assumption is questionable due to global and local changes in brain volume either due to hydration or atrophy. Consequently, misregistration at the voxel level may occur in these studies, which might lead to subject data being discarded. This misregistration is evident particularly around the cortex. Visual inspection of images is used to determine registration accuracy. While this approach is suitable for assessing alignment of landmark structures, it fails to capture the millimetric or sub-millimetric misregistrations. Automatic metrics can precisely estimate the overall performance of a given registration algorithm by employing an evaluation database. However, to estimate the registration accuracy of a given pair of images, such metrics are unsuitable. In this work we propose texture analysis of a subtraction image to evaluate the registration accuracy of a given pair of same contrast, intra-subject images. Once registered, images are intensity normalized, blurred and subtracted. In the event of registration errors, or violation of the rigid body assumption, the subtraction images have artifacts. The texture features of these artifacts are different from the artifact-free (clean) areas of the subtraction images. Using a texture-based classifier, artifact areas in the subtraction images that indicate failed registration are identified. In addition to determining if the registration has failed, our approach can identify the specific locations of misregistration, which can be corrected, leading to a more inclusive subject data.

5075

Computer 111 Dynamically Phase-Cycled bSSFP Cardiac Cine in a Single Breathhold with Phase-Cycle Consistency Regularization

Corey Allan Baron¹, Anjali Datta¹, and Dwight G Nishimura¹¹*Stanford University, Stanford, CA, United States*

At high field strengths, cardiac cine acquisitions acquired with balanced SSFP can suffer from banding artifacts. To mitigate this issue, dynamically phase-cycled cardiac cine was acquired in a single breathhold with undersampling rates of 4 and 6, and images were reconstructed with a phase-cycle banding profile regularization that exploits redundancy between phase-cycles.

5076

Computer 112 Myelin Water Fraction Estimation from Optimized Steady-State Sequences using Kernel Ridge Regression

Gopal Nataraj¹, Jon-Fredrik Nielsen², and Jeffrey A. Fessler¹¹*Electrical Engineering and Computer Science, University of Michigan, Ann Arbor, MI, United States,* ²*Biomedical Engineering, University of Michigan, Ann Arbor, MI, United States*

This work introduces a new framework for myelin water fraction (MWF) estimation. We use a novel scan design approach to construct a sequence of fast steady-state sequences and optimize corresponding flip angles and repetition times for precise MWF estimation. We quantify MWF and five other parameters per voxel using a novel method based on kernel ridge regression. We obtain MWF maps in vivo that are comparable to those reported in literature, with possibly shorter overall scan time.

5077

Computer 113 A T2 Template Map from a Healthy Cohort to Identify Localized Anomalies in Single Subjects

Tom Hilbert^{1,2,3}, Alexis Roche^{1,2,3}, Cristina Granziera^{4,5}, Guillaume Bonnier⁶, Kieran O'Brien^{6,7}, Tony Stöcker⁸, Pavel Falkovskiy^{1,2,3}, Reto Meuli², Jean-Philippe Thiran^{2,3}, Gunnar Krueger^{2,3,9}, and Tobias Kober^{1,2,3}¹*Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, Switzerland,* ²*Department of Radiology, University Hospital (CHUV), Lausanne, Switzerland,* ³*LTS5, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland,* ⁴*Neuroimmunology Unit, Neurology, Department of Clinical Neurosciences, Centre Hospitalier Universitaire Vaudois (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland,* ⁵*Martinos Center for Biomedical Imaging, Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States,* ⁶*Center for Advanced Imaging, the University of Queensland, Brisbane, Australia,* ⁷*Siemens Healthcare Pty Ltd, Brisbane, Australia,* ⁸*German Center for Neurodegenerative Diseases, Bonn, Germany,* ⁹*Siemens Medical Solutions USA, Inc., Boston, MA, United States*

We construct a database of normal T2 values by spatially normalizing quantitative maps from healthy subjects into a common space. A low standard deviation across all subjects demonstrates good reproducibility of the T2 values in white matter and deep grey matter. Additionally we adopt a standard voxel-based procedure that compares the quantitative T2 map of a patient to the database and test it on three multiple sclerosis datasets. The obtained z-score maps show that white matter lesions can be detected in the limits of the available resolution and the applied smoothing.

5078

Computer 114 Temperature Mapping of Fluorinated (19F) Gas in a Cool Down Experiment

Tobias J. Hoh^{1,2}, Eduardo Coello^{1,2}, Jorge Carretero Benignos², Axel Haase¹, and Rolf F. Schulte²

¹Technische Universität München, Munich, Germany, ²GE Global Research, Munich, Germany

Magnetic resonance imaging (MRI) temperature mapping of gases is challenging due to limited sensitivity. In this proof of concept study, proton thermometry methods from tissue temperature monitoring were transferred to ¹⁹F gas MRI.

A phase-dependent ¹⁹F resonance frequency shift temperature mapping is proposed for fluorinated gas at 3T based on a spiral readout to overcome limitations of ultra-short relaxation times.

This work demonstrates the feasibility of 2D thermometry in a canonical setup with inert fluorinated gases.

Optimization of brain extraction increases global cortical thickness accuracy

Antonio Carlos da Silva Senra Filho¹, Gareth J. Barker², Luiz Otávio Murta Junior¹, and Flavio Dell'Acqua³

¹Department of Computing and Mathematics, University of Sao Paulo, Ribeirao Preto, Brazil, ²Department of Neuroimaging, King's College London, London, United Kingdom, ³Department of Forensic & Neurodevelopmental Sciences, King's College London, London, United Kingdom

Reconstruction of the cortical surface is of great importance as a biomarker for many brain diseases, and in recent years a number of advances in image processing and analysis have been made in the cortical reconstruction process. However, despite the scientific community employing a range of advanced surface reconstruction algorithms in order to improve quantitative accuracy, cortical thickness measurement is still a challenge. Here, we address the question of whether a better brain extraction procedure can improve the cortical surface reconstruction. Our analyses suggest that a more accurate brain mask directly affects the global cortical thickness estimate, reducing its quantitative uncertainty.

[Test-retest repeatability of human speech biomarkers from static and real-time dynamic magnetic resonance imaging](#)Johannes Toger¹, Tanner Sorensen¹, Krishna Somandepalli¹, Asterios Toutios¹, Sajan Goud Lingala¹, Shrikanth Narayanan¹, and Krishna S Nayak¹¹Ming Hsieh Department of Electrical Engineering, University of Southern California, Los Angeles, CA, United States

This study presents a test-retest repeatability framework for quantitative speech biomarkers from static MRI and real-time MRI (RT-MRI), and applies the framework to healthy volunteers (n=8). Repeatability was quantified using intraclass correlation coefficient (ICC) and mean within-subject standard deviation (σ_e). Inter-study agreement was strong to very strong for static anatomical biomarkers, (ICC: min/median/max 0.71/0.89/0.98, σ_e : min/median/max 0.90/2.20/6.72 mm), poor to very strong for dynamic RT-MRI biomarkers of articulator motion range (ICC: 0.26/0.75/0.90, σ_e : 1.6/2.5/3.6 mm) and poor to very strong for velocity (ICC: 0.26/0.56/0.93, σ_e : 2.2/4.4/16.7 cm/s). The introduced framework can be used to guide future development of speech biomarkers.

[Slipped Capital Femoral Epiphysis Causes Early Cartilage Degeneration in Young Adults – an 11 year follow-up study with dGEMRIC](#)Jakob Örtengren¹, Pernilla Peterson², Jonas Svensson³, and Carl Johan Tiderius¹¹Dept of Orthopedics, Skane University Hospital, Lund, Sweden, ²Dept. of Translational Medicine, Lund University, Malmö, Sweden, ³Dept. of Medical Imaging and Physiology, Skane University Hospital, Lund, Sweden

The longitudinal effects of Slipped Capital Femoral Epiphysis (SCFE) on hip cartilage integrity and hip function are poorly understood. In this study, 44 hips were evaluated with delayed Gadolinium-enhanced MRI of cartilage (dGEMRIC) in average 11 years after SCFE. A low dGEMRIC index was detected in SCFE hips compared to unaffected hips, with gradually lower dGEMRIC index anteriorly in the hip joint. Furthermore, a low dGEMRIC index correlated both with impaired hip function and femoroacetabular impingement (FAI), which further strengthens the theory of FAI as a mediator of osteoarthritis after SCFE.

[Revisiting the experimental base of compositional biomarkers: A meta-analysis study](#)Jose G Raya¹, Amparo Ruiz¹, and Uran Ferizi¹¹Department of Radiology, New York University School of Medicine, New York, NY, United States

We aim to perform a meta-analysis of the corpus of experimental results accumulated for compositional MRI biomarkers of articular cartilage used in clinical studies. We summarized the data according to the statistical evidence that is reported. We report the correlation of MRI parameters with composition, the ability of MRI parameters to detect group differences between healthy and degraded cartilage, and the ability of MRI to detect cartilage damage.

5087

Computer 3

[Changes in collagen and proteoglycan in cartilage with OA severity](#)Jose G Raya¹, Uran Ferizi¹, Amparo Ruiz¹, Steven B Abramson², Jenny Bencardino¹, and Svetlana Krasnokutsky Samuels²¹Department of Radiology, New York University School of Medicine, New York, NY, United States, ²Department of Medicine, New York University School of Medicine, New York, NY, United States

The objective of this work was to investigate differences in cartilage matrix composition and structure across subjects with different stages of OA severity and test if the changes in the collagen network are concomitant or subsequent to the changes in proteoglycan.

Computer 4

[Magnetic resonance imaging of the zone of calcified cartilage \(ZCC\) in the knee joint using 3D UTE Cones sequences](#)Yinghua Zhao^{1,2}, Yajun Ma¹, Michael Carl³, Xing Lu¹, Yanchun zhu¹, Eric Y Chang^{1,4}, and Jiang Du¹¹University of California, San Diego, San Diego, CA, United States, ²Radiology, Third Affiliated Hospital of Southern Medical University (Academy of Orthopedics · Guangdong Province), Guangzhou, People's Republic of China, ³GE Healthcare, San Diego, CA, United States, ⁴Radiology Service, VA San Diego Healthcare System, San Diego, CA, United States

The zone of calcified cartilage (ZCC) is a thin layer between articular cartilage and bone. The ZCC plays an important role in the pathogenesis of osteoarthritis (OA) but has never been imaged in vivo with magnetic resonance (MR) imaging techniques. In this study we aimed to investigate the feasibility of direct imaging of the ZCC in healthy volunteers using a three dimensional (3D) ultrashort echo time (UTE) Cones sequence on a clinical whole body 3T scanner.

[Knee cartilage T₂ mapping with T₂-prepared isotropic 3D GRE has equivalent precision and higher accuracy compared to multi-slice TSE in volunteers and patients at 3T](#)Roberto Colotti¹, Patrick Omoumi¹, Gabriele Bonanno^{1,2,3}, Jean-Baptiste Ledoux¹, and Ruud B. van Heeswijk¹

¹Department of Radiology, University Hospital (CHUV) and University of Lausanne (UNIL), Lausanne, Switzerland, ²Division of Cardiology, Department of Medicine, Johns Hopkins University, Baltimore, United States, ³Division of MR Research, Department of Radiology, Johns Hopkins University, Baltimore, United States

The goal of this study was to compare the precision and accuracy of a novel isotropic 3D T₂-prepared gradient-echo T₂ mapping technique (Iso3DGRE) with the clinical standard 2D multi-slice turbo spin-echo (MS-TSE) for T₂ mapping of knee cartilage at 3T. A phantom study was performed to determine the accuracy of both techniques against the reference standard spin echo (SE). T₂ mapping of knee cartilage was then performed in 13 healthy volunteers and 5 patients with late-stage osteoarthritis. Compared to MS-TSE, Iso3DGRE T₂ mapping resulted in T₂ values with equivalent precision and slightly higher accuracy at a higher spatial resolution.

[GRAPPATINI put to use: How MSK applications benefit from highly undersampled T2 mapping and synthetic contrasts](#)

Marcus Raudner¹, Tom Hilbert^{2,3,4}, Tobias Kober^{2,3,4}, Vladimir Juras¹, Ewald Moser⁵, Claudia Kronnerwetter¹, David Stelzeneder⁶, and Siegfried Trattnig¹

¹High Field MR Centre, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria, ²Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, Switzerland, ³Department of Radiology, University Hospital (CHUV), Lausanne, Switzerland, ⁴LTS5, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ⁵Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, Austria, ⁶Department of Orthopaedics, Medical University of Vienna, Vienna, Austria

The quantitative measurement of the T₂ relaxation time has been shown to be a useful tool for radiological diagnosis. However, the use of quantitative MRI (qMRI) in clinical routine is often hindered due to long acquisition times. Here, we assess T₂ parameters in the lumbar and cervical spine as well as the knee using GRAPPATINI, a model-based accelerated T₂ mapping sequence. Additionally, synthetic T₂-weighted (T₂w) images are derived from the quantitative maps. The T₂ maps and synthetic T₂w images are compared to conventional T₂w and T₂ mapping sequences, yielding an overall 5.8-fold time-saving.

[High-resolution In-vivo Mapping of the Proteoglycan-bound Water Fraction in Articular Cartilage of the Human Knee Joint](#)

Mustapha Bouhrara¹, David A. Reiter¹, Kyle W. Sexton¹, Christopher M. Bergeron¹, Linda M. Zukley¹, and Richard G. Spencer¹

¹National Institute on Aging (NIA), National Institutes of Health (NIH), Baltimore, MD, United States

We demonstrate the clinical feasibility of high-resolution (HR) in-vivo mapping of proteoglycan water fraction (PgWF) in human knee cartilage by combining the mcDESPOT protocol for data acquisition and Bayesian Monte Carlo (BMC) analysis for data analysis. For all subjects, PgWF maps derived from low resolution datasets exhibited partial volume and magnetic susceptibility effects leading, respectively, to an overestimation and an underestimation of PgWF values in several cartilage regions. These issues were absent in HR PgWF maps. Further, BMC-mcDESPOT demonstrates high reproducibility and stability in the estimation of PgWF as compared to the conventional stochastic region contraction (SRC) algorithm.

[Effects of Fat Saturation on T2* Quantification](#)

Michael Carl¹, Amin Nazaran², Jiang Du², and Graeme M Bydder²

¹GE Healthcare, San Diego, CA, United States, ²UCSD, CA, United States

The T₂ relaxation of MRI signals is an important parameter in assessment of pathology. Here we analyze the effects that Fat Saturation pulses of various bandwidths have on the values of T₂ quantification. We found that Fat Saturation can have a notable effect on the measured T₂ values of multi-component tissues. Since the dispersion is less for smaller FS bandwidths, longer FS pulses can help to minimize the effects.

Computer 9

[UTE-MT Imaging Can Reliably Evaluate Macromolecules in MSK Tissues: A Sequential Collagenase Enzymatic Treatment Study](#)

Xin Cheng^{1,2}, Yajun Ma¹, Eric Y Chang^{1,3}, and Jiang Du¹

¹Department of Radiology, University of California San Diego, San Diego, CA, United States, ²Department of Histology & Embryology, Jinan University, Guangzhou, People's Republic of China, ³Radiology Service, VA San Diego Healthcare System, CA, United States

In this study, we aimed to evaluate UTE-MT derived macromolecule fractions in articular cartilage subject to sequential collagenase enzymatic treatment. The preliminary result suggests that UTE-MT imaging and signal modeling allows for quantitative evaluation of macromolecular fractions in articular cartilage. Furthermore, results from UTE-MT imaging and signal modeling are insensitive to the magic angle effect, which is a huge advantage over the conventional T₂ and T₁rho measures. The water and macromolecular changes in both short and long T₂ tissues in the knee joint using UTE-MT provides a "whole-organ" approach, and may be useful in the diagnosis and treatment of OA.

5094

Computer 10

[UTE-T2* Profile Analyses Correlate with Walking Mechanics 2 Years After ACL Reconstruction](#)

Ashley A Williams¹, Matthew R Titchenal¹, and Constance R Chu¹

¹Department of Orthopaedic Surgery, Stanford University, Stanford, CA, United States

This work examines the use of UTE-T₂* profile analysis to assess sub-surface knee cartilage structural changes in 26 ACL-reconstructed subjects and compares UTE-T₂* metrics to kinetic and kinematic measures of walking. UTE-T₂* profile characteristics detect differences between ACL-reconstructed and uninjured knees. Side-to-side differences in an individual's UTE-T₂* profile metrics correlate with side-to-side differences in their gait metrics. The results suggest that UTE-T₂* profile characteristics of cartilage are a useful metric for identifying cartilage subsurface changes early after ACLR and may reflect matrix changes resulting from altered loading.

5095

Computer 11

UTE-T2* Profile Analyses Correlate to Patient Reported Outcomes 2 Years After ACL Reconstruction

Ashley A Williams¹, Matthew R Titchenal¹, and Constance R Chu¹¹Department of Orthopaedic Surgery, Stanford University, Stanford, CA, United States

Identification of patients with early cartilage degeneration who are at greater risk for poor clinical outcomes is critical for development of interventions to reduce osteoarthritis risk after ACL injury. This study tested the hypothesis that UTE-T2* profile analysis of knee cartilage correlates with patient reported outcomes (PRO) in ACL-reconstructed subjects 2 years after surgery. UTE-T2* mean values and profile characteristics in 27 ACL-reconstructed subjects correlated with patient reported pain and symptoms. Side-to-side differences in UTE-T2* profiles of some high functioning individuals suggest that this UTE metric may provide earlier warning of cartilage at risk for progressive degeneration than PRO.

Computer 13

Efficacy of GelrinC in the treatment of chondral and osteochondral lesions: MRI results based on semi-quantitative MOCART scoring and T2 mapping

Markus Schreiner^{1,2}, Kitty Ohel³, Livnat Ben-Zur³, Sebastian Röhrich², Martin Zalaudek², Pavol Szomolanyi², Vladimir Juras², Vladimir Mlynarik², Reinhard Windhager¹, and Siegfried Trattnig^{2,4}¹Department of Orthopaedics, Medical University of Vienna, Vienna, Austria, ²High Field MR Center, Department of Biomedical Imaging and Image-Guided Therapy, Medical University of Vienna, Vienna, Austria, ³Regentis Biomaterials Ltd, Or Akiva, Israel, ⁴CD Laboratory for Clinical Molecular MR Imaging, Vienna, Austria

The treatment of femoral cartilage lesions still remains a challenge. Established cartilage repair techniques include microfracture (MFx), acellular scaffolds and cell based therapies such as ACI and MACI, which differ in associated morbidity and outcome. Therefore, there have been strong research efforts to develop novel treatment alternatives. In this study, we demonstrate that GelrinC, a novel acellular biodegradable implant, allows a successful treatment of both chondral and osteochondral femoral lesions in a minimal invasive one-step procedure. For both lesion types a substantial improvement of MOCART scores as well as T2 values has been demonstrated over a 24-month period.

Feasibility of GRASP DCE-MRI in children with Juvenile Idiopathic Arthritis (JIA)

Paul de Heer¹, Robert Hemke¹, Cristina Lavini¹, Jasper Schoormans², Bram F. Coolen², Anouk M. Barendregt¹, Gustav J. Strijkers², Mario Maas¹, Jaap Stoker¹, Aart J. Nederveen¹, and Jurgen H. Runge^{1,3}¹Radiology, AMC, Amsterdam, Netherlands, ²Biomedical Engineering & Physics, AMC, Amsterdam, Netherlands, ³Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom

Juvenile Idiopathic Arthritis (JIA) is the most common rheumatic disease in childhood and represents one of the leading causes of pediatric acquired disability. The aim of our study was to evaluate feasibility of high spatiotemporal resolution GRASP DCE-MRI in children with JIA and secondly to compare image quality between GRASP and conventional DCE-MRI in evaluating synovitis. In this pilot study, GRASP DCE-MRI proved to be feasible in a child with JIA. Moreover, for the evaluation of synovitis significantly higher spatial resolution and much cleaner signal-enhancement plots could be obtained using GRASP compared to conventional DCE-MRI.

Cartilage mapping in asymptomatic hips with cam-type FAI: Does the MRI T1ρ profile change over time?

Gerd Melkus^{1,2}, George Grammatopoulos³, Kawan S Rakhra^{1,2}, and Paul E Beaulé^{3,4}¹Medical Imaging, The Ottawa Hospital, Ottawa, ON, Canada, ²Radiology, University of Ottawa, Ottawa, ON, Canada, ³Orthopaedic Surgery, The Ottawa Hospital, Ottawa, ON, Canada, ⁴Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada

In this study, we investigated whether the T1ρ profile of the hip cartilage changes over time in a subject group with asymptomatic cam-type femoroacetabular impingement (FAI). After the initial T1ρ data acquisitions, the scans were repeated on the same group in a mean time interval of 3.3 years. For the majority of the subject group there were no significant T1ρ changes in the whole joint and in different hip cartilage regions. However, 1 patient (out of 12) showed significant (>20%) increased T1ρ values (i.e. proteoglycan reduction).

Computer 16

High resolution MRF-FISP with radial acquisition for MSK imaging

Dongyeob Han¹, Taehwa Hong¹, and Dong-Hyun Kim¹¹School of Electrical & Electronic Engineering, Yonsei University, Seoul, Korea, Republic of

Magnetic resonance fingerprinting (MRF) provides rapid quantification of proton density, T1 and T2 mapping using spiral acquisition. However, for high resolution imaging, spiral imaging can be limiting due to its relatively long readout time. In this study, we implemented high resolution (0.5x0.5mm²) MRF-FISP using golden angle random rotating radial acquisition.

5101

Computer 17

Texture characteristics of articular cartilage of patients with articular cartilage osteoarthritis based on MR T2 mapping images

Shan Wang¹, Cui-Ping Ren¹, Jing-Liang Cheng¹, and Zhi-zheng Zhuo²

¹The First Affiliated Hospital of Zhengzhou University, ZhengZhou, People's Republic of China, ²Clinical Science, Philips Healthcare, Beijing, People's Republic of China

We tried to evaluate OA by using the T2 mapping and the texture characteristics. Thirty-seven patients and sixteen healthy volunteers were recruited in this study. The results showed that the T2 value is higher in patients than in controls and some texture characteristics in two groups are different. It can be concluded that texture analysis combined with T2 mapping are a useful tool for diagnosis of OA patients.

5102

Computer 18

Orientation anisotropy of quantitative MRI relaxation parameters in articular cartilage

Nina Hänninen¹, Jari Rautiainen¹, Lassi Rieppo^{2,3}, Simo Saarakkala^{2,3,4}, and Mikko Johannes Nissi^{1,5}

¹Department of Applied Physics, University of Eastern Finland, Kuopio, Finland, ²Research Unit of Medical Imaging, Physics and Technology, University of Oulu, Oulu, Finland, ³Medical Research Center Oulu, Oulu University Hospital and University of Oulu, Oulu, Finland, ⁴Department of Diagnostic Radiology, Oulu University Hospital, Oulu, Finland, ⁵Diagnostic Imaging Center, Kuopio University Hospital, Kuopio, Finland

Classical and several rotating frame quantitative MR relaxation parameters have been used for evaluation of composition and structure of articular cartilage, and demonstrated to have variable sensitivity to orientation of the tissue in magnetic field. The orientation dependence of several relaxation parameters in articular cartilage have been previously investigated and were now further analyzed and compared to polarized light microscopy results. T₁, adiabatic T_{1ρ} with HS1 pulse and CW-T_{1ρ} at 2 kHz spin-lock demonstrated the least orientation dependence. Usefulness of the parameters for osteoarthritis diagnostics, as reported in the literature, was evaluated together with the orientation sensitivity.

5103

Semi-automated Segmentation of Hip Cartilage in Physiological Magnetic Resonance Imaging: A Fast, Accurate, and Clinically Viable Methodology

Daniel J Park¹, Scott Fernquest¹, Antony Palmer¹, Marija Marcan², Irina Voiculescu², and Siôn Glyn-Jones¹

¹Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, ²Department of Computer Science, University of Oxford, Oxford, United Kingdom

Physiological Magnetic Resonance imaging (pMRI) offers the potential of diagnosing osteoarthritis at a stage where patients may benefit from intervention, and acting as an assay of disease to test the efficacy of novel early intervention treatments. pMRI data, however, requires segmentation to allow morphological and biochemical quantitative analysis. Manual segmentation is time consuming and a viable automated segmentation method in the hip remains elusive. We have produced a fast, accurate, and reproducible semi-automated method of segmentation to allow wider implementation of pMRI for use in quantitative analysis of early OA in the hip in both research and clinical settings.

Comparison of T2 and T1ρ mapping of ankle cartilage between young healthy females and dancers

Hon J. Yu¹, Alex Luk¹, Jimmy Ton¹, Edward Kuoy¹, Jeff Russell², Kelli Sharp³, and Hiroshi Yoshioka¹

¹Radiological Sciences, University of California, Irvine, CA, United States, ²Science and Health in Artistic Performance, Ohio University, Athens, OH, ³Arts-Dance, University of California, Irvine, CA, United States

This study demonstrates an angular-dependent T2 and T1ρ profile of talar dome cartilage at 3T using novel angular-segmentation methodology for the potential of quantitative functional assessment of cartilage *in vivo*. The results in this study indicate T2 values over the posterior weight-bearing portion were higher in young dancers than age-matched healthy volunteers even though cartilage thickness and volumes were not significantly different between two cohorts.

5107

Computer 23

Validation study T2 and T1rho mapping of the ankle cartilage using healthy volunteers

Hon J. Yu¹, Alex Luk¹, Jimmy Ton¹, Edward Kuoy¹, Jeff Russell², Kelli Sharp³, and Hiroshi Yoshioka¹

¹Radiological Sciences, University of California, Irvine, CA, United States, ²Science and Health in Artistic Performance, Ohio University, Athens, OH, ³Arts-Dance, University of California, Irvine, CA, United States

This study demonstrates feasibility in manual segmentation of talar dome using MRI of the ankle and provides a systematic approach in assessment of image-based segmentation utilizing purely geometrical attributes and subsequent validation of angle-dependent analysis of T2 and T1 ρ mapping of the cartilage. The results clearly demonstrates the magic angle effect of the talar dome cartilage on T2 mapping and also the important fact that repeatability assessment of segmentation should be made using the geometrical attributes rather than the underlying segmentation-based quantity.

5108

Computer 24

Assessing reliability of 3D Cones UTE-T2* sequence for detecting subsurface changes in cartilage and meniscus

Aditi Guha¹, Ashley A Williams¹, and Constance R Chu¹

¹Department of Orthopedic Surgery, Stanford University, Stanford, CA, United States

The purpose of this study is to establish the reliability of the UTE-T2* mapping method using 3DCones sequence shown to detect subsurface changes in knee cartilage and meniscus. Scans were performed on cadaver knee specimen using 3DCones acquisition at 3T with 8 and 12 TEs. Reliability was assessed by the intraclass correlation coefficient (ICC) calculated as 0.77 and 0.91 for the 8 and 12 point techniques. The method is good to excellently reproducible for both techniques. Hence, the 3DCones UTE-T2* mapping technique can reliably evaluate subsurface changes in meniscus and cartilage and help identify at-risk OA patients.

Improved delineation of air-bone interface in in-vivo high-resolution bright bone ZTE MRI at 3T

Aiming Lu¹, Krzysztof R Gorny², Mai Lan Ho², John III Huston², Robert J Witte², John I Lane², Dan Rettmann³, Michael Carl³, and Gaspar Delso³

¹Mayo Clinic, Rochester, MN, United States, ²Mayo Clinical, Rochester, MN, United States, ³GE Healthcare

Using MRI for depicting solid cortical bone structures is of increasing clinical interest. Due to its low water content and short transverse relaxation time, cortical bone appears as signal void in conventional gradient echo or spin echo pulse sequences. This allows "black bone" techniques to be used when air does not confuse the visualization of cortical bone. In cases differentiation between bone tissues and air are desired "bright bone" techniques utilizing Ultrashort echo time (UTE) or Zero TE (ZTE) MRI have been proposed. Long T2-suppression methods (e.g., echo subtraction, long T2 saturation) are often applied to generate positive cortical bone contrast. However, clinical applications of these methods are still limited due to significant increase in acquisition time and reduced SNR efficiency. Recently a prototype proton density (PD)-weighted, zero TE (ZT) sequence has been demonstrated clinically. This work aims to improve the bright bone MRI using the ZTE sequence by optimizing the bone signal during data acquisition, minimizing partial volume effect with ultra high resolution data acquisition and optimizing the image processing for better bone/air differentiation.

5110

Three-Dimensional Adiabatic Inversion Recovery Prepared Ultrashort Echo Time Cones (3D IR-UTE-Cones) Imaging of Cortical Bone in the Hip

Amin Nazaran¹, Michael Carl², Yajun Ma¹, Saeed Jerban¹, Yanchun Zhu¹, Eric Y. Chang^{1,3}, and Jiang Du¹

¹The University California, San Diego, San Diego, CA, United States, ²GE Healthcare, San Diego, CA, United States, ³Radiology Service, VA San Diego Healthcare System

Ultra short echo time (UTE) techniques have been used to image cortical bone. However, imaging cortical bone in hip has been challenging due to limited signal-to-noise ratio (SNR), robust long T2 suppression, and long scan time. UTE sequences with TEs down to 32 μ s are able to acquire signal from both short and long T2* tissue. To suppress long T2* tissue, the combination of inversion recovery (IR) and UTE imaging can be used. In this report, we applied three-dimensional adiabatic inversion recovery prepared UTE with Cones trajectories (3D IR-UTE-Cones) to suppress long T2 tissue and to directly quantify cortical bone in the hip in vivo at 3T.

- The assessment of vertebral bone marrow fat unsaturation is attracting growing interest for applications in bone metabolism and osteoporosis. Especially in younger subjects, the presence of a strong and broad water peak confounds the extraction of surrounding peaks (olefinic and glycerol peaks), which are used for the determination of fat unsaturation. Inversion-recovery spectroscopy allows the extraction of these peaks by differentiating the signals based on different T1 relaxation times between water and fat. The feasibility of using inversion-recovery spectroscopy was evaluated in a phantom experiment in comparison with gas chromatography and in vivo in four young and healthy volunteers.

Bone Imaging Using MR: Inversion Recovery Vs Tissue Segmentation

Michael Carl¹, Graeme McKinnon², and Gaspar Delso³¹GE Healthcare, San Diego, CA, United States, ²GE Healthcare, WI, United States, ³GE Healthcare, United Kingdom

Many musculoskeletal tissues such as cortical bone have very short transverse relaxation times and require specialized pulse sequences such as UTE or ZTE for optimal signal acquisition. Recently, these sequences have been used to directly visualize cortical bone by suppressing surrounding long T2 tissues such as fat or muscle by either magnetization preparation using inversion recovery, or logarithmic tissue segmentation. In this work, we compare these techniques on a cadaveric bovine knee specimen. Both inversion recovery UTE as well as tissue segmented ZTE imaging proved promising method for direct bone imaging with CT-like image appearance.

Accuracy of Age Estimation based on Undersampled MR Images of the Hand

Bernhard Neumayer^{1,2}, Matthias Schloegl³, Christian Payer⁴, Thomas Widek^{1,2}, Thomas Ehammer¹, Rudolf Stollberger^{2,3}, and Martin Urschler^{1,2,4}¹Ludwig Boltzmann Institute for Clinical Forensic Imaging, Graz, Austria, ²BioTechMed-Graz, Graz, Austria, ³Institute of Medical Engineering, Graz University of Technology, Graz, Austria, ⁴Institute for Computer Graphics and Vision, Graz University of Technology, Graz, Austria

The topic of age estimation in living persons is important for sports competitions as well as unaccompanied minors without valid documents and has recently gained interest. Recommended imaging protocols are based on modalities using ionizing radiation and therefore MRI is currently investigated for its eligibility to replace these measurements. This study investigates the accuracy of MRI-based age estimation for retrospectively undersampled data to determine the degree of inaccuracies introduced by an acceleration of the acquisition technique using commercially available undersampling strategies. For this purpose the data is analyzed by a radiologist and using an automatic method.

MRE derived stiffness of the gluteus maximus muscle: reproducibility and correlation to T2 and fat-fraction

Jules L. Nelissen^{1,2}, Dorien Verschuren¹, Larry de Graaf¹, Cees W. J. Oomens³, Klaas Nicolay¹, Ralph Sinkus⁴, Jurgen H. Runge^{4,5}, Aart J. Nederveen⁵, and Gustav J. Strijkers²¹Biomedical NMR, Eindhoven University of Technology, Eindhoven, Netherlands, ²Preclinical and Translational MRI, Academic Medical Center, Amsterdam, Netherlands, ³Biomechanics of Soft Tissues, Eindhoven University of Technology, Eindhoven, Netherlands, ⁴Division of Imaging Sciences & Biomedical Engineering, King's College London, London, United Kingdom, ⁵Radiology, Academic Medical Center, Amsterdam, Netherlands

Skeletal muscle pathology is often accompanied by abnormal fat deposition, fibrosis, and edema. Altered muscle biomechanical properties associated with these compositional changes can be quantitatively assessed with MRE. We present MRE measurements of the gluteus maximus muscle. In healthy volunteers, we have tested reproducibility and correlated the shear modulus G_d to T_2 and fat-fraction FF_{dx} measured using Dixon. Acceptable intra and inter reproducibility was found. Expected difference in G_d between gluteus maximus and subcutaneous fat was confirmed. Correlation plots of T_2 and FF_{dx} with G_d showed that MRE can derive biomechanical properties that potentially can provide additional information to characterize skeletal muscle pathology.

Mapping of Intramyocellular Lipid Content in Foot Muscle

Kenneth Wengler^{1,2}, Chien-Hung Lin², Mingqian Huang², Elaine Gould², Mark Schweitzer², and Xiang He²¹Biomedical Engineering, Stony Brook University, Stony Brook, NY, United States, ²Radiology, Stony Brook University, Stony Brook, NY, United States

Diabetic neuropathy is a leading cause of diabetic foot ulcer and has been shown to be induced by insulin resistance. Intramyocellular lipid (IMCL) measured by MRS in large skeletal muscles has been shown to correlate with insulin resistance. In this study a generalized Lorentzian approximation is used to estimate the IMCL and EMCL frequency shift as a function of muscle fiber bundle orientation. DTI is used to measure the fiber bundle orientation and provide prior information for IMCL/EMCL peak fitting. 2D-CSI is used to quantify IMCL contents in foot muscle groups of healthy subjects and diabetic patients.

Age-related changes in healthy thigh musculature: Multi-parametric MR imaging analysis

Min A Yoon¹, Suk-Joo Hong¹, Chang Ho Kang², Kyung-Sik Ahn², Baek Hyun Kim³, and In Seong Kim⁴

¹Department of Radiology, Korea University Guro Hospital, Seoul, Korea, Republic of, ²Department of Radiology, Korea University Anam Hospital, Seoul, Korea, Republic of, ³Korea University Ansan Hospital, Gyeonggi-do, Korea, Republic of, ⁴Siemens Healthcare Korea, Seoul, Korea, Republic of

Purpose: To identify MR parameters that are significantly associated with aging in healthy thigh muscles and investigate age-related characteristics.

Methods: Thirty healthy subjects underwent multi-parametric MRI of the right thigh, including IVIM-DWI, DTI, multi-echo Dixon imaging, DCE-MRI. Parametric maps of the thigh muscles (divided into three compartments) were analyzed. Relationships between parameters and age were assessed with simple and multiple linear regression analyses.

Results: Fractional anisotropy (slope=1.018) and V_e (slope=2.151) in anterior compartment and fat percentage in posterior compartment (slope=2.031) showed significant relationships to age (p<0.05).

Conclusion: Several MRI parameters of the thigh muscles were associated with normal aging.

Quantitative Lower Limb Perfusion Territory Imaging with Vessel Encoded Arterial Spin Labeling

Lian Ding¹, Fei Gao², Chengyan Wang¹, Wenjian Huang¹, Jue Zhang^{1,2}, Xiaoying Wang^{1,3}, and Jing Fang^{1,2}

¹Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, People's Republic of China, ²College of Engineering, Peking University, Beijing, People's Republic of China, ³Department of Radiology, Peking University First Hospital, Beijing, People's Republic of China

Critical limb ischemia (CLI) represents the most severe clinical manifestation of peripheral arterial disease (PAD). It has been proved that lower extremity arterial stenosis and collateral circulation compensatory ability after occlusion play an important role on CLI. This study proposed a strategy for assessment of lower extremity arterial stenosis and collateral circulation compensatory ability by the noninvasive vessel-encoded arterial spin labeling (VEASL) to quantitatively assess perfusion territory of lower extremity arterial. The lower limb perfusion territory image and the angiosome map were obtained in this study, indicating the potential of VEASL for CLI assessment.

Evaluation of T1p time in the quadriceps muscle after an Anterior Cruciate Ligament Reconstruction: Relationship to muscle strength and injury recovery

Brian Noehren^{1,2}, Richard Lawless³, Peter Hardy⁴, Anders Andersen³, and Moriel Vandsburger^{5,6}

¹Rehabilitation Sciences, University of Kentucky, Lexington, KY, United States, ²Orthopaedic Surgery, University of Kentucky, Lexington, KY, United States, ³University of Kentucky, Lexington, KY, United States, ⁴Radiology, University of Kentucky, Lexington, KY, United States, ⁵Department of Physiology, University of Kentucky, Lexington, KY, United States, ⁶Department of Bioengineering, University of California Berkeley, CA, United States

Anterior Cruciate Ligament Injuries are associated with long term loss of quadriceps muscle strength. Accumulation of greater collagen in the extracellular matrix around muscle fibers could limit recovery. T1p applied to the quadriceps muscle could identify patients at risk for not having a good recovery because of collagen deposition. T1p imaging of the injured and non injured quadriceps of 6 subjects was performed. We found significantly higher T1p times in the injured limb as well as a significant association to greater muscle weakness. These results show the potential application of T1p to identify individuals with muscle dysfunction.

Computer 20

Evaluation of fast radial T1 mapping for skeletal muscle tissue characterization

Benjamin Marty^{1,2}, Bertrand Coppa^{1,2}, Pierre-Yves Baudin³, and Pierre G. Carlier^{1,2}

¹NMR Laboratory, Institute of Myology, Paris, France, ²NMR Laboratory, CEA, DRF, I²BM, MIRCen, Paris, France, ³Consultants for Research in Imaging and Spectroscopy, Tournai, Belgium

The development of quantitative NMR outcome measures in order to monitor natural history of neuromuscular disorders or therapeutic interventions is crucial. Global muscle T1 values is strongly affected in chronic disease when healthy muscle is replaced by fat and this parameter can be used for diagnostic purposes. Nevertheless, very little is known about the effects of tissue water compartmentation and distribution on muscle T1 values. Here, we investigated the variations of skeletal muscle T1 values under various physiological conditions using a fast T1 mapping sequence and evaluated the potential of this biomarker in the context of disease monitoring.

5129

Computer 21

Quantitative evaluation of supraspinatus fatty infiltration and its relationship with tendon tear severity by using mDIXON-Quant technique
Jin Qu¹, Xinwei Lei¹, Ying Zhan¹, Huixia Li¹, Yingying An¹, and Zhizheng Zhuo²

¹Tianjin First Center Hospital, Tianjin, People's Republic of China, ²Philips Healthcare, Beijing, People's Republic of China

The purpose of this study was to evaluate fatty infiltration of supraspinatus quantitatively using fat fraction measurements and investigate the relationship between fatty infiltration, muscle atrophy and tendon tear severity. Quantitative assessment of fatty infiltration was performed using 3T MRI with a mDIXON-Quant technique in 85 patients. The degree of fatty infiltration and muscle atrophy significantly increase with the extent of rotator cuff tear. The tendon tear severity correlated with fatty infiltration and muscle atrophy, and muscle atrophy correlated with fatty infiltration. mDIXON-Quant can be a reliable and accurate tool to quantify fatty degeneration of the rotator cuff muscles.

Phosphodiester-levels in Muscle Assessed using 31P MRS are an Early Marker for Disease Activity in DMD

Melissa T. Hooijmans¹, Nathalie Doorenweerd^{1,2}, Jędrzej Burakiewicz¹, Celine A. Baligand¹, Jan J.G.M. Verschuuren², Andrew G. Webb¹, Erik H. Niks², and Hermien E. Kan¹

¹C.J.Gorter Center for High-field MRI, Dept. of Radiology, Leiden University Medical Center, Leiden, Netherlands, ²Dept. of Neurology, Leiden University Medical Center, Leiden, Netherlands

Quantitative MR of muscle is increasingly important as potential outcome measure for therapy development in DMD. Since therapy is aimed at preserving or improving muscle tissue, an early marker that reflects muscle state with a suitable dynamic range is essential. Unfortunately, water T2 and %fat do not meet this criteria. Therefore, we aimed to assess whether phosphodiester (PDE)-levels detected by 31P MRS could fill this gap. We have shown a two-fold increase in PDE-levels compared to controls and its detection prior to structural changes which confirm the potential of PDE as an early marker for disease activity in DMD patients.

Measurement and Correction for the Magnetic Susceptibility Effects of Fat in Venous Oximetry: Application in the Quantification of Muscle Oxygen Consumption (VO₂) with Plantar Flexion Exercise

Esther H Yang¹, Amy A Kirkham¹, and Richard B. Thompson¹

¹Biomedical Engineering, University of Alberta, Edmonton, AB, Canada

The magnetic field shift within cylindrical blood vessels can be used to estimate venous oxygen saturation, based on the magnetic susceptibility of deoxyhemoglobin. However, conduit veins in the periphery are often surrounded by fat, which has a larger magnetic susceptibility than water and the venous blood pool. It is shown that the magnetic susceptibility effects of fat can confound estimation of venous oxygen saturation. A new method to correct for these effects is described with application for plantar flexion exercise, for the measurement of muscle oxygen extraction, blood flow and calculation of oxygen consumption (VO₂).

Correlation Between Bone Marrow Fatty Deposition Under Vertebral Endplates with Lumbar Intervertebral Disc Degeneration

Xiaodong Zhang¹, Yinxia Zhao¹, Yingjie Mei², and Shaoyong Hu¹

¹Department of medical radiology, The Third Affiliated Hospital of Southern Medical University (Academy of orthopedics •Guangdong Province), Guangzhou, People's Republic of China, ²Philips Healthcare, Guangzhou, People's Republic of China

The intervertebral disc without blood supply obtained nutrient substance diffusing from the microcirculation under vertebral endplates. Some studies showed the fat deposition of bone marrow may pressure vessels and blood sinus, which could affect the microcirculation. So the fatty content of bone marrow under vertebral endplates can reflect the degeneration of the vertebral. However, the correlation of fatty content of bone marrow with lumbar intervertebral disc degeneration is not clear. The purpose of our study was to analyze the correlation between bone marrow fatty fraction under vertebral endplates with Pfirrmann Grades and T2* value of lumbar intervertebral disc.

Dynamic Morphometric Changes in Degenerative Lumbar Spondylolisthesis: A Pilot Study of Standing Magnetic Resonance Imaging
Raphaële charest-morin¹, Honglin Zhang², Michael Bond³, Amy Phillips⁴, Shannon Patterson⁵, David Wilson³, and John Street³

¹Department of Orthopaedics, Centre Hospitalier Universitaire de Québec, Québec, QC, Canada, ²Department of Orthopaedics, University of British Columbia, Vancouver, BC, Canada, ³Department of Orthopaedics, University of British Columbia, ⁴Center for Hip Health and Mobility, University of British Columbia, ⁵Department of Radiology, Vancouver General Hospital

The planning of spine surgery for degenerative lumbar spondylolisthesis (DLS) is currently based on supine MR images while patients experience symptoms in the upright posture. This study employed an upright Open MRI to determine whether the MRI-based measurements of the spinal and neural elements used in planning surgery are different in the symptomatic, upright posture than in the supine posture. We found upright MRI scanning detected dynamic morphometric differences in a number of clinically important radiographic parameters in patients with DLS. Upright MRI may help in planning minimally invasive surgeries for DLS.

Changes in tracer kinetics in the endplates of degenerating intervertebral discs

L. Tugan Muftuler¹, Volkan Emre Arpinar², and Ali Ersoz³

¹Department of Neurosurgery, Medical College of Wisconsin, Milwaukee, WI, United States, ²Department of Radiology, Medical College of Wisconsin, Milwaukee, WI, United States, ³Department of Biophysics, Medical College of Wisconsin, Milwaukee, WI, United States

This study investigated changes in perfusion and diffusion in the cartilaginous endplates and subchondral bones around the degenerating discs. It has been suggested that such abnormalities might indicate inflammatory changes that might lead to chronic low back pain. A high spatial and temporal resolution DCE-MRI technique was implemented and tested on a group of volunteers. Pharmacokinetic model was used to quantify the changes in the regions of interest. Results demonstrated significant changes in contrast agent uptake and washout in the cartilaginous and bony endplate regions as the adjacent disc degenerated.

Whole body FDG PET/MRI for assessment of facet joint osteoarthritis: Direct comparison of FDG uptake with MRI and CT features

Munenobu Nogami^{1,2}, Shinsuke Shimoyama², Yuichi Wakabayashi², Utaru Tanaka², Yoshiaki Watanabe³, Akihito Ohnishi², Tatsuya Nishij², Yoshiko Ueno², Atsushi K Kono³, Kazuhiro Kubo², Satoru Takahashi², and Kazuro Sugimura²

¹Department of Radiology, Hyogo Cancer Center, Akashi, Japan, ²Department of Radiology, Kobe University Graduate School of Medicine, Kobe, Japan, ³Department of Radiology, National Cerebral and Cardiovascular Center, Suita, Japan

Hybrid PET/MRI scanner is an emerging modality and utilized not only for oncological or neurological purposes but also for assessment of musculoskeletal disease. Simultaneous acquisition of PET and MRI enables precise anatomical localization of PET tracers and further understanding of mechanism of the tracer uptake by using MRI information. Our hypothesis was that PET/MRI can reveal the pathophysiological mechanism of facet joint osteoarthritis by the simultaneous whole body imaging. The results showed MRI features on PET/MR significantly correlated with FDG uptake in the facet joint osteoarthritis and may be superior to CT based evaluation.

5137

Computer 29

Vertebral strength prediction in diabetic patients: quantification of bone marrow fat content obtained by IDEAL-IQ

Shinpei Yamaguchi¹, Takatoshi Aoki¹, Koichi Nakagami¹, Masami Fujii¹, Yoshiko Hayashida¹, Yosuke Okada², Yoshiya Tanaka², and Yukunori Korogi¹

¹Radiology, University of Occupational and Environmental Health, Kitakyushu, Japan, ²First department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan

Although bone mineral density (BMD) by dual X-ray absorptiometry (DXA) has been used to predict bone strength, diabetes mellitus (DM) patients have an elevated fracture risk despite normal BMD. We evaluated the availability of the fat fraction (FF) using IDEAL-IQ for vertebral strength prediction in DM patients. The correlation between the failure load by CT-based finite-element method and the BMD with age and the FF using IDEAL-IQ was significantly higher than that between the failure load and the BMD alone ($p < .001$). FF using IDEAL-IQ in combination with BMD measurements can potentially be used in predicting bone strength in DM patients.

5138

Computer 30

3D variable flip angle fast spin echo imaging of the cervical spine : Improved image quality and decreased scan time with outer volume suppression

Ho-Joon Lee¹, Suchandrima Banerjee², Dong Eun Kim³, Sung-Min Cho³, and Seung-Koo Lee¹

¹Radiology, Yonsei University College of Medicine, Seoul, Korea, Republic of, ²Global MR Applications & Workflow, GE Healthcare, Menlo Park, CA, ³GE Healthcare, Seoul, Korea, Republic of

Application of the volumetric fast spin echo (FSE) imaging in MRI is increasing, due to innate capability for multi-planar reconstruction, and potentials for a simplified workflow. However application to the cervical and thoracic area may be challenging because ghosting/phase encoded motion artifacts from swallowing, respiration and pulsations are frequent and severe in these regions, leading to image degradation. 3D FSE with outer volume suppression is a robust method for imaging the cervical spine, which provides improved image quality at a decreased scan time.

5139

Computer 31

Preliminary investigation: Gaussian and non-Gaussian measurements of water diffusion in diagnostic differentiation of focal lesions of malignant spinal bone tumors

Miyuki Takasu¹, Yuji Akiyama¹, Kazushi Yokomachi¹, Yoko Kaichi¹, Chihiro Tani¹, Koichi Oshio², and Kazuo Awai¹¹Diagnostic Radiology, Hiroshima University Hospital, Hiroshima, Japan, ²Diagnostic Radiology, Keio University School of Medicine, Japan

We compared the potential of various diffusion parameters obtained from Gaussian and non-Gaussian diffusion models in differentiating focal lesions of malignant spinal tumors. Mean signal intensity was calculated by placing ROIs within focal lesions for 9 b-values in each subject. ADC, frac<1, frac>3, and PG(D) differed significantly between focal lesions of myeloma and LCA. Frac>3 and PG(D) was significantly different between focal lesions of myeloma and MMK. Non-Gaussian diffusion parameters may provide additional information and improve the differentiation of malignant focal lesions compared with conventional diffusion parameters, which would be helpful in improving therapy strategies.

5140

Computer 32

Q-space imaging is a novel technique to evaluate intervertebral disc degeneration.

Daisuke Nakashima¹, Nobuyuki Fujita¹, Junichi Hata^{2,3}, Takeo Nagura¹, Kanehiro Fujiyoshi⁴, Hideyuki Okano^{2,3}, Masahiro Jinzaki⁵, Morio Matsumoto¹, and Masaya Nakamura¹¹Department of Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan, ²Department of Physiology, Keio University School of Medicine, Tokyo, Japan, ³Central Institute for Experimental Animals, Kawasaki, Japan, ⁴Department of Orthopaedic Surgery, Murayama Medical Center, Japan, ⁵Department of Radiology, Keio University School of Medicine, Tokyo, Japan

Pfirsman classification on T2WI has been the qualitative grading of intervertebral disc (IVD) degeneration which is difficult to classify subtle changes of degeneration. A quantitative and more sensitive classification system has been sought.

In this research, probability at zero displacement obtained from Q-space imaging (QSI) which is a quantitative diffusion-weighted MRI procedure made it possible to observe the effect of the regenerative antioxidant drug: N-Acetyl Cysteine on IVD degeneration which could not be observed by using T2 mapping.

Probability at zero displacement obtained from QSI has the possibility to be a novel biomarker of IVD degeneration.

5141

Computer 33

T1rho Imaging Quantification of Early Intervertebral Disc Degeneration in Pilots on 3.0T Magnetic Resonance

Xiulan Zhang¹, Yongmin Bi², Wanshi Zhang², and Lizhi Xie³¹Radiology Department, The First People's Hospital of Jingzhou, Jingzhou, China, People's Republic of, Jingzhou, People's Republic of China, ²Department of CT&MRI, Air Force General Hospital, Beijing, China, People's Republic of, ³GE Healthcare, MR Research China, Beijing, China, People's Republic of

Degenerative disc disease is an occupational disease of the military pilots, which seriously influences their health and normal training. Early disc degeneration begins with changes in biochemical compositions which is mainly characterized by proteoglycan loss and cannot be detected on conventional MRI imaging^[1-2]. T1rho is a quantitative imaging technique to reflect changes in the extracellular matrix, such as modifications in the intervertebral disc PG content^[3]. In this study, Bivariate correlation analysis was performed to compare T1rho values to the degenerative grade, disc space level, age and flight time of the pilots. T1rho values of Lumbar intervertebral discs in pilots demonstrated significantly negative correlations with degenerative grade, age and flight time, except for disc space levels. T1rho can be potentially used as a valid clinical method in the quantitative diagnosis of early intervertebral disc degeneration in asymptomatic Pilots.

5142

Computer 34

The comparison of full FOV and reduced-FOV IVIM Diffusion-weighted imaging of Spinal bone marrow

Dong Xing¹, Yunfei Zha¹, Fang Liu¹, Liang Li¹, Feifei Zeng¹, Yuan Lin¹, Wei Gong¹, Lei Hu¹, Jiao Wang¹, Bing Wu², and Hui Lin²¹Department of Radiology, Renmin Hospital of Wuhan University, Wuhan, People's Republic of China, ²GE healthcare China

IVIM (Intravoxel incoherent motion) provides perfusion quantification without the need for intravenous contrast injection, and has been used to the spinal bone marrow lesions^{1,2}. However, diffusion weighted imaging is prone to image deformation, especially with a large FOV. Hence the quantitative measurement of IVIM in spinal bone marrow may be affected. Reduced FOV DWI is known to reduce the level of image distortion, and the purpose of this study is to compare the IVIM parameters obtained using full FOV or reduced FOV imaging.

5143

Computer 35

Improved visualization of diffusion-prepared MR neurography (SHINKEI) in the pelvis using high-intensity reduction (HIRE) technique

Hitoshi Tadenuma¹, Kayoko Abe², Masami Yoneyama³, Yasuhiro Goto¹, Makoto Suzuki¹, Mamoru Takeyama¹, and Shuji Sakai²¹Department of Radiological Service, Tokyo Women's Medical University, Tokyo, Japan, ²Department of Diagnostic Imaging and Nuclear Medicine, Tokyo Women's Medical University, Tokyo, Japan, ³Philips Electronics Japan, Ltd, Tokyo, Japan

The role of MRI in the diagnosis of Lumbrosacral plexopathy is in depiction of the anatomical detail of pelvic nerves. This study attempted the improvement of the pelvic nervous depiction using HIRE-SHINKEI. This applies HIRE technique, and requires both SHINKEI and additional 3D heavily T2W scan to subtract the data. HIRE-SHINKEI can improve the depiction of nerves by subtracting signals of the background. This new technique has great potential to help the diagnosis for the peripheral nerve disorders of the lumbosacral region.

5144

Computer 36

Differential Diagnosis of Myeloma, Lymphoma, and Metastatic Cancer in the Spine Using DCE-MRI Kinetic Parameters

Ning Lang¹, Huishu Yuan¹, and Min-Ying Su²¹Department of Radiology, Peking University Third Hospital, Beijing, People's Republic of China, ²Tu and Yuen Center for Functional Onco-Imaging, Department of Radiological Sciences, University of California, Irvine, CA, United States

A retrospective DCE-MRI of 23 patients with confirmed myeloma and 13 patients with spinal lymphoma were found. A group of 76 patients with different metastatic cancers in the spine was used as a comparison group. Three heuristic parameters: the steepest wash-in enhancement ratio, the initial area under the curve (IUAC) enhancement ratio, and the wash-out slope were measured. In the ROC analysis based on the wash-out slope, myeloma can be differentiated from lymphoma with AUC=0.913, and from mets with AUC=0.828. The wash-out slope can also differentiate lung mets from breast mets with AUC=0.812, and from thyroid mets with AUC=0.891.

Radiomics of Musculoskeletal Masses Using T2-Weighted Magnetic Resonance Images

Stephen M Fisher¹, Alfonso Rodriguez², Jing Wang², Michael Folkert², and Avneesh Chhabra¹

¹Radiology, UT Southwestern, Dallas, TX, United States, ²Radiation Oncology, UT Southwestern, Dallas, TX, United States

Texture analysis has yet to be exploited in musculoskeletal tumors. In this study we aimed to create a novel predictive model based on features of benign and malignant musculoskeletal masses and test this model against existing methods used in other parts of the body. Our workflow shows promise for creating accurate classifiers of benign and aggressive tumors based on T2-weighted MRI images.

5146

Computer 38

Comparison of whole-body morphologic and functional MRI with automated "bone subtraction" CT-image analysis for monitoring of longitudinal spine involvement in patients with multiple myeloma

Marius Stefan Horger¹, Sebastian Werner¹, Wolfgang Thaiss², and Christopher Kloth¹

¹Radiology, Eberhard-Karls-University Tuebingen, Tuebingen, Germany, ²Radiology, Eberhard-Karls-University Tuebingen, Tuebingen, Germany

Imaging diagnosis and therapy monitoring of multiple myeloma (MM) is challenging due to the combined bone and bone marrow involvement and at the same time often imperative due to possible failure of hematological markers (e.g. non-secretory myeloma). MRI is the most powerful MM-imaging technique for visualization of medullar involvement whereas CT optimally detects myeloma bone-disease (BMD). A new CT post-processing software (bone subtraction-BS) is generating subtraction (difference) maps of baseline and follow-up non-enhanced CT exams highlighting the course of BMD. Hence, the purpose of this study was to assess strengths and limitations of these two imaging modalities for longitudinal disease monitoring.

5147

Dynamic susceptibility contrast perfusion MR imaging in distinguishing malignant from benign soft tissue tumors in limbs: A pilot study

Yitong Bian¹, Guohong Jin², Yanliang Wang³, Gang Niu¹, and Jian Yang¹

¹First Affiliated Hospital of Xi'an Jiaotong University, Xian, People's Republic of China, ²General Affiliated Hospital of Ningxia Medical University, Yinchuan, People's Republic of China, ³Luoyang Central Hospital Affiliated to Zhengzhou University

Precise differential and qualitative diagnoses for extremities soft tissue tumors (STTs) are of vital importance. Dynamic susceptibility contrast perfusion MRI (DSC-MRI) enables assessment of overall tumor vascularity, allowing indirect evaluation of the biological aggressiveness of tumors. Therefore, this study aims to discuss the feasibility of DSC-MRI to preliminarily assess in the differentiation between benign and malignant extremities STTs. Our results showed that DSC-MRI might be a non-invasive imaging technique that can play a role in identifying malignant and benign STTs in limbs and provide reliably pathological or physiological information for clinic.

5148

Computer 40

Texture analysis based on intra-voxel incoherent motion MR imaging for the differentiation of benign and malignant bone tumors

Ying Li¹, Cuiping Ren¹, Jingliang Cheng¹, and Zhizheng Zhuo²

¹Zhengzhou University First Affiliated Hospital, Zhengzhou, Henan, People's Republic of China, ²Clinical Science, Philips Healthcare, People's Republic of China

This work investigated and evaluated the role of texture analysis based on intra-voxel incoherent motion (IVIM) MR imaging to characterize the bone tumors, and furtherly evaluate the ability of the texture parameters to differentiate benign and malignant bone tumors by using a couple of classifiers, which might be helpful for clinical diagnosis and studies. The texture parameters have the ability to characterize the bone tumor and the naïvebayes classifier showed the best performance in the differentiation of benign and malignant bone tumors.

5149

Dynamic Contrast-Enhanced Magnetic Resonance Imaging Parameters in Metastatic Bone Lesions of Non-small Cell Lung Cancer: Comparison between Lesions with and without Epidermal Growth Factor Receptor (EGFR) Mutation in Primary Cancer

Hyun Su Kim¹ and Young Cheol Yoon¹

¹Radiology, Samsung medical center, Seoul, Korea, Republic of

The presence of the epidermal growth factor receptor (EGFR) gene mutation is associated with a high rate of distant metastasis and poor prognosis in patients with non-small cell lung cancer (NSCLC). EGFR signaling acts as mediator of bone metastasis by increasing tumor cell proliferation and promotes synthesis and secretion of numerous angiogenic growth factors. We propose that metastatic bone lesions with and without the EGFR mutation in primary NSCLC have different perfusion profiles and dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) parameters can reveal the differences.

5153

Computer 45

Meniscus T2 Relaxation Time in Patients with Varying Degrees of Knee Joint Degeneration

Richard Kijowski¹, Benjamin Beduhn¹, Michael G Fazio¹, and Fang Liu¹

¹Department of Radiology, University of Wisconsin-Madison, Madison, WI, United States

This study was performed to investigate changes in meniscus T2 relaxation time at various stages of knee joint degeneration. T2 mapping was performed on the knees of 121 patients with meniscus tears. T2 of the torn and unorn portions of the medial and lateral meniscus were measured. The severity of radiographic osteoarthritis was assessed using the Kellgren-Lawrence (KL) grading scale. There was a significant difference ($p < 0.001$) in meniscus T2 between KL0, KL1, and KL2 subjects in both the torn and unorn portions of the meniscus with KL2 subjects having the highest T2 and KL0 subjects having the lowest T2.

Circumferential and Radial Variations in T2, T2* and T1rho in the Osteoarthritic Meniscus

Marianne Susan Black¹, Garry Evan Gold², Marc Elliot Levenston¹, and Brian Andrew Hargreaves²

¹Mechanical Engineering, Stanford University, Stanford, CA, United States, ²Radiology, Stanford University, Palo Alto, CA, United States

The menisci of the knee are important for distributing load at the knee joint, and meniscal damage has been shown to precede cartilage degeneration in the knee. We examined radial and circumferential meniscal variation in T2, T2* and T1rho relaxation times in osteoarthritic menisci. Menisci were divided into 3 circumferential regions (anterior, body, and posterior) and then further into 3 radial regions (inner, middle, and outer). Significant differences were found between circumferential and radial regions for T2, but only between circumferential regions for T2* and T1rho. Changes in meniscal regional variations could be important in tracking osteoarthritis disease progress.

Computer 47

T2-Mapping Relaxation Time Correlates with Histopathological Degree of Degeneration in Meniscal Tissue

Susanne Eijgenraam¹, Frans Bovendeert¹, Yvonne Bastiaansen², Duncan Meuffels², Jamal Guenoun¹, Stefan Klein³, Max Reijman², and Edwin Oei¹

¹Radiology and Nuclear Medicine, Erasmus MC, Rotterdam, Netherlands, ²Orthopedic Surgery, Erasmus MC, Rotterdam, Netherlands, ³Medical Informatics, Erasmus MC, Rotterdam, Netherlands

To validate meniscal T2-mapping, which is suggested to detect early meniscal degeneration, T2 relaxation times of ten menisci (five traumatically torn and five degenerative menisci from 10 patients) were compared to histopathology as the gold standard to assess meniscal degeneration. T2 relaxation times were found to correlate well with histopathological degree of degeneration in meniscal tissue ($r_s = 0.64$, $P = 0.001$). Degenerative meniscal tissue was found to exhibit significantly higher T2 relaxation times compared to non-degenerated meniscal tissue (22.7 ± 3.0 ms and 18.2 ± 5.1 ms ($P = 0.02$) respectively). Therefore, T2-mapping is a promising quantitative imaging biomarker for meniscal degeneration.

Computer 49 [Parallel Imaging Reconstruction from Randomly Undersampled Data with k-space Variant Sparsity Constraints](#)
Yu Y. Li^{1,2}

¹Cardiac Diagnostic Imaging, St. Francis Hospital, Roslyn, NY, United States, ²Radiology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States

A new parallel imaging reconstruction framework is proposed to accelerate MRI using both coil sensitivity and data sparsity. This framework uses random undersampling and performs parallel imaging reconstruction with a k-space variant constraint. No calibration data are needed. It is demonstrated that this new approach offers a gain over conventional parallel imaging in imaging acceleration.

5157

Computer 50 [Iterative SENSE with Integrated EPI Nyquist Ghost and Distortion Corrections](#)
Uten Yarach^{1,2}, Hendrik Mattern¹, and Oliver Speck¹

¹Department of Biomedical Magnetic Resonance, Otto-von-Guericke University Magdeburg, Magdeburg, Germany, ²Department of Radiological Technology, Chiang Mai University, Chaigmai, Thailand

The quality of EPI image is intrinsically hindered by Nyquist ghost and geometric distortion which are commonly handled by a 1D non-phase encoded reference and a field map based corrections, respectively. In some cases, a 2D phase reference is required, but scan time is increased. The geometric-mismatch between EPI and coil sensitivities is another concern. Here, the 2D phase correction (without prolonging scan time) and the distortion correction are integrated into a single forward operator rather than considering them consecutively. The results show that the stable reduction in Nyquist ghosting and distortion can improve the tSNR of EPI time series.

5158

Computer 51 [Fast 3D Variable-FOV Reconstruction for Parallel Imaging with Localized Sensitivities](#)
Yigit Baran Can¹, Efe Ilıcak^{1,2}, and Tolga Çukur^{1,2,3}

¹Electrical and Electronics Engineering, Bilkent University, Ankara, Turkey, ²National Magnetic Resonance Research Center (UMRAM), Bilkent University, Ankara, Turkey, ³Neuroscience Program, Bilkent University, Ankara, Turkey

Several successful iterative approaches have recently been proposed for parallel-imaging reconstructions of variable-density (VD) acquisitions, but they often induce substantial computational burden for non-Cartesian data. Here we propose a generalized variable-FOV PILS reconstruction 3D VD Cartesian and non-Cartesian data. The proposed method separates k-space into non-intersecting annuli based on sampling density, and sets the 3D reconstruction FOV for each annulus based on the respective sampling density. The variable-FOV method is compared against conventional gridding, PILS, and ESPIRiT reconstructions. Results indicate that the proposed method yields better artifact suppression compared to gridding and PILS, and improves noise conditioning relative to ESPIRiT, enabling fast and high-quality reconstructions of 3D datasets.

Computer 52 [Analytical G-factor Calculation for Slice-GRAPPA with Dual "Even-Odd" Kernels \(SG-DK\)](#)

Haifeng Wang^{1,2}, Jonathan R. Polimeni^{1,2,3}, Berkin Bilgic^{1,2}, Lawrence L. Wald^{1,2,3}, and Kawin Setsompop^{1,2}

¹Massachusetts General Hospital, Boston, MA, United States, ²Harvard Medical School, Boston, MA, United States, ³Harvard-MIT Division of Health Sciences and Technology, Massachusetts Institute of Technology, Cambridge, MA, United States

Slice-GRAPPA (SG) is often used to reconstruct blipped-CAIPI simultaneous multi-slice EPI data, in particular in conjunction with the dual even-odd kernel approach (SG-DK) to mitigate ghosting related reconstruction artifacts. To achieve good performance in blipped-CAIPI acquisition, the CAIPI shift factor should be optimized in a case by case manner to minimize g-factor penalty. The g-factor is influenced by the reconstruction approach and so far a fast analytical g-factor calculation has been developed only for standard SG reconstruction but not SG-DK, where time-consuming Monte Carlo simulation is still needed. Here we propose an analytical g-factor calculation for SG-DK and demonstrate that the proposed method is fast and accurate. Our simulation and experimental results also highlight the superior performance of SG-DK over SG reconstruction, both in mitigating image artifacts and noise penalty.

5160

Computer 53 [ENLIVE: A Non-Linear Calibrationless Method for Parallel Imaging using a Low-Rank Constraint](#)

H. Christian M. Holme^{1,2}, Frank Ong³, Sebastian Rosenzweig^{1,2}, Robin N. Wilke^{1,2}, Michael Lustig³, and Martin Uecker^{1,2}

¹Diagnostic and Interventional Radiology, University Medical Center Göttingen, Göttingen, Germany, ²partner site Göttingen, DZHK (German Center for Cardiovascular Research), Göttingen, Germany, ³Electrical Engineering and Computer Sciences, University of California, Berkeley, Berkeley, CA, United States

We propose an extension to Regularized Non-Linear Inversion (NLINV), which simultaneously reconstructs multiple images and sets of coil sensitivity profiles. This method, termed ENLIVE (Extended Non-Linear InVersion inspired by ESPIRiT), can be related to a convex relaxation of the NLINV problem subject to a low-rank constraint. From NLINV, it inherits its suitability for calibrationless and non-Cartesian imaging; from ESPIRiT it inherits robustness to data inconsistencies.

5161

Computer 54 [Feature Refinement Scheme for Improved STEP Parallel Imaging Reconstruction](#)

Zechen Zhou¹ and Chun Yuan^{2,3}

¹Philips Research China, Shanghai, People's Republic of China, ²Vascular Imaging Lab, Department of Radiology, University of Washington, WA, United States, ³Center for Biomedical Imaging Research, Department of Biomedical Engineering, Tsinghua University, Beijing, People's Republic of China

In this work, we incorporated the Feature Refinement (FR) scheme into the Self-supporting Tailored k-space Estimation for Parallel imaging reconstruction (STEP) image reconstruction framework to enhance its capability for structural representation in image domain, and developed a novel Weber Local Descriptor (WLD) method to improve the extraction of local image boundaries. With the preliminary experiments, it has been demonstrated that the improved STEP with WLD FR scheme can provide more accurate estimation of image details in comparison to original STEP and existing classic method.

A new pattern for Autocalibrated Parallel Imaging Reconstruction for GRASE: APIR4GRASE

Chaoping Zhang¹, Alexandra Cristobal-Huerta², Juan Antonio Hernández-Tamames², Stefan Klein¹, and Dirk H.J. Poot^{1,2,3}

¹Departments of Medical Informatics and Radiology, Erasmus MC, Rotterdam, Netherlands, ²Departments of Radiology and Nuclear Medicine, Erasmus MC, Rotterdam, Netherlands, ³Imaging Science and Technology, Delft University of Technology, Delft, Netherlands

We propose a subsampled interleaved parallel acquisition pattern for Autocalibrated Parallel Imaging Reconstruction for GRASE (APIR4GRASE) which considers different echoes during each refocusing of the GRASE as if they originated from different coil channels. APIR4GRASE eliminates ghosting artifacts caused by the phase and amplitude modulations in traditional GRASE split sampling pattern and achieves an additional acceleration factor of 1.3 compared to a fully sampled GRASE k-space. In addition, multiple contrast (spin echo and gradient echo) images are reconstructed. Experiments on a phantom demonstrate the effectiveness of our method.

Improved Parallel Imaging with Resilience to Gradient Errors

Gigi Galiana¹ and Nadine Luedicke²

¹Radiology and Biomedical Imaging, Yale University, New Haven, CT, United States, ²Biomedical Engineering, Yale University, New Haven, CT, United States

FRONSAC encoding, which adds a rapidly oscillating low-amplitude nonlinear gradient to a standard undersampled trajectory based on linear gradients, has been shown to significantly improve k-space coverage and parallel imaging reconstructions. This abstract further shows that a fixed FRONSAC waveform improves image quality for Cartesian trajectories of various FOV and resolution, while avoiding many of the pitfalls of other highly efficient gradient trajectories. Results show that FRONSAC provides better reconstruction than Cartesian encoding alone, while offering better resilience to delays and off-resonance effects than non-Cartesian trajectories, such as spiral.

Computer 57

Accelerated MR cardiac cine using TSPiRiT with generalized data fidelity

Yilong Liu^{1,2}, Mengye Lyu^{1,2}, and Ed X. Wu^{1,2}

¹Laboratory of Biomedical Imaging and Signal Processing, The University of Hong Kong, Hong Kong, People's Republic of China, ²Department of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, People's Republic of China

MR cardiac cine plays a key role in quantifying the cardiac function. The measurement accuracy is highly dependent of both spatial and temporal resolution, which can be improved substantially by acceleration with parallel imaging. SPIRiT, a GRAPPA-like parallel imaging reconstruction, can be applied to cardiac cine by incorporating temporal sensitivity estimation (TSPiRiT). In this study, we propose to enhance MR cardiac cine using TSPiRiT with generalized data fidelity (GDF) based on the assumption that k-space signal in cardiac cine changes smoothly. Results show that the proposed method can provide better tradeoff between SNR and temporal resolution when compared with TSPiRiT and k-t SPIRiT.

5165

Computer 58

Improved SPIRiT Operator for Joint Reconstruction of Multiple T2-weighted Images

Toyyan Kilic^{1,2}, Efe Ilıcak^{1,2}, Tolga Çukur^{1,2}, and Emine Ulku Saritas^{1,2}

¹Electrical and Electronics Engineering, Bilkent University, Ankara, Turkey, ²National Magnetic Resonance Research Center, Bilkent University, Ankara, Turkey

Recently, compressed-sensing (CS) was proposed to jointly reconstruct undersampled multi-contrast datasets to exploit the common structural features therein. Here, we propose a method to improve joint reconstruction of multi-contrast acquisitions. Inspired by the SPIRiT framework for parallel imaging, our method linearly synthesizes missing data for each contrast from neighboring k-space data for all contrasts. To improve reconstruction quality, the proposed method high-pass filters calibration data to emphasize the weight of intermediate spatial frequencies in the interpolation operator. Phantom and in vivo results at 3T indicate that the proposed method outperforms reconstructions with conventionally estimated interpolators.

5166

Computer 59

Nonlinear SPIRiT using a second order virtual coil for improved parallel imaging reconstruction

Sen Jia¹, Yanjie Zhu¹, Lei Zhang¹, Yiu-cho Chung¹, Jing Cheng¹, Leslie Ying², Xin Liu¹, Hairong Zheng¹, and Dong Liang¹

¹Shenzhen Institutes of Advanced Technology, Shenzhen, People's Republic of China, ²The state University of New York (SUNY) at Buffalo, United States

The nonlinear relationship between missing and acquired data in k-space has been proved in nonlinear GRAPPA. In this work, we propose nonlinear SPIRiT which integrates the polynomial kernel method into SPIRiT via a simple second-order virtual coil approach. The proposed method represents the relationship between missing and acquired data in k-space of SPIRiT using a more accurate nonlinear model. In vivo results demonstrated that nonlinear SPIRiT could suppress aliasing artifact or noise better than SPIRiT, and was applicable to more acceleration scenarios than nonlinear GRAPPA.

Computer 60

Impact of FLASH based autocalibration scans on high-resolution GRAPPA accelerated EPI at 7T

Joelle E Sarlls¹ and S. Lalith Talagala¹

¹NINDS/NMRF, National Institutes of Health, Bethesda, MD, United States

It has been shown that the temporal SNR (tSNR) of GRAPPA EPI can be improved by using different autocalibration scan (ACS) acquisitions. We evaluated the impact of using FLASH-ACS for high resolution, GRAPPA accelerated EPI at 7T. We compared the tSNR, ghost levels and distortions characteristics of EPI data reconstructed using SSEPI, MSEPI and FLASH based ACS at different acceleration factors and resolutions. Results showed that the tSNR of GRAPPA accelerated EPI improved by 60-100% when using FLASH-ACS data during image reconstruction. FLASH-ACS reconstructions also had less residual EPI ghost and identical image distortions compared to SSEPI-ACS and MSEPI-ACS.

5168

Computer 61

Accelerating T2* Mapping with Maximum Likelihood Estimation (MLE) and Parallel Imaging (PI)

Wajiha Bano^{1,2}, Arnold Julian Vinoj Benjamin^{1,2}, Ian Marshall², and Mike Davies¹

¹Institute for Digital Communication, University of Edinburgh, Edinburgh, United Kingdom, ²Centre for Clinical Brain Sciences, University of Edinburgh, Edinburgh, United Kingdom

The utility of MR parametric mapping is limited due to the lengthy acquisition time. A Maximum Likelihood Estimation (MLE) and Parallel Imaging (PI) method is presented for MR parametric mapping. The approach is based on a high Signal to Noise ratio (SNR) assumption such that the noise can be modelled as Gaussian and estimates the parameters that maximizes the signal from a multichannel coil. The method was tested on a multi-echo gradient-echo T2* mapping experiment in a phantom and a human brain. Accurate T2* maps were reconstructed up to an acceleration factor of 6 with a small error for phantom and human brain.

5169

Computer 62

A Novel Method to Increase SNR of GRAPPA Reconstruction

Yu Ding¹, Renjie He¹, Qi Liu¹, Renkuan Zhai², Guobin Li², Jian Xu¹, and Weiguo Zhang²

¹UIH America, Inc., Houston, TX, United States, ²Shanghai United Imaging Healthcare Co., Ltd, Shanghai, People's Republic of China

We propose a novel method to improve GRAPPA reconstruction when blood vessel pulsation artifacts appear. It removes the artifacts in the ACS lines, and boosts the SNR of GRAPPA reconstruction. Volunteer study confirmed that the proposed method improved image quality of GRAPPA reconstruction in 3T FSE knee scan.

SPID Compressed Sensing for Parallel MRI: Flexible Sampling and Rapid Reconstruction

Efrat Shimron¹, Andrew G. Webb², and Haim Azhari¹

¹Biomedical Engineering Department, Technion - Israel Institute of Technology, Haifa, Israel, ²C.J. Gorter Center for High Field MRI Research, Department of Radiology, Leiden University, Leiden, TN, Netherlands

We introduce a new method combining Compressed Sensing (CS) and parallel MRI (pMRI) for fast MRI acquisition. The method, termed SPID-CS, is advantageous over existing methods since it (1) produces a high-quality initial reconstruction, (2) avoids aliasing related to sub-Nyquist sampling by joining information from different coils, (3) enables flexible k-space sampling, (4) converges much faster than conventional CS and (5) enables clinical real-time reconstruction due to its extremely short runtime.

5171

Computer 64

Alias-reduced multicoil single-shot spatially temporally encoded MRI with referenceless sensitivity encoding

Ying Chen¹, Lisha Yuan¹, Yi Sun², and Jianhui Zhong¹

¹Center for Brain Imaging Science and Technology, Zhejiang University, Hangzhou, People's Republic of China, ²MR Collaboration Northeast Asia, Siemens Healthcare, Shanghai, People's Republic of China

Single-shot spatiotemporally encoded (SPEN) MRI is a novel fast imaging scheme with remarkably reduced geometric distortions at high field compared to conventional single-shot EPI. The k-space along SPEN dimension is undersampled, resulting in aliases at regions of rapid profile variation. The feasibility of utilizing sensitivity profiles of array receiver coils to unravel the undersampling aliases is investigated. High resolution relative sensitivity profiles can be obtained from multicoil 2D polynomial fitting of the SPEN reconstructed images without additional reference scans. The effectiveness of the SPEN SENSE strategy is validated by healthy human brain scans at 3T.

5172

Computer 65

Enhancing resolution in single-shot MRI by Super-resolved SPEN with SENSE (SUSPENSE)

Gilad Liberman¹, Eddy Solomon¹, Michael Lustig², and Lucio Frydman¹

¹Chemical Physics, Weizmann Institute of Science, Rehovot, Israel, ²Department of Electrical Engineering and Computer Sciences, Berkeley, CA

Spatio-temporal encoding (SPEN) delivers single-scan images with increased robustness to shift and susceptibility artifacts. These acquisitions are usually carried out in a "hybrid" mode that prevents a sufficiently dense sampling along the SPEN domain. Alleviating this resolution loss had so far demanded the acquisition of multiple interleaved scans. The present study demonstrates that by relying on multiple sensors, a similar resolution enhancement can be achieved in a single shot. The principles and potential of the ensuing Super-resolved SPEN with SENSE (SUSPENSE) is demonstrated, with sub-mm single-shot 3T image acquisitions on phantoms and humans.

5173

Computer 66

Spiral SENSE MP-RAGE using long readouts and an expanded signal model

Franciszek Hennel¹, Maria Engel¹, Lars Kasper¹, Bertram Wilm¹, and Klaas P Pruessmann¹

¹Institute for Biomedical Engineering, ETH and University of Zurich, Zurich, Switzerland

Spiral readout was used to accelerate the standard T1-weighted 3D head scan based on MPRAGE at 3 Tesla without any compromise on images quality. The encoding model used by the reconstruction included the static magnetic field map as well as the k-space trajectory and a dynamic field correction provided by a field camera. The study demonstrates the utility of state-of-the-art spiral scanning for routine MRI applications.

5174

Computer 67

GRAPPA Reconstructed Wave-CAIPI MPRAGE at 7 Tesla

Jolanda Melissa Schwarz¹, Daniel Brenner¹, Eberhard Daniel Pracht¹, and Tony Stoecker¹

¹German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany

In this work, a GRAPPA-based reconstruction for wave-CAIPI acquisitions is presented. 16-fold accelerated full brain MPRAGE images with 1 mm isotropic resolution and high image quality are measured in 45 seconds and a clear improvement compared to Cartesian CAIPIRINHA sampling can be observed. It is demonstrated that optimization of the gradient waveforms further improves image quality.

5175

Computer 68

Combined Application of GRAPPA and POCS for Fast MR Image Reconstruction

Hassan Shahzad^{1,2} and Hammad Omer³

¹Electrical Engineering, COMSATS Institute Of IT, Rawalpindi, Pakistan, ²National Center for Physics, Islamabad, Pakistan, ³COMSATS Institute Of IT, Islamabad, Pakistan

The proposed work presents a combination of GRAPPA and Compressed sensing (POCS) to reconstruct MR images from the highly under-sampled data. Firstly, GRAPPA is applied to the acquired under-sampled data. The output of GRAPPA which contains aliasing artifacts (especially for high acceleration factors) is fed in to POCS which solves for the solution image iteratively and produces a reconstructed image with minimal aliasing artifacts. The reconstruction results are compared with GRAPPA and POCS separately. The results show that the proposed method significantly reduces the aliasing artifacts as compared to GRAPPA or POCS reconstructions.

5176

Computer 69

Influence of temporal resolution on liver perfusion using golden-angle radial sparse parallel MRI

Nikolaos S Kallistis¹, Kai Tobias Block², Robert Grimm³, Hersh Chandarana², Ian Rowe¹, and Steven P Sourbron⁴

¹Leeds Institute of Biomedical and Clinical Sciences, University of Leeds, Leeds, United Kingdom, ²School of Medicine, New York University, New York, NY, United States, ³Siemens AG Healthcare MR, Erlangen, Germany, ⁴Leeds Institute of Cardiovascular and Metabolic Medicine, University of Leeds, Leeds, United Kingdom

Golden-angle radial sparse parallel (GRASP) MRI uses temporal regularization in the reconstruction, which risks distorting temporal profiles and reducing DCE-MRI parameter accuracy and precision. The aim of this study is to investigate this issue for liver DCE-MRI by measuring kinetic parameters on data reconstructed at variable temporal resolution. The results depend on temporal resolution according to well-known patterns also observed in simulations and fully sampled data. A systematic error remains at the highest temporal resolution, but this is more likely due to well-known issues of signal saturation. Image reconstruction at lower temporal resolution risks degrading diagnostic image quality due to the mixing of images with different contrast. We conclude that: (1) temporal regularization in GRASP is unlikely to induce significant error in kinetic parameters; (2) images should be reconstructed at high temporal resolution around 2-4s.

5177

Computer 70

Absolute B₁- estimation without a homogeneous receive coil

Olivia W Stanley^{1,2}, Ravi S Menon^{1,2}, and L Martyn Klassen²

¹Department of Medical Biophysics, The University of Western Ontario, London, ON, Canada, ²Centre for Functional and Metabolic Mapping, The University of Western Ontario, London, ON, Canada

Fitting the relative B₁- maps derived from a B₁+ shim acquisition to the Helmholtz equations allows for the calculation of absolute B₁- maps. The sensitivity profiles can then be used to optimally combine coils in subsequent acquisitions. In addition, absolute B₁- maps allow for the removal of the receive sensitivity from the combined images. This was validated in a GE-EPI sequence and found to produce images with lower phase standard deviation and increased temporal signal-to-noise ratios across the brain. Both of these differences were found to be statistically significant in a Student's t-test.

5178

Computer 71

The Signal-to-Noise Behavior of 3D SPIRiT Image Reconstruction

Yulin V Chang¹, Marta Vidorreta², and John Detre²

¹National Institutes of Health, Bethesda, MD, United States, ²Neurology, University of Pennsylvania, Philadelphia, PA, United States

Self-consistent parallel imaging (SPIRiT) is a self-calibrated, iterative parallel imaging technique that is not restricted by a particular k-space sampling pattern. 3D SPIRiT takes advantage of the 3D arrangement of a modern receive array to further improve image quality. Although SPIRiT was shown to yield higher image quality than does GRAPPA, especially at acceleration factors higher than 2, its signal-to-noise behavior has not been rigorously studied. In this study we investigate the image quality behavior of 3D SPIRiT and determine the optimal condition for best image quality.

5179

Computer 72

Intracranial artery vessel wall reconstruction via feature refinement

Jing Cheng¹, Sen Jia¹, Lei Zhang¹, Yanjie Zhu¹, Yuanyuan Liu¹, Leslie Ying², Xin Liu¹, Hairong Zheng¹, and Dong Liang¹

¹Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, People's Republic of China, ²Department of Electrical Engineering, The State University of New York (SUNY) at Buffalo, NY, United States

Depicting the vessel wall of intracranial arteries at high resolution and contrast is important to evaluate the intracranial artery disease. This paper propose a feature refinement strategy for improving the reconstruction quality of intracranial artery vessel wall by incorporating the feature descriptor into the reconstruction framework of L1-SPIRiT. Results on in vivo MR data have shown that the feature refinement method is capable of reconstructing the vessel wall with higher contrast than the method without feature refinement, and thus presents great potential for MR vessel wall imaging.

Computer 73

A novel method for Rapid 3D fat and water decomposition using a Globally Optimal multi-surface Estimation (R-GOOSE)
Chen Cui¹, Abhay Shah¹, Xiaodong Wu¹, Dan Thedens², and Mathews Jacob¹

¹Electrical and Computer Engineering, University of Iowa, Iowa City, IA, United States, ²Radiology, University of Iowa, Iowa City, IA, United States

A 3D Rapid, Globally Optimal Surface Estimation (R-GOOSE) algorithm for fat-water decomposition in MRI is proposed. The fat-water separation is formulated as an optimization problem with data consistency and field-map smoothness penalty. The data consistency only contains exact minimizers from the fully discretized field-map value volume. The proposed method employs a connectivity-reduced graph construction that enables the new formulation to be solved efficiently. The method is validated by the 17 datasets from the 2012 ISMRM Challenge with thirty-fold computational gain compared to our previous method GOOSE while the high quantitative accuracy is maintained. Fat fraction maps obtained from the proposed method also provides a good marker for degenerative muscle diseases in newly collected lower limb datasets.

Computer 75

Fat tissue mimics for validation of magnetic resonance thermometry

Slavka Carnicka¹, Kathryn Keenan¹, Elizabeth Mirowski², Mark Brown³, Christopher Suiter⁴, Tara Fortin⁴, Hannah Erdevig¹, Karl Stupic¹, and Stephen Russek¹

¹Physical Measurement Laboratory, National Institute of Standards and Technology, Boulder, CO, United States, ²High Precision Devices Inc., Boulder, CO, United States, ³Department of Radiology, University of Colorado School of Medicine, Denver, CO, United States, ⁴Applied Chemicals and Materials Division, National Institute of Standards and Technology, Boulder, CO, United States

Phase-based magnetic resonance thermometry is used for monitoring minimally invasive ablation therapies like focused ultrasound therapy. MRT is prone to errors when applied in tissues with high fat content (e.g. breast tissue, fatty liver) due to heat-induced susceptibility changes. Therefore, there is a need for developing well characterized adipose tissue mimics that could serve as standards for validation of MRT techniques. In this study we showed that all measured adipose tissue mimics are representative of human adipose tissue with similar chemical spectra and thermal dependence of susceptibility shift and are reproducible standards for human adipose tissue validation MRI techniques.

Classification of White and Brown Adipose Tissue using a Support Vector Machine

Brandon Campbell^{1,2}, Gregory Simchick^{1,2}, Hang Yin³, and Qun Zhao^{1,2}

¹Physics and Astronomy, University of Georgia, Athens, GA, United States, ²Bio-Imaging Research Center, University of Georgia, Athens, GA, United States, ³Biochemistry and Molecular Biology, University of Georgia, Athens, GA, United States

Determining the volume and distribution of white adipose tissue (WAT) and brown adipose tissue (BAT) by magnetic resonance imaging (MRI) is clinically important. Previous WAT and BAT classification has relied on using fat fraction and proton relaxation time via fixed multi-peak spectroscopic models. However, the recently proposed Multi-Varying-Peak MR Spectroscopy (MVP-MRS) model allows for the selection of appropriate classification features for differentiation between WAT and BAT. Furthermore, these multi-peak features allow prediction of a 'browning' or 'beiging' process of WAT by using a Support Vector Machine (SVM) learning algorithm.

5186

Computer 79

Quantitative Liver Fat Measurements in Obese Adolescents: Comparison between using MR Spectroscopy and Chemical-shift Water-fat Fat-fraction Techniques

Steve Cheuk Ngai Hui¹, David Ka Wai Yeung¹, and Winnie Chiu Wing Chu¹

¹Department of Imaging and Interventional Radiology, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Liver fat contents measured by magnetic resonance spectroscopy and chemical-shift water-fat separation imaging were compared in a group of obese adolescents. Distribution of fat in left and right liver lobes was also compared. Results demonstrated that fat contents obtained from both MR modalities were highly correlated and agreed to each other. In obese adolescents with non-alcoholic fatty liver disease, fat distribution was non-uniform between left and right lobes. This study supports the use of fat-fraction map to measure liver fat, which can shorten the scanning time by acquiring information about body adipose tissue and liver fat within a single sequence.

How accurately can fat be quantified? A Bayesian View

Xiaoli Wang¹, Li Xu², and Xiaoguang Cheng²

¹Philips Healthcare, Beijing, People's Republic of China, ²Department of Radiology, Beijing Jishuitan Hospital

An error analysis was carried, under frame work of Bayesian probability theory, for fat quantification using multiple gradient echo sequences to separate water and fat content in MRI signal. The results confirm that this method is accurate when protocols are carefully designed; this analysis also provides guideline in designing parameter settings to achieve optimal accuracy in fat quantification measurements.

Breast density (BD) is a risk factor for breast cancer, which makes the accurate measurement of BD a priority. Mammography is most widely used for BD determination (MG-BD) but ionizing radiation prohibits its use. BD derived from fat-water decomposition MRI (FWMRI-BD) has been proposed. Here we developed an optimized FWMRI-BD measurement (FraG+W) and compared it to MG-BD and a previous FWMRI-BD measurement (Fra80/90). Both FWMRI-BD measures were strongly correlated with MG-BD and exhibited superior test-retest reliability. The proposed automated FraG+W, which quantifies the entire fibroglandular and water content of the breast, is more accurate and reliable than the previous Fra80/90.

A new Phase Unwrapping Method Based on Wraps Identification and Local Surface Fitting for Water-Fat Separation

Junying Cheng^{1,2}, Yingjie Mei^{2,3}, Biaoshui Liu², Xiaoyun Liu¹, Wufan Chen^{1,2}, and Yanqiu Feng²

¹School of Automation Engineering, University of Electronic Science and Technology of China, Chengdu, People's Republic of China, ²School of Biomedical Engineering and Guangdong Provincial Key Laboratory of Medical Image Processing, Southern Medical University, Guangzhou, People's Republic of China, ³Philips Healthcare, Guangzhou, People's Republic of China

The phase information is widely used, for example water-fat separation, susceptibility imaging, etc. The phase-unwrapping methods are generally needed to estimate the underlying true phase from the principal period $(-\pi, \pi]$. While current phase-unwrapping methods are affected by noise, rapid phase change and disconnected regions. This paper presents an algorithm combined a wrapping identification scheme by thresholding the difference map between the local variations between phasor and wrapped phase, with the local polynomial surface fitting to merge the disconnected components and estimate the phase value of residual pixels in quality guidance region-growing way. The results demonstrate the proposed method provides an accurate and reliable unwrapped results and has potential application to phase-related MRI in practice.

Noise Properties of Proton Density Fat Fraction Estimated using Chemical Shift Encoded MRI

Nathan T Roberts^{1,2}, Diego Hernando^{1,3}, James H Holmes¹, Curtis N Wiens¹, and Scott B Reeder^{1,3,4,5,6}

¹Radiology, University of Wisconsin - Madison, Madison, WI, United States, ²Electrical & Computer Engineering, University of Wisconsin - Madison, Madison, WI, United States, ³Medical Physics, University of Wisconsin - Madison, Madison, WI, United States, ⁴Medicine, University of Wisconsin - Madison, Madison, WI, United States, ⁵Emergency Medicine, University of Wisconsin - Madison, Madison, WI, United States, ⁶Biomedical Engineering, University of Wisconsin - Madison, Madison, WI, United States

The purpose of this work was to characterize the noise distribution of proton density fat fraction estimation and provide alternatives to averaging for unbiased estimation. Monte-Carlo simulations and phantom experiments were used to validate the theoretically derived noise distribution. Results demonstrated that at low SNR, median and Nelder-Mead fitting algorithm estimators have reduced bias compared to the mean estimator.

Muscular fat fraction using high-resolution imaging – comparison of three T2-based methods and chemical shift-encoded imaging

Lena Trinh¹, Pernilla Peterson¹, Emelie Lind¹, Lars E Olsson¹, and Sven Månsson¹

¹Medical Radiation Physics, Department of Translational Medicine, Lund University, Skåne University Hospital, Malmö, Sweden

The most common method for fat-water separation nowadays is chemical shift-encoded imaging (CSEI). However, when studying fat accumulation in skeletal muscles and high spatial resolution fat fraction (FF) images are desired, CSEI might be challenging due to the increased inter-echo spacing. Here, three alternative methods based on T2-relaxation times, have been explored and compared to CSEI by calculating the muscular fat fraction of ten healthy volunteers. All T2-based methods resulted in qualitatively improved high-resolution FF images compared to CSEI, while a 2-parameter non-linear least square fit showed best quantitative agreement to low resolution CSEI.

5195

Improving the Noise Propagation Behavior of Different Fatty Acid Quantification Techniques using Spectral Denoising

Manuel Schneider¹, Felix Lugauer¹, Dominik Nickel², Brian M Dale³, Berthold Kiefer², Andreas Maier¹, and Mustafa R Bashir^{4,5}

¹Pattern Recognition Lab, Department of Computer Science, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, ²MR Applications Predevelopment, Siemens Healthcare GmbH, Erlangen, Germany, ³MR R&D Collaborations, Siemens Healthcare, Cary, NC, United States, ⁴Radiology, Duke University Medical Center, Durham, NC, United States, ⁵Center for Advanced Magnetic Resonance Development, Duke University Medical Center, Durham, NC, United States

MRI is not only capable of quantifying the fat content, but also the fatty acid composition of human adipose tissue. Especially for low fat fractions, fatty acid quantification is sensitive to image noise. Including prior information or additional parameter approximations into the quantification method helped to improve the noise propagation behavior, but also introduced a systematic bias. Performing spectral denoising in between image reconstruction and fatty acid quantification kept the systematic bias as well as the noise in the parameter maps low, and hence allows for more flexible protocol selection and shorter acquisition times.

Computer 90

Flexible spin echo triple echo Dixon (flexible STED) for fat suppressed T1-weighted imaging

Jong Bum Son¹, Colleen Costelloe¹, Ken-Pin Hwang¹, Tao Zhang², Ersin Bayram², John Hazle¹, and Jingfei Ma¹

¹The University of Texas MD Anderson Cancer Center, Houston, TX, United States, ²GE Healthcare, WI, United States

The conventional spin-echo (SE) sequence produces the best available T1-contrast and is often used for imaging of brain, head and neck, and spine. Unfortunately, the inclusion of fat suppression pulses in an SE acquisition substantially reduces the number of slices per TR and therefore the overall scan efficiency. In this work, we developed a flexible spin-echo triple-echo Dixon (flexible STED) technique that enables SE Dixon imaging with high efficiency. The feasibility of the technique is demonstrated with in vivo post-contrast fat-suppressed T1-weighted imaging of spine.

Computer 91

MRI Quantification of Liver Proton Density Fat Fraction during Free Breathing using a Motion-Insensitive Single-Shot 2D Technique

B. Dustin Pooler¹, Jeannine A. Ruby¹, Diego Hernando¹, Ann Shimakawa², and Scott B. Reeder¹

¹University of Wisconsin, Madison, WI, United States, ²GE Healthcare, Waukesha, WI, United States

Chemical shift encoded (CSE-MRI) techniques have been previously validated for the measurement of liver proton density fat fraction (PDFF), which serves as a biomarker for liver fat content. However, current CSE-MRI techniques rely upon 3D volumetric or 2D interleaved acquisitions, both of which are sensitive to motion and require the patient to suspend respiration. In this study, we demonstrate the feasibility of a "single shot" 2D sequential CSE-MRI technique to freeze motion. 2D sequential CSE-MRI demonstrates superior performance during free breathing when compared to 3D and 2D interleaved acquisitions.

5199

Computer 92

Measurement of spleen fat on MRI-proton density fat fraction arises from reconstruction of noise

Cheng William Hong¹, Gavin Hamilton¹, Catherine Hooker¹, Charlie C Park¹, Calvin Andrew Tran¹, Jeffrey Schwimmer², Scott B Reeder³, and Claude B Sirlin¹

¹Liver Imaging Group, Department of Radiology, University of California, San Diego, San Diego, CA, United States, ²Department of Pediatrics, Division of Pediatric Gastroenterology, Rady Children's Hospital, San Diego, CA, United States, ³Departments of Radiology, Medical Physics, Biomedical Engineering, Medicine, and Emergency Medicine, University of Wisconsin, Madison, Madison, WI, United States

Non-zero proton density fat fraction (PDFF) is commonly observed in the spleen on chemical-shift-encoded MRI. A prospective assessment in 42 research subjects with no visible fat peaks on MR spectroscopy demonstrated small amounts of splenic fat (PDFF up to 4%) using four different MRI-based fat fraction estimation techniques. These measurements were poorly correlated with each other, implying that fat measurements in spleen are likely artifactual rather than representing true splenic fat.

Comparison of MRI techniques for hepatic fat and iron quantification in the UK Biobank study

Chloe Hutton¹, Michael Gyngell¹, Matteo Milanese¹, and Michael Brady¹

¹Perspectum Diagnostics, Oxford, United Kingdom

We compared standard Dixon and T2* relaxometry with "IDEAL" for measuring liver proton density fat fraction (PDFF) and T2*, surrogate metrics for steatosis and iron burden respectively. Results in 118 UK Biobank study participants showed very good correlation between the two methods. Dixon PDFFs were consistently lower than IDEAL PDFFs, explained by the 20° flip angle used for Dixon, introducing a T1 bias and deviation from true PDFF values. Results also showed improved image quality for IDEAL, highlighting the strength of this technique to serve as a reliable and simultaneous biomarker of liver fat and iron overload.

Computer 95

Biased Fuzzy C means based intensity inhomogeneity correction for segmentation of abdominal fat in DIXON MR Images
Krishna Kanth Chitta¹, Bhanu Prakash KN¹, Suresh Sadananthan², and Sendhil Velan S¹

¹Laboratory of Molecular Imaging, Singapore Bioimaging Consortium, Singapore, Singapore, ²Singapore Institute for Clinical Sciences, Singapore

Uniform distribution of intensity values for a given tissue type is desirable for accurate segmentation and quantification. Factors like non-uniform static magnetic field, motion artifacts, and inconsistent RF coil sensitivity introduce intensity inhomogeneity during MR image acquisition. Several methods for intensity inhomogeneity correction are proposed in the literature. We explored the suitability of Biased fuzzy C-means (BFCM) correction for quantification of abdominal fat from Dixon images. In our study we formulated a new 2-pass, 2D (intra-slice and inter-slice) BFCM framework for improved segmentation and quantification of abdominal fat.

RF slice shimming at 7T with power control on a commercial 8-channel transmit coil

Christopher J. Mirfin¹, Stephen Bawden¹, Paul Glover¹, Penny A. Gowland¹, and Richard Bowtell¹

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom

We investigate the performance that can be achieved by applying volume and slice shimming on the commonly-used Nova 8-channel transmit/32-channel receive head coil, whilst controlling the total transmit power, as a proxy for global SAR. Under this constraint, our results suggest that shimming on individual axial slices can significantly improve the achievable B1 field uniformity (39.0% ± 3.9%) for the same transmit power as normal quadrature mode.

5205

Computer 99

Resolution Enhancement in Ultra-High Field 3D Echo-Planar Imaging Using a Planes-on-a-Paddlewheel with Asymmetric Readout Train (POP-ART) Trajectory

Daniel Stäb¹ and Markus Barth¹

¹The Centre for Advanced Imaging, The University of Queensland, Brisbane, Australia

3D planes-on-a-paddlewheel (POP) EPI is a non-Cartesian readout scheme realized by rotating EPI readout planes about the phase encoding axis. We show that the additional use of echo-asymmetry allows for significant improvements in spatial resolution without negative effects on echo-time, dropouts and distortions. The concept called POP-ART was evaluated at 7T. Whole brain images were obtained at a spatial resolution of 0.78x0.78x1.0mm³ within less than 1 minute by using an echo-asymmetry of only 28%. Being faster spoiled gradient-echo and providing resolutions not achievable by corresponding Cartesian EPI techniques, the trajectory is of interest for T2* weighted or quantitative susceptibility imaging.

Computer 100

Quantitative measurements of perivascular spaces at 7T, using a semi-automatic tracking method

JM Spijkerman¹, HJ Kuij², WH Bouvy³, MI Geerlings⁴, J Hendrikse¹, PR Luijten¹, and JJM Zwanenburg¹

¹Department of Radiology, University Medical Center Utrecht, Utrecht, Netherlands, ²Image Sciences Institute, University Medical Center Utrecht, Utrecht, Netherlands, ³Brain Center Rudolf Magnus, Department of Neurology, University Medical Center Utrecht, Utrecht, Netherlands, ⁴Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, Netherlands

Currently, perivascular spaces (PVS) are mostly investigated with qualitative measures. In this work, PVS in the centrum semiovale were tracked using a semi-automatic method, and PVS length and tortuosity were determined. Univariate and multivariate linear regression was performed for age, number of tracked PVS, PVS length, and PVS tortuosity. The results show that quantitative assessment of PVS beyond counting is feasible, and a significant positive association between PVS length and the number of tracked PVS was found. These quantitative measurements may be more suitable than qualitative methods to investigate PVS.

T1 Mapping of NIST Phantom at 7T

Yi-Fen Yen¹, Kathryn E. Keenan², Karl F. Stupic², Andre van der Kouwe¹, and Jonathan R. Polimeni^{1,3,4}

¹Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Charlestown, MA, United States, ²Physical Measurement Laboratory, National Institute of Standards and Technology (NIST), Boulder, CO, United States, ³Harvard-MIT Division of Health Sciences and Technology, Massachusetts Institute of Technology, Cambridge, MA, United States, ⁴Department of Radiology, Harvard Medical School, Boston, MA, United States

We are reporting quantitative T1 values of the NIST T1 phantom at 7T for the first time by using IR-SE method. We also compared the accuracy of T1 mapping by using MP2RAGE and variable flip angle (VFA) methods against the IR-SE T1s at 7T and found MP2RAGE gave more accurate T1 measure than VFA, for T1 of 300 ms to 2000ms (the range of brain T1). Although the accuracy of MP2RAGE at 7T was not as good as that at 3T (also shown), MP2RAGE is a promising technique for accurate brain T1 mapping at 7T within a clinically acceptable scan time.

Slice-wise first-order shimming of the human spinal cord at 7T

S. Johanna Vannesjo¹, Yuhang Shi¹, Irene Tracey¹, Karla L. Miller¹, and Stuart Clare¹

¹FMRIB centre, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom

Spinal cord imaging would benefit from the SNR increase at ultra-high field, to depict small structures inside the cord. However, higher background field strengths also increase susceptibility-induced B_0 field distortions, causing image distortions and signal dropouts. To improve field homogeneity, we here implement slice-wise first-order shimming in the cervical spinal cord at 7T. The slice-wise shim settings were calculated based on a B_0 field map and a semi-automatically generated spinal cord mask. We demonstrate that the slice-wise shims can improve signal levels in a high-resolution anatomical multi-echo GRE sequence.

5211

Computer 105

Gradient Moment Dependent T2 Accuracy in FISP Magnetic Resonance Fingerprinting (MRF) at 7T

Christian Anderson¹, Charlie Wang¹, Yuning Gu¹, Yun Jiang¹, Dan Ma², Mark Griswold^{1,2}, Xin Yu^{1,2,3}, and Chris Flask^{1,2,4}

¹Biomedical Engineering, Case Western Reserve University, Cleveland, OH, United States, ²Radiology, University Hospitals Cleveland Medical Center, Cleveland, OH, United States, ³Physiology and Biophysics, Case Western Reserve University, Cleveland, OH, United States, ⁴Pediatrics, University Hospitals Cleveland Medical Center, Cleveland, OH, United States

Magnetic Resonance Fingerprinting allows for rapid, simultaneous multi-parametric quantification. The use of a FISP imaging kernel is necessary due to field inhomogeneity in human body and preclinical imaging. We have observed that increases in the applied gradient moment lead to gradient moment size dependent changes in T2 accuracy. By examining different applied gradient moments we illustrate this loss of T2 accuracy while T1 measurement accuracy is maintained. This has implications for FISP MRF design and the implementation of unbalanced gradient moments for quantification.

Test-Retest Evaluation Spontaneous fMRI Signal: HCP 7T Reliability

Xi-Nian Zuo¹, Yin-Shan Wang¹, Dan-Yang Sui¹, and Xiu-Xia Xing²

¹Chinese Academy of Sciences, Beijing, People's Republic of China, ²Beijing University of Technology, Beijing, People's Republic of China

We employed the test-retest HCP datasets scanned at both 3T and 7T scanners from a same group of 62 healthy adults to compare differences in common functional metrics of the human connectome between 3T and 7T rfMRI settings in terms of their regional variations, individual variability and test-retest reliability. Our findings revealed metric-specific differences in both spatial patterns and reliability between 3T and 7T scanners whereas 7T improves reliability of global metrics but reduces reliability of local metrics of the functional connectomes.

5213

Computer 107

An SNR analysis of DENSE at 7T vs 3T for the measurement of whole brain tissue pulsatility

Ayodeji L Adams¹, Peter R Luijten¹, and Jaco J.M Zwanenburg¹

¹Department of Radiology, University Medical Center Utrecht, Utrecht, Netherlands

Cardiac induced brain tissue pulsatility holds potential as a means to study the viscoelastic properties of the aging brain. In this study we measured the brain tissue motion in 8 healthy volunteers with DENSE at both 7T and 3T, and assessed the gain in SNR between field strengths. 4D SNR maps for both field strengths were made and examined with a robust histogram analysis. The mean SNR for all volunteers at 7T and 3T was 21.2 ± 6.3 and 7.1 ± 2.5 respectively. The higher SNR at 7T will likely yield greater accuracy in quantifying brain tissue pulsatility.

5214

Computer 108

Fluid and white matter suppression (FLAWS) with MP2RAGE sequence at 7T.

Yuta Urushibata¹, Hideto Kuribayashi¹, Junko Inoue¹, Tobias Kober^{2,3,4}, John Grinstead⁵, and Tomohisa Okada⁶

¹Siemens Healthcare K.K., Tokyo, Japan, ²Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, Switzerland,

³Department of Radiology, University Hospital (CHUV), Lausanne, Switzerland, ⁴LTS5, École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland, ⁵Siemens Medical Solutions, Inc., United States, ⁶Kyoto University, Kyoto, Japan

Fluid and white matter suppression (FLAWS) is a technique to suppress cerebrospinal fluid (CSF) and white matter (WM) using the MP2RAGE sequence, which has been introduced for 3T. In this study, FLAWS was applied at 7T and compared to a SPACE double inversion recovery (DIR). Inversion times of the sequences were optimized for volunteer brain images at 7T. FLAWS showed better suppression of CSF and WM, more homogeneous gray matter (GM) delineation, as well as better GM/WM contrast compared with DIR.

Computer 110

Pseudo-SSFP magnetic resonance fingerprinting (MRF) at 9.4T

Jinhyeok Choi¹ and Hyeonjin Kim^{1,2}

¹Department of Biomedical Sciences, Seoul National University, Seoul, Korea, Republic of, ²Department of Radiology, Seoul National University Hospital, Seoul, Korea, Republic of

A balanced steady-state-free-precession (bSSFP) sequence may be preferred in magnetic resonance fingerprinting (MRF) for its high SNR. However, as demonstrated recently at 3.0T, the echo formation in bSSFP is hindered by randomly varying flip-angles in a B₀-dependent manner, and yet, the destroyed spin-echo-like signal behavior can be restored by tailoring sequence timings according to varying flip-angles such that the spin ensemble is driven into a pseudo-steady-state. Given more severe B₀-inhomogeneity at high-field, we explored the efficacy of the pseudo-steady-state-free-precession (pSSFP) sequence in MRF (pSSFP-MRF) at 9.4T. Our results suggest that pSSFP-MRF has great potential for single-scan multiparameter mapping at high-field.

High Resolution Pseudo Continuous Arterial Spin Labeling (pCASL) of mouse brain at 9.4 Tesla

Sankar Seramani¹, Lydiane Hirschler², Emmanuel Luc Barbier², and Kuan Jin Lee¹

¹Laboratory of Molecular Imaging, Singapore Bioimaging Consortium, Singapore, Singapore, ²Université Grenoble Alpes, Grenoble Institut des Neurosciences, Grenoble, France

The objective of this study was to show the feasibility of performing ASL based high resolution perfusion imaging in the mouse brain at 9.4 Tesla. In this work we applied pCASL with phase optimization technique at the labeling plane to minimize the effect of B₀ inhomogeneity. We used fcFLASH based technique to measure the labeling efficiency of pCASL sequence and compared the labeling efficiency with FAIR ASL in mouse brain. Based on our results, with the proposed method of phase optimization, labelling slice can be placed away from the iso-center of the magnet. This will allow us to place the imaging slice at the isocenter, which has showed significant improvement in the image quality of the mouse brain at ultra-high field strengths.

5218

Computer 112

Comparison of pCASL and FAIR for measuring Renal Blood Flow (RBF) of mouse kidney at 9.4T

Sankar Seramani¹, Lydiane Hirschler², Boominathan Ramasamy¹, Sakthivel Sekar¹, Kishore Bhakoo¹, Emmanuel Luc Barbier², and Kuan Jin Lee¹¹Laboratory of Molecular Imaging, Singapore Bioimaging Consortium, Singapore, Singapore, ²Université Grenoble Alpes, Grenoble Institut des Neurosciences, Grenoble, France

Arterial Spin Labeling (ASL) is a non-invasive MRI technique which can be used to measure quantitative renal perfusion without the injection of contrast agents. The goal of this study is to compare the performance of pCASL with FAIR in measuring Renal Blood Flow in mouse kidney at Ultra High Field (UHF) MR. Based on our experimental results, pCASL based perfusion measurement shows similar reproducibility when compared to FAIR method. pCASL shows better SNR sensitivity and lower in ROI variation of RBF in the kidney when compared to FAIR based ASL method at 9.4 Tesla.

Computer 113

Spatial Resolution Analysis Comparing Density-Adapted and Conventional Projection Reconstruction in Chlorine-35 MRI at 9.4 T

Ruomin Hu¹, Matthias Malzacher¹, Mathias Davids¹, Andreas Neubauer¹, Simon Konstandin², and Lothar R. Schad¹¹Computer Assisted Clinical Medicine, Heidelberg University, Mannheim, Germany, ²MR-Imaging and Spectroscopy, University of Bremen, Bremen, Germany

³⁵Cl MRI has been of interest for both human and animal in vivo applications to visualise chloride homeostatic changes. In this study we performed measurements of resolution phantoms at an isotropic resolution of 0.490 and 0.326 mm using scanner-equipped ultrashort echo time 3D (UTE3D) and newly implemented density-adapted 3D projection reconstruction (DA-3DPR) sequences with subsequent spatial resolution analysis. DA-3DPR images with visibly higher SNR are capable of resolving both gross and fine structures with more reliable signal distributions and more consistent rendition of structure shapes. Moreover, penalty-free radial oversampling leads to more extended artefact-free regions, allowing for smaller FOVs and reduced measurement times.

5220

Computer 114

Initial implementation of magnetic resonance fingerprinting on a preclinical 14.1 T scanner

Yasuhiko Terada¹¹University of Tsukuba, Tsukuba, Japan

Magnetic resonance fingerprinting (MRF) is a technique that enables simultaneous quantification of tissue parameters in a single scan. So far, MRF has been realized mostly for clinical 1.5 T and 3 T scanners, and a preclinical 7 T scanner. Application to a higher field scanner is limited and challenging because of the increased sensitivity to system hardware imperfections, such as B₀ and B₁ inhomogeneities and slice-profile imperfection. In this study, we assessed the feasibility of the MRF approach in a preclinical, wide-bore 14.1 T system.

Computer 116

Cost-effectiveness analysis of mascara for eye-blink detection in ultra-high field MRI

Joep Wezel¹ and Jan-Willem M. Beenakker²¹Radiology, Leiden University Medical Center, Leiden, Netherlands, ²Ophthalmology, Leiden University Medical Center, Leiden, Netherlands

Mascara has been proposed as a simple approach to correct for eye-motion artefacts via detection of induced B₀ changes when blinking. In this study we measure the B₀ changes from 10 different types of mascara. We can differentiate three different categories of mascara, in which in violation of Murphy's law the cheapest brands result in the strongest B₀ field changes.

5223

Computer 117

Quantitative Evaluation of Micro-vessel Blood Flow in Subcortical Nuclei with High-resolution TOF-MRA at 7T

Xianchang Zhang^{1,2}, Qi Yang^{3,4}, Qingle Kong^{1,2}, Zhaoyang Fan³, Jing An⁵, Rong Xue^{1,2,6}, and Zihao Zhang¹

¹State Key Laboratory of Brain and Cognitive Science, Beijing MR Center for Brain Research, Institute of Biophysics, Chinese Academy of Sciences, Beijing, People's Republic of China, ²University of Chinese Academy of Sciences, Beijing, People's Republic of China, ³Biomedical Imaging Research Institute, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ⁴Xuanwu Hospital, Beijing, People's Republic of China, ⁵Siemens Shenzhen Magnetic Resonance Ltd., Shenzhen, People's Republic of China, ⁶Beijing Institute for Brain Disorders, Beijing, People's Republic of China

TOF-MRA at 7T ultra-high field has been proven to have advantages in imaging the perforating arteries originating from the middle cerebral artery. In this study, a novel method of VOI-based micro-vessel density measurement was developed to quantitatively assess the blood flow in subcortical nuclei. Using this technique, the vascular density (VD) of specific basal ganglia sub-regions can be evaluated. Preliminary results showed that VD values of specific nuclei were different among Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy (CADASIL) patients, stroke patients, and healthy volunteers. VOI-based micro-vessel density measurement may be useful in differentiating the etiology of cerebral small vessel diseases.

[3D FLAIR at 7T using Direct Signal Control](#)Arian Beqiri¹, Hans Hoogduin², Alessandro Sbrizzi², Joseph V Hajnal^{1,3}, and Shaihan J Malik¹

¹Biomedical Engineering and imaging Sciences, King's College London, London, United Kingdom, ²Image Sciences Institute, University Medical Centre Utrecht, Utrecht, Netherlands, ³Centre for the Developing Brain, King's College London, London, United Kingdom

3D-FLAIR imaging at 7T using a 3D Turbo Spin Echo (TSE) readout is a useful tool for assessment of neurological disorders. The method does however suffer from variation in signal homogeneity due to B_1^+ inhomogeneities making whole-brain coverage difficult.

In this work, image uniformity is improved by using Direct Signal Control (DSC). The DSC method uses predictions of echo amplitudes to compute optimized RF shims that vary on a pulse by pulse basis throughout the echo train with the aim of homogenising signal properties. Low signal in the centre of the brain and cerebellum is effectively recovered in multiple subjects.

[Quantitative CEST MRI using Image Downsampling Expedited Adaptive Least-squares \(IDEAL\) fitting](#)Iris Yuwen Zhou¹, Enfeng Wang², Jerry S Cheung¹, Xiaoa Zhang², Giulia Fulci³, and Phillip Zhe Sun¹

¹Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital and Harvard Medical School, Charlestown, MA, United States, ²Zhengzhou University, ³Department of Neurosurgery, Massachusetts General Hospital and Harvard Medical School, Charlestown, MA, United States

CEST MRI is sensitive to dilute metabolites with exchangeable protons, allowing tissue characterization in diseases such as acute stroke and tumor. CEST quantification using multi-Lorentzian fitting is challenging due to its strong dependence on image SNR, initial values and boundaries. Here we proposed an Image Downsampling Expedited Adaptive Least-squares (IDEAL) fitting algorithm that quantifies CEST images based on initial values from multi-Lorentzian fitting of iteratively less downsampled images. The IDEAL fitting provides smaller coefficient of variation and higher contrast-to-noise ratio at a faster fitting speed compared to conventional fitting. It revealed pronounced CEST contrasts in tumors which were not found using conventional method. The proposed method can be generalized to quantify MRI data where SNR is suboptimal.

[Adaptive combine reconstruction of sodium MRI data of breast and knee at 7 T: optimization and comparison to sum-of-square reconstruction.](#)Lenka Minarikova^{1,2}, Stefan Zbyn^{1,2,3}, Olgica Zaric^{1,2}, Stephan Gruber^{1,2}, Armin Nagel^{4,5}, and Siegfried Trattnig^{1,2}

¹High Field MR Centre, Department of Medical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria, ²Christian Doppler Laboratory for Clinical Molecular MR Imaging, Vienna, Austria, ³Research Unit of Medical Imaging, Physics and Technology, University of Oulu, Oulu, Finland, ⁴Institute of Radiology, University Hospital Erlangen, Erlangen, Germany, ⁵Division of Medical Physics in Radiology, German Cancer Research Centre (DKFZ), Heidelberg, Germany

In this work, adaptive combine (AC) reconstruction was optimized on breast and knee sodium MRI data, acquired with a 14-channel breast and a 15-channel knee coils. AC reconstruction was compared with the standard sum-of-square (SoS) reconstruction. The optimal reconstruction parameters were: the lowest interpolation factor of two and an overlap of the analysis block of two to eight pixels. Images reconstructed using the AC had lower noise floor when compared to the SoS. However, when a multichannel coil with low noise correlation between elements is used, the advantage of AC reconstruction decreases.

[High-Resolution fMRI of the visual system at 3T using Zoomed Excitation via Tx-SENSE](#)R. Allen Waggoner¹, Kenichi Ueno², Josef Pfeuffer³, Keiji Tanaka¹, and Kang Cheng^{1,2}

¹Laboratory for Cognitive Brain Mapping, RIKEN - BSI, Wako-shi, Japan, ²Support Unit for Functional Magnetic Resonance Imaging, RIKEN - BSI, Wako-shi, Japan, ³Application Development, Siemens Healthcare, Erlangen, Germany

Zoomed EPI with a transmit SENSE excitation was used to perform high-resolution fMRI of the human visual cortex at 3T. Tx acceleration was used to reduce the minimum TE by 6ms. BOLD responses were detected in the visual cortex with sub-millimeter in-plane resolution. A monocular stimulation paradigm was employed, and voxels displaying a left or right eye preference were detected, but ocular dominance columns were not apparent. These results show that using transmit SENSE at 3T with a 2-channel pTx system for high-resolution fMRI is possible, but would benefit from further steps to improve tSNR.

Computer 2

[Functional MRI of the auditory cortex: maintaining the steady-state in EPI for silent inter-volume delays with different durations](#)Manoj Shrestha¹, H. Sean Lee^{1,2}, Ulrike Nöth¹, and Ralf Deichmann¹

¹Brain Imaging Center (BIC), Goethe University Frankfurt, Frankfurt am Main, Germany, ²Max Planck Institute for Empirical Aesthetics, Frankfurt am Main, Germany

An fMRI sequence for studying the auditory cortex is proposed, allowing for the insertion of silent delays of variable duration between EPI volumes during which auditory stimuli may be presented. Signal steady state conditions are maintained via spin saturation at fixed time points before each EPI volume. The method was successfully tested in vivo, yielding reliable activation of the primary auditory cortex. Results also show that high saturation efficiency is required to avoid erroneous activation patterns in compartments with long T_1 , such as cerebrospinal fluid.

Identification of BOLD and non-BOLD components using Multi-Echo ICA analysis: is native space better than MNI space?
Jed Wingrove¹, Owen O'Daly¹, and Fernando Zelaya¹

¹Centre for Neuroimaging Sciences, IoPPN, King's College London, London, United Kingdom

This work looks to see the effects of analysing and de-noising resting state functional data in the native space in comparison to the conventional methodology which utilises the normalisation, by voxel interpolation and re-sampling, of images to a standard space. We sought to investigate these effects in rs-fMRI data collected in healthy volunteers and analysed with multi-echo ICA de-noising and seed based connectivity.

Computer 4

Dynamic functional connectivity using multi-band multi-echo EPI (M2-EPI) imaging for resting-state fMRI
Junjie Wu¹, Shiyang Chen², Ganesh Chand³, Kyle Pate¹, Amit Saindane¹, and Deqiang Qiu¹

¹Department of Radiology and Imaging Sciences, Emory University School of Medicine, Atlanta, GA, United States, ²Department of Biomedical Engineering, Georgia Institute of Technology & Emory University School of Medicine, Atlanta, GA, United States, ³Department of Medicine, Emory University School of Medicine, Atlanta, GA, United States

In this abstract, we evaluated dynamic functional connectivity (FC) using multi-band multi-echo EPI (M2-EPI) resting-state data, which has higher temporal resolution, less susceptibility related signal dropouts and better signal-to-noise ratio. Dynamic FC and its states can be observed using M2-EPI data. Reduced temporal variation in dynamic FC was found using M2-EPI data acquisition as compared to conventional single-shot EPI imaging. The use of M2-EPI BOLD imaging may help to better delineate the structure of resting-state functional networks.

Computer 5

High resolution resting-state functional MRI at 7 Tesla using RF parallel transmission

Xiaoping Wu¹, Edward J. Auerbach¹, An T. Vu², Steen Moeller¹, Keith Jamison¹, Sebastian Schmitter^{1,3}, Pierre-Francois Van de Moortele¹, Essa Yacoub¹, and Kamil Ugurbil¹

¹Radiology, University of Minnesota, Minneapolis, MN, United States, ²Center for Imaging of Neurodegenerative Diseases, VA Healthcare System, San Francisco, CA, United States, ³Physikalisch-Technische Bundesanstalt, Berlin, Germany

A major component of the Human Connectome Project (HCP) in the WU-Minn consortium is multiband-accelerated whole-brain resting-state functional MRI (rfMRI) at both 3T and 7T. Although providing better contrast and higher spatial resolutions, the 7T acquisition is compromised by RF nonuniformity. Here, we demonstrate the utility of RF parallel transmission (pTx) for 7T HCP-type rfMRI with 1.6-mm isotropic resolutions. Our results show that pTx can significantly enhance temporal SNR across the entire cortical surfaces and in many subcortical voxels relative to a CP-like-mode RF shimming mimicking single-transmit configurations, thereby holding great potential for acquiring high-quality, high-resolution and high-efficiency rfMRI data.

Quantitative assessment of cerebral venous oxygenation in mouse using T2-Relaxation-Under-Spin-Tagging (TRUST) MRI at 11.7T
Zhiliang Wei¹, Jiadi Xu¹, Peiyong Liu¹, Lin Chen¹, Wenbo Li¹, Peter van Zijl¹, and Hanzhang Lu¹

¹Department of Radiology, The Johns Hopkins University, Baltimore, MD, United States

Venous oxygenation level reflects the cerebral metabolic rate of oxygen and its measurement facilitates studies of animal models of diseases. We developed a non-invasive and non-contrast-agent method based on T2-Relaxation-Under-Spin-Tagging (TRUST) to quantify cerebral venous oxygenation in mice at 11.7T. A series of studies were performed to optimize key imaging parameters. This method may prove useful in studies of brain physiology and pathophysiology in animal models.

Susceptibility Artifact Correction for DBS-fMRI using a PSF Mapping-based Reversed Gradient Approach

Myung-Ho In¹, Shinho Cho¹, Yunhong Shu², Hoon-Ki Min^{1,2,3}, Matthew A. Bernstein^{2,3}, Oliver Speck^{4,5,6,7}, Kendall H. Lee^{1,3}, and Hang Joon Jo¹

¹Departments of Neurologic Surgery, Mayo Clinic, Rochester, MN, United States, ²Departments of Radiology, Mayo Clinic, Rochester, MN, United States, ³Departments of Physiology and Biomedical Engineering, Mayo Clinic, Rochester, MN, United States, ⁴Department of Biomedical Magnetic Resonance, Institute for Experimental Physics, Otto-von-Guericke University Magdeburg, Magdeburg, Germany, ⁵German Centre for Neurodegenerative Diseases (DZNE), Magdeburg, Germany, ⁶Leibniz Institute for Neurobiology, Magdeburg, Germany, ⁷Center for Behavioral Brain Sciences, Magdeburg, Germany

Deep brain stimulation (DBS) fMRI has been considered as an emerging tool in investigating the DBS mechanisms and corresponding clinical outcomes, but suffers from severe susceptibility artifacts near metallic electrodes and tissue/air boundaries. A recent study showed that point spread function (PSF) mapping-based reverse gradient approach has a potential to correct distortions even in gradient-echo echo-planar imaging (GE-EPI) images with opposite phase-encoding polarity using a PSF dataset. To minimize the susceptibility artifacts, in this study, we apply the PSF approach for DBS-fMRI in swine. The results demonstrate that this approach can be beneficial for improving the reliability of DBS-fMRI.

Mouse somatosensory fMRI at 9.4T using a single-shot Variable Refocusing Flip Angle 3D GRASE

Joonsung Lee¹, Hyun-Ji Shim^{1,2}, Hahnsung Kim³, Jungryun Lee¹, Sangwoo Kim¹, Jeong Pyo Son^{1,2}, Won Beum Jung^{1,3}, and Seong-Gi Kim^{1,2,3}

¹Center for Neuroscience Imaging Research, Institute for Basic Science, Suwon, Korea, Republic of, ²Department of Health Sciences and Technology, Samsung Advanced Institute for Health Sciences and Technology, Sungkyunkwan University, Suwon, Korea, Republic of, ³Department of Biomedical Engineering, Sungkyunkwan University, Suwon, Korea, Republic of

A single-shot variable flip angle (VFA) 3D GRASE imaging protocol was proposed for mouse somatosensory spin echo fMRI. Given echo-spacing of 24ms and echo train length of 8, 3D GRASE imaging parameters such as phase-encode schedule in partition direction and variable refocusing flip angles were designed to achieve pseudo-continuous signal modulation and effective TE of 40ms. BOLD fMRI experiments were performed using 9.4T MRI with ketamine anesthetized mice. For eight slice acquisition of electrical forepaw stimulation fMRI, the proposed single-shot VFA 3D GRASE protocol achieved higher tSNR, t-values and larger activation areas than conventional 2D SE-EPI.

Feasibility study of gradient echo recalled readout segmented EPI with VB-EPI for ultra-silent fMRI

Patrick Liebig^{1,2}, Robin Martin Heidemann², Bernhard Hensel¹, and David Porter³

¹University of Erlangen-Nuremberg, Erlangen, Germany, ²Siemens Healthcare GmbH, ³Fraunhofer MEVIS

We present an application of Variable-Blipped-EPI (VB-EPI) with readout-segmented EPI¹, which has possible benefits for functional Magnetic Resonance Imaging (fMRI) experiments. Acoustic noise is reduced by lowering the amplitude of the readout (RO) gradient, which is possible due to the RO segmentation, and by prolonging the duration of the phase encoding (PE) blips simultaneously. Even with standard Cartesian parallel imaging techniques, like Generalized Autocalibrating Partially Parallel Acquisitions (GRAPPA)², high resolution images can be obtained with high image quality.

5236

Computer 10

Comparison of Carotid Arterial Signal Automatically Extracted from fMRI Data and Pulse Oximetry

Jeff Gunter¹, Joshua Trzasko¹, Bret Borowski¹, and Clifford Jack, Jr.¹

¹Radiology, Mayo Clinic, Rochester, MN, United States

Using only imaging data from an fMRI time series carotid cardiac cycle information may be automatically extracted. By merging data across slices "faster than TR" sampling is achieved. The resulting time series agree with pulse oximetry (PO) data. The distribution of relative peak times between PO and fMRI has standard deviation of around 40ms. The fMRI data was quite reliable with cardiac signal observed for all but two of approximately 3000 seconds; PO data was much less reliable.

Computer 11

Motion-Robust Fetal Brain Imaging using Inner Echo Volumar Imaging

Rita G Nunes^{1,2,3}, Giulio Ferrazzi³, Anthony N Price³, Jana Hutter³, Andreia S Gaspar^{2,3}, Mary Rutherford³, and Joseph V Hajnal³

¹Institute for Systems and Robotics / Department of Bioengineering, Instituto Superior Técnico, Universidade de Lisboa, Lisbon, Portugal, ²Instituto de Biofísica e Engenharia Biomédica, Faculdade de Ciências, Universidade de Lisboa, Lisbon, Portugal, ³Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom

The first fetal functional MRI studies used standard 2D multi-slice Echo Planar Imaging acquisitions, relying on post-processing for addressing motion-related effects. To reduce motion sensitivity, the use of Echo Volumar Imaging (EVI) combined with localized excitation has previously been proposed, but the very heterogeneous maternal environment renders selective excitation extremely challenging. We explored a more robust method combining EVI with inner volume imaging. By obtaining selective excitation from a spin-echo, sensitivity to field inhomogeneity is decreased, and spurious contributions from maternal tissue can be avoided. The method was tested in an adult and demonstrated in fetal imaging in utero.

Multi-slice balanced SSFP is an excellent alternative to GE-EPI for rodent fMRI at ultra-high field

Ileana Ozana Jelescu¹, Olivier Reynaud¹, Analina Raquel da Silva¹, and Rolf Gruetter¹

¹Centre d'Imagerie Biomédicale, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

Balanced SSFP (bSSFP) can be used as an alternative to gradient-echo (GE)-EPI for BOLD fMRI when image distortions and signal drop-outs are severe at high field. However, on animal systems, 3D-bSSFP acquisitions have low temporal resolution due to limited acceleration options and single slice offers insufficient coverage. Here, we perform multi-slice bSSFP in a pseudo-steady-state and show that non-distorted BOLD fMRI activation maps can be obtained, with comparable performance to GE-EPI. Future work will focus on resting-state fMRI using bSSFP and on the exploration of bSSFP BOLD contrast mechanisms at 14 Tesla.

Improved functional connectivity between the ventromedial prefrontal cortex and amygdala with multi-echo EPI: a resting state analysis

Brice Fernandez¹, Laura Leuchs², Philipp G. Sämann², Michael Czisch², and Victor I. Spooemaker²

¹Applications & Workflow, GE Healthcare, Orsay, France, ²Neuroimaging Unit, Max Planck Institute of Psychiatry, Munich, Germany

EPI suffers from signal loss in the ventromedial prefrontal cortex (vmPFC), a region of special interest in affective neuroscience. Last year, we showed that Multi-echo EPI (MEPI) was performing better than EPI in the vmPFC using a fear conditioning task. In the present work, we used a seed in the vmPFC, derived from the fear conditioning data, for a seed-based analysis on resting-state data collected from the same subjects. We demonstrate that the additional vmPFC cluster extent detected in the fear conditioning task reflects anatomically/functionally relevant activation as it is connected to bilateral amygdala and to the default mode network.

Computer 14

A more accurate account of the effect of k-space sampling and signal decay on the effective spatial resolution in functional MRI

Denis Chaimow^{1,2} and Amir Shmuel^{3,4}

¹University of Tübingen, Tübingen, Germany, ²Center for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN, United States, ³Montreal Neurological Institute, McGill University, Montreal, QC, Canada, ⁴Center for Magnetic Resonance Research, University of Minnesota, MN, United States

We show that the magnitude PSF fails to accurately represent the true effects of k-space sampling and signal decay. As an alternative, we propose to model fMRI with separate MR sampling and signal decay effects. We approximate the latter as a convolution with a Gaussian PSF or, if the effect is that of high-pass filtering, as reversing the effect of a convolution with a Gaussian PSF. At 7T signal decay in SE has a moderate blurring effect (FWHM = 0.89 voxels). Gradient-Echo acts as a high-pass filter, reversing blurring with FWHM = 0.59 voxels.

Computer 15

SCITH Approach Reveals Stable Functional Connectivity

Zhan Xu¹, Guangyu Chen¹, and Shi-Jiang Li¹

¹Biophysics, Medical College of Wisconsin, Milwaukee, WI, United States

Current Multi-Echo fMRI approach can only acquire up to three echoes due to the fast T2* decay. We hypothesized that more echo will improve the capability of increasing the BOLD CNR and denoise accuracy, and we managed to acquire up to six echoes using our within TR keyhole based approach: SCITH. Our preliminary data showed increased BOLD CNR and resting-state functional connectivity(FC), less temporal FC fluctuation and more consistent inter-subject FC in the same population.

Computer 16

The clinical relevance of correcting susceptibility-related distortions in presurgical fMRI at 7 T

Pedro Lima Cardoso¹, Barbara Dymerska¹, Beáta Bachratá¹, Florian Ph.S. Fischmeister^{1,2}, Nina Mahr^{1,2}, Eva Matt^{1,2}, Siegfried Trattnig¹, Roland Beisteiner^{1,2}, and Simon Daniel Robinson¹

¹High Field Magnetic Resonance Centre, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, Austria, ²Study Group Clinical fMRI, Department of Neurology, Medical University of Vienna, Vienna, Austria

The clinical relevance of correcting susceptibility-related distortions using a recently-developed dynamic distortion correction (DDC) approach is assessed. This was applied in fMRI data acquired from a group of 12 patients with a range of neuropathologies at 7 T. Despite the presence of pathologies, time series of artifact-free field maps were generated. If distortion correction was neglected, substantial displacements, both in EPI geometry and activation, were observed. Two cases with potential clinical implications were identified. The DDC was able to accurately correct distortions in all cases and is shown to be effective and clinically relevant in presurgical planning at 7 T.

Computer 17

Characterization of laminar profiles in human auditory cortex using a dense 24-channel temporal lobe array at 3T

Pu-Yeh Wu¹, Ying-Hua Chu¹, Jo-Fu Lotus Lin¹, Shang-Yueh Tsai², Wen-Jui Kuo³, and Fa-Hsuan Lin^{1,4}

¹Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ²Institute of Applied Physics, National Chengchi University, Taipei, Taiwan, ³Institute of Neuroscience, National Yang Ming University, Taipei, Taiwan, ⁴Department of Neuroscience and Biomedical Engineering, Aalto University, Espoo, Finland

By using a dedicated 24-channel temporal lobe array and surface based laminar depth analysis, we revealed the tonotopic representations in the human primary auditory cortex on a 3T MRI system. We found that, compared to deep and superficial layers, the minimal inter-subject variability of the tonotopic representation and frequency tuning width were found at the middle layer. Locations in the auditory cortex with finer frequency tuning had smaller inter-subject variability. Taken together, our findings suggested that middle layer of the auditory cortex has more specific frequency preference and selectivity, consistent with neurophysiological animal studies.

5244

Computer 18

Segmented EPI reconstruction based on physiological information for fMRI studies

Guoxiang Liu¹ and Takashi Ueguchi¹

¹National Institute of Information and Communications Technology, Suita-shi, Osaka, Japan

We proposed a new segmented EPI reconstruction method based on physiological information to reduce influence of physiological noise. A human brain was scanned on a 7T MRI scanner using segmented EPI, while recording cardiac pulse and respiration data. Our results showed that the proposed reconstruction method can reduce the respiratory-related and cardiac-related signal changes in fMRI studies.

Prospective Motion Correction of Multi-Band Multi-Echo fMRI During Overt Speech to Localize the Language Network

Prantik Kundu¹, Joao Correia², Saadi Ghatan³, Daniel Samber⁴, Michael Herbst⁵, and Benedikt A Poser²

¹Radiology and Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, United States, ²Cognitive Neuroscience, Maastricht University, ³Neurosurgery, St. Lukes Roosevelt Hospital Center, New York, NY, ⁴Radiology, Icahn School of Medicine at Mount Sinai, New York, NY, United States, ⁵University Hospital Freiburg, Freiburg, Germany

The functional localization of language and other clinically relevant brain networks at the subject-level has been limited by fMRI artifacts such as head motion. These artifacts have forced task-based fMRI for functional localization to be designed around strict timing and strong constraints, such as silent reading in 20-second task-rest blocks. Such limits make experiments hard to follow by patients and not ecologically valid. Dealing with these artifacts, especially at patient level, has been challenging with standard fMRI methods. Here we combine the acquisition technologies of multi-echo fMRI, multi-band acceleration, camera-based prospective motion correction, and 7T MRI, to image canonical language and other networks during overt speech with 7T MRI using stimuli with complex language content with naturalistic timing.

5247

¹Department of Physics, University of Pisa, Pisa, Italy, ²Imago7 Research Center, Pisa, Italy, ³Department of Neurologic Surgery, Mayo Clinic, Rochester, MN, United States, ⁴Biomedical Magnetic Resonance, Otto-von-Guericke University, Magdeburg, Germany, ⁵GE Healthcare, Pisa, Italy, ⁶IRCCS Stella Maris, Pisa, Italy, ⁷Leibniz Institute for Neurobiology, Magdeburg, Germany, ⁸Center for Behavioral Brain Sciences, Magdeburg, Germany, ⁹German Center for Neurodegenerative Diseases, Magdeburg, Germany

Distortion correction is an essential step for anatomically faithful analysis of ultra-high-field fMRI data due to strong susceptibility-induced geometric distortions in echo-planar imaging (EPI). Although the point-spread-function (PSF) method allows accurate unwarping and increase in SNR, its effectiveness in modulating the undistorted BOLD signal is still unknown. In this study we applied the PSF-based distortion correction using different types of correction kernels to GRE- and SE-EPI data at different resolutions and directly to the BOLD contrast maps, and evaluated the effectiveness by assessing functional contrast, specificity, and false-positive-rate.

Computer 22

Poloxamer: a new means to recover functional network information in the rodent's deep brain structures

Georges Hankov^{1,2,3,4}, Giovanna Diletta Ielacqua^{1,4}, Basil Künnecke², Thomas Mueggler², Markus von Kienlin², and Markus Rudin^{1,3,4}

¹Institute for Biomedical Engineering, ETH and University Zurich, Zurich, Switzerland, ²Roche Pharma Research & Early Development, Neuroscience Discovery, Roche Innovation Center Basel, F. Hoffmann-La Roche Ltd, Basel, Switzerland, ³Neuroscience Center Zurich, Zurich, Switzerland, ⁴Institute of Pharmacology and Toxicology, University of Zurich, Zurich, Switzerland

In the past years, functional MRI studies in rodents have become more frequent. The signal losses in gradient-echo EPI due to the increased sensitivity to magnetic susceptibility differences at higher magnetic field, however, make fMRI studies of deep brain structures difficult. Here we propose the use of Poloxamer, a non-toxic amphiphilic triblock copolymer well known for its thermo-reversible properties and pharmaceutical application to fill up the air cavities in the rodent middle and external ear canals. This practical method considerably increases geometric fidelity of the functional images, opening up the possibility to longitudinally investigate rodent's deep brain networks.

5249

Computer 23

PRESTO: an alternative to EPI for functional-MRI in rodents

Georges Hankov^{1,2,3,4}, Basil Künnecke², Markus Rudin^{1,3,4}, and Markus von Kienlin²

¹Institute for Biomedical Engineering, ETH and University Zurich, Zurich, Switzerland, ²Roche Pharma Research & Early Development, Neuroscience Discovery, Roche Innovation Center Basel, F. Hoffmann-La Roche Ltd, Basel, Switzerland, ³Neuroscience Center Zurich, Zurich, Switzerland, ⁴Institute of Pharmacology and Toxicology, University of Zurich, Zurich, Switzerland

With the increasing need for translational readouts, the number of fMRI studies in rodents has grown exponentially in the recent years. Nonetheless, methodological questions regarding fMRI data acquisition in small animals yet have been poorly addressed. In this work, we evaluate the use of the PRESTO sequence for fMRI in rodents: a 3D alternative to EPI using echo-shifting and echo-trains minimizing distortions and artefacts related to the higher magnetic fields, while providing better brain coverage and faster temporal resolution, allowing appropriate physiological noise sampling.

Computer 24

Increased BOLD activation with high degree spherical harmonic shimming at 7T

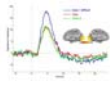

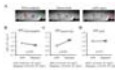

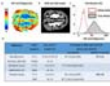

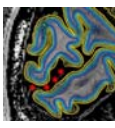

Tae Kim¹, Yoojin Lee¹, Tiejun Zhao², Hoby P Hetherington¹, and Jullie W Pan¹

¹University of Pittsburgh, Pittsburgh, PA, United States, ²Siemens, Pittsburgh, PA, United States

B₀ shimming is important for gradient echo functional MRI where T₂^{*} signal loss and precession occur from both physiological and non-physiological susceptibility effects. We used the high degree shim insert (3rd, 4th and two 5th degree shims) to assess its effect for 2mm isotropic whole brain GE-EPI BOLD (breath-hold induced) signal at 7T. Comparing 1st-2nd with high degree shimming, the Δ|B₀| changes are spatially varying. For activation, the largest regions of increase are in the inferior frontal region; the largest regions of decrease are in the middle temporal lobe. Overall, there is a 4.3% increase in total activated pixels.

- 
- ¹NeuroSpin, CEA, Gif-sur-Yvette, France
- Diffusion fMRI (DfMRI) allows to monitor brain function without BOLD vascular confounding effects. To elucidate the origin of the DfMRI response we performed DfMRI experiments at single neuron and ganglia level upon dopamine stimulation of *Aplysia californica* buccal ganglia using 17.2T MR microscopy. Neural swelling, evidenced from optical microscopy, resulted in an intracellular ADC increase reflecting cytoplasm dilution and an ADC decrease at ganglia level. While the mechanism of this ADC decrease remains putative these results are consistent with the hypothesis that the ADC decrease observed with DfMRI upon neuronal activation at tissue level reflects activation induced cell swelling.

- ¹Center for Neuroscience Imaging Research, Institute for Basic Science (IBS), Suwon, Korea, Republic of, ²Department of Biomedical Engineering, Sungkyunkwan University, Suwon, Korea, Republic of
- In general, gradient-echo (GE) BOLD contains extravascular (EV) contributions from all sized vessels, while spin-echo (SE) BOLD is sensitive to microvessels. Based on simulation, the EV BOLD signal is dependent linearly on B_0 for macrovessels, and quadratically on B_0 for microvessels. Here, we performed GE and SE BOLD fMRI of α -chloralose anesthetized rats responding to forepaw stimulation on an ultrahigh magnetic field of 15.2T. Stimulation-induced R_2 change was quadratically on B_0 , indicating that microvessel contributions are dominant. SE BOLD at ultrahigh fields can detect precise activation sites and can be used for high-resolution fMRI to detect fine functional structures.

- Several strategies have been proposed for maximizing neuronal specificity of fMRI by utilizing pulse sequences that are primarily sensitive to signal changes within microvasculature. Here we compare the microvascular sensitivity of high-resolution balanced SSFP and gradient-echo EPI at 9.4T using cortical depth analyses within human visual cortex. Because of the large draining vessels lying along the pial surface, the behavior of fMRI signals as a function of cortical depth can provide helpful insights into the vascular contributions. Our preliminary analyses suggest that, for the protocols used here, both balanced SSFP and EPI show similar cortical depth profiles of BOLD responses.

- 

¹Radiology Department, Third Affiliated Hospital of Kunming Medical University, Kunming, People's Republic of China, ²Radiology Department, Third Affiliated Hospital of Kunming Medical University, ³Third Affiliated Hospital of Kunming Medical University, ⁴GE healthcare

In this article, to prospectively investigate the changes of quantitative parameters in dynamic contrast-enhanced MRI (DCE-MRI) and the apparent diffusion coefficient (ADC) of diffusion weighted imaging (DWI) in cervical cancer patients before and after neoadjuvant chemotherapy (NACT). It showed that quantitative parameters of DCE-MRI and ADC provided a new noninvasive way to reflect the changes of hemodynamics and water molecular diffusion in cervical cancer patients with NACT.

Characterize the Effect of Regional Variations in Venule Vasculature Related to Temporal Variability of Hemodynamic Responses Latency at the Human Primary Visual Cortex

Yi-Tien Li^{1,2}, Jo-Fu Lotus Lin¹, Pu-Yeh Wu¹, Kevin W.-K. Tsai³, and Fa-Hsuan Lin^{1,4}

¹Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ²Department of Medical Imaging, Taipei Medical University - Shuang Ho Hospital, New Taipei, Taiwan, ³Aim for the Top University Project Office, National Taiwan Normal University, Taipei, Taiwan, ⁴Department of Neuroscience and Biomedical Engineering, Aalto University, Espoo, Finland

We correlated between the temporal characteristics of the BOLD signals and venule structure at human primary visual cortex (V1). Functional MRI was measured by the high temporal resolution (100ms) simultaneous-multi-slice inverse imaging. Venule probability map was estimated from high spatial resolution (0.85mm) susceptibility-weighted imaging (SWI). Significant correlation was found between venule density and intra-/inter-subject temporal variability of the BOLD signal at V1. This correlation suggests that the temporal instability of BOLD signal is likely attributed to vascular structure or reactivity.

Gadoxetic acid-enhanced MR imaging of the liver: the effect on hepatic fat quantification in hepatobiliary phase using mDXION-Quant
shuangshuang xie¹, qing li¹, zhizheng zhao², yue cheng¹, and wen shen¹

¹Tianjin First Center Hospital, Tianjin, People's Republic of China, ²Philips healthcare, Beijing, People's Republic of China

This study evaluated the effect of Gd-EOB-DTPA on fat quantification using a multiecho reconstruction technique with T2* correction. Forty-six patients with suspected hepatic tumors underwent Gd-EOB-DTPA enhanced MR imaging and single breath hold 3D mDXION-Quant for hepatic fat quantification before and 20 minutes after the administration of Gd-EOB-DTPA. Fat fraction (FF) and R2* of the liver parenchyma, spleen parenchyma and vertebral body were measured and compared between pre- and post-contrast. FF measurements of liver, spleen, vertebral body and R2* measurements of liver, spleen revealed no significant difference between the two measurements, and R2* increased in liver and vertebral body significantly after 20 minutes of Gd-EOB-DTPA administration. In addition, good agreement of FF measurement was seen in the Bland-Altman plots. We conclude mDXION-Quant can obtain stable fat quantification in the hepatobiliary phase, without the impact of an increased R2* in liver parenchyma. But R2* maps should be obtained prior to Gd-EOB-DTPA administration.

Relative latency and temporal variability of BOLD fMRI signal in the ventral visual pathway

Jo-Fu Lotus Lin¹, Ying-Hua Chu¹, Yi-Cheng Hsu¹, and Fa-Hsuan Lin^{1,2}

¹Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ²Department of Neuroscience and Biomedical Engineering, Aalto University, Espoo, Finland

We used simultaneous-multi-slice inverse imaging to characterize the relative latency and temporal variability of BOLD signals in the human ventral visual pathway with 0.1 s precision. The intra-subject and inter-subject variability were 0.39 (s) +/- 0.49 (s) and 0.51 (s) +/- 0.77 (s) when images of faces were presented. When scrambled faces were shown, the intra-subject and inter-subject variability were 0.42 (s) +/- 0.46 (s) and 0.56 (s) +/- 0.74 (s). With higher temporal resolutions, we showed temporal variability of HRF vary across cortical areas. Within the same cortical area, the temporal variability of HRF differ between different visual stimulations.

Simultaneous assessment of total CBV, aCBV and BOLD measures at 7 Tesla in motor and somatosensory cortices

Rosa M Sanchez Panchuelo¹, Robert Turner^{1,2,3}, and Susan Francis¹

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom, ²Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ³University of Amsterdam, Amsterdam, Netherlands

We combined Arterial Spin Labelling (ASL) and Vascular Space Occupancy (VASO) techniques into a double acquisition FAIR sequence with double echo readout to provide simultaneous measures of arterial Cerebral Blood Volume (aCBV), total CBV and BOLD signals. Using this technique at 7T, we successfully detected aCBV and total CBV (and BOLD) changes induced by both a motor task and a vibrotactile sensory stimulation paradigm, and show that activation maps derived with the independent ASL and VASO techniques largely overlap.

5261

Computer 35

Functional brain imaging with high spectral and spatial resolution MRI at 3T

Sean Foxley¹, Xiaodong Guo¹, and Gregory S Karczmar¹

¹Radiology, University of Chicago, Chicago, IL, United States

Functional data were acquired of a finger tapping experiment using a conventional EPI approach as well as using high spectral and spatial resolution water spectra acquired using EPSI at 3T. Activation maps of both acquisition strategies were produced and compared. Expected task dependent areas of activation were seen in both, however, activation volumes were smaller in EPSI data. This could indicate that different Fourier components of the water spectrum are differentially affected by the BOLD effect. If this is the case, detailed analyses of the water spectrum could contribute to our understanding of the relationship between cognitive processes and the hemodynamic response.

- T2-weighted fMRI methods including Spin-Echo (SE) and balanced SSFP (bSSFP), became of particular interest to reach superior functional specificity in high field application. However, both techniques suffer from a number of practical limitations. SE fMRI may be SAR limited at high fields. On the other hand, bSSFP suffers from dark bands. To eliminate dark bands in bSSFP, non-balanced-SSFP (nbSSFP) fMRI was previously suggested. Here, we developed a robust version of nbSSFP by using a single SSFP-echo sequence to decrease motion effects. The performance of the suggested sequence is evaluated and the results obtained are compared with bSSFP and SE-EPI fMRI.

- While the existing BOLD signal model often use a single-compartmental, empirical relationship among fMRI response, blood flow and neural metabolic demand, some model parameters can only be determined from calibration challenges. In this study, for the first time, the role of intravascular blood motion on BOLD response is evaluated by Monte-Carlo simulation. Combined with an analytical description of extravascular contribution, a unified BOLD signal model without the need for calibration can be established, enabling the quantification of neurovascular coupling efficiency in both goal directed and spontaneous neuronal activations.

 Cristina Chavarrias¹, Guilherme Blazquez Freches¹, and Noam Shemesh¹
- 
- ¹Champalimaud Neuroscience Programme, Champalimaud Centre for the Unknown, Lisbon, Portugal
- Diffusion fMRI (dfMRI) is highly promising for improving the detection of active regions with higher spatial accuracy, as well as for its potential of resolving faster dynamics than its BOLD counterpart. To test this hypothesis, we compared BOLD and dfMRI in the auditory pathway of the mouse, which exhibits clear tonotopy in electrophysiology. Our findings suggest that dfMRI activation maps are more localized and are in agreement with the expected area of activation in the inferior colliculus; dfMRI signals were also ~3s faster than BOLD signals. These results are expected to enable brainwide characterization of auditory reorganization, function, and plasticity.

- 5267 **Computer 41** **Evaluation of two novel MRI techniques for the assessment of intracranial pulsatility**
 Bowen Fan¹, Lirong Yan², Kay Jann², Mayank Jog², Ying Kui³, and Danny JJ Wang²
- 
- ¹Department of Engineering Physics, Tsinghua University, Beijing, People's Republic of China, ²Laboratory of FMRI Technology, Mark & Mary Stevens Neuroimaging and Informatics Institute, Keck School of Medicine, University of Southern California, University of Southern California, CA, United States, ³Key Laboratory of Particle and Radiation Imaging, Ministry of Education, Medical Physics and Engineering Institute, Department of Engineering Physics, Tsinghua University, Beijing, People's Republic of China

The brain pulsatility plays an important role in various cerebral pathology, such as brain tumor and traumatic brain injury. Two MRI methods have been recently developed for assessing brain biomechanical features using a ECG-gated cine sequence with different processing strategies. In this study, we evaluated and compared the two methods. Consistent findings were obtained using both methods that the majority of cardiac-induced brain pulsatile motion occurs in the brain stem and basal ganglia as well as in big arteries.

Bayesian Inference of Brain Oxygenation and Deoxygenated Blood Volume in Acute Stroke using Streamlined Quantitative BOLD
Matthew T Cherukara¹, Alan J Stone², Davide Carone³, Radim Licenik³, George WJ Harston³, James Kennedy³, Michael A Chappell¹, and Nicholas P Blockley²

¹Institute of Biomedical Engineering, Department of Engineering Science, University of Oxford, Oxford, United Kingdom, ²FMRIB Centre, Nuffield Department of Clinical Neuroscience, University of Oxford, Oxford, United Kingdom, ³Acute Stroke Programme, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom

Streamlined Quantitative-BOLD provides a method for quantifying brain oxygen metabolism, in particular, deoxygenated blood volume and oxygen extraction fraction, based on linear fitting of values obtained from an asymmetric spin-echo sequence. It is possible that a curve-fitting approach may yield more robust values for these parameters. This study investigated the feasibility of estimating brain metabolic and vascular parameters through a Bayesian framework, through simulations, and analysis of patient data. It was found that under the current model, simultaneous estimation of oxygen extraction fraction and blood volume was not reliable, suggesting a limit to the model or acquisition protocol.

The neurovascular fingerprint of BOLD bSSFP: the impact of vessel size, orientation and intravascular contribution
Klaus Scheffler^{1,2}, David Kleinfeld^{3,4}, Philbert Tsai³, Mario Báez-Yáñez¹, and Philipp Ehses¹

¹MPI biol Cybernetics, Tübingen, Germany, ²Department of Biomedical Magnetic Resonance, University of Tübingen, Tübingen, Germany, ³Department of Physics, University of California at San Diego, San Diego, CA, ⁴Section of Neurobiology, University of California, La Jolla, CA

The neurovascular fingerprint of BOLD (blood oxygen level dependent) bSSFP (balanced steady-state free precession) is analyzed by Monte Carlo simulations for different vessel geometries and on a vectorized vessel data set of mouse parietal cortex. The results support that bSSFP yields vascular properties similar to those found with spin echo BOLD, a small intravascular signal contribution except for larger vessels, and a high selectivity to microvessels.

5272

Computer 46

Which fMRI contrast is most specific for high resolution layer-dependent fMRI? Comparison study of GE-BOLD, SE-BOLD, T2-prep BOLD and blood volume fMRI?

Laurentius Huber¹, Jun Hua², Valentin G Kemper³, Sean Marrett⁴, Benedikt A Poser³, and Peter A Bandettini¹

¹SFIM, NIMH, Bethesda, MD, United States, ²FM Kirby Research Center, Johns Hopkins, United States, ³MBIC, Maastricht University, Netherlands, ⁴NIMH, United States

fMRI at ultra-high field strengths ($\geq 7T$) allow submillimeter voxels across different cortical layers. A big challenge to infer layer-dependent activity information, however, is to find an fMRI contrast that has the best combination of local specificity to microvascular responses within cortical layers and sensitivity to detect activity changes. Here we compare contrast mechanisms that have been proposed to be applicable to layer-dependent fMRI, including blood volume fMRI with VASO, SE-BOLD, T2/T1 ρ -prep-BOLD, diffusion weighted T2-prep-BOLD. We find that CBV-weighted VASO and T2-prep methods have a favorable compromise between sensitivity and specificity. Hence, we believe that these fMRI methods might be better suited for layer-dependent applications than conventionally used GE-BOLD and SE-EPI.

5273

Computer 47

Comparison of BOLD and CBV impulse-response to visual stimulation in humans in the presence of Ferumoxytol
Jacco A de Zwart¹, Peter van Gelderen¹, Matthew Schindler², Pascal Sati², Jiaen Liu¹, Daniel S Reich², and Jeff H Duyn¹

¹Advanced MRI section, LFMI, NINDS, National Institutes of Health, Bethesda, MD, United States, ²Translational Neuroradiology section, NINDS, National Institutes of Health, Bethesda, MD, United States

Ferumoxytol is a blood-pool-bound superparamagnetic iron-oxide particle (SPIO) that has been shown to yield CBV-dominated fMRI contrast in humans. Differences in impulse-response (IR) timing were previously demonstrated in animals when comparing SPIO-fMRI to BOLD-fMRI. Since BOLD IR is known to differ between humans and animals, we aimed to repeat this SPIO-fMRI to BOLD-fMRI comparison in humans. SPIO-fMRI was performed in human visual cortex and IR was compared to BOLD data from the same subjects. Shorter stimulus onset time and time-to-peak were found. Stimulus design minimized neuronal interaction effects between stimuli; residual inter-stimulus interaction effects, presumably vascular in origin, were found to be minor in SPIO-fMRI, on the same scale as in BOLD.

Computer 48

THE IMPACT OF THE LOCAL, MESOSCOPIC FREQUENCY DISTRIBUTION AND DIFFUSION IN GRAY AND WHITE MATTER TO THE STATIC bSSFP SIGNAL PROFILE

Mario Gilberto Báez-Yáñez^{1,2}, Philipp Ehses^{1,3}, and Klaus Scheffler^{1,3}

¹Department of High-Field Magnetic Resonance, Max Planck Institute for Biological Cybernetics, Tuebingen, Germany, ²Graduate Training Centre of Neuroscience, University of Tuebingen, Tuebingen, Germany, ³Department of Biomedical Magnetic Resonance, University of Tuebingen, Germany

The phase accumulation that spins experience during a MR sequence is closely linked to the microstructure within the voxel, and basically produces changes in T_2^* or T_2 . The present abstract demonstrates how the static bSSFP signal profile is modified by the influence of local susceptibility differences produce by the underlying local-frequency distribution and diffusion effects related to white matter and gray matter at 9.4T. We apply an analytical presentation of the diffusion-modified frequency distribution, previously only used for gradient and spin echoes, to bSSFP and we prove the applicability of this theory to bSSFP by Monte Carlo simulations and measurements.

Dynamic Changes of Functional Connectivity within and between Resting State Networks in Intractable Mesial Temporal Lobe Epilepsy

Chao Zhang¹, Kuncheng Li¹, Nan Chen¹, and Hongyu Yang¹

¹Xuanwu Hospital, Capital Medical University, Beijing, People's Republic of China

This study aimed to observe dynamic functional organization changes of large-scale resting state network (RSN) in MTLE and the patient who got seizure free after surgical treatment. Subject specific RSNs of three groups (healthy controls, presurgical group and posttreatment group) were extracted using group-information guided independent component analysis. Then, we calculated and compared the FC results between three groups, and we found FC altered markedly before and after surgical treatment. In addition, there was no statistical difference between posttreatment group and healthy controls. Our results may provide valuable information for further understanding of the pathophysiological mechanisms of intractable MTLE.

5276

Computer 50

Topologically Reorganized Functional Connectivity in Children with Abacus Training

Ye Xie¹, Jian Weng¹, Chunjie Wang¹, and Feiyan Chen¹

¹Bio-X Laboratory, Department of Physics, Zhejiang University, Hangzhou, People's Republic of China

Cognitive training is an interesting topic in Neuroscience. Abacus-mental based calculation (AMC) training improves math ability that indicates it might affect functional connectivity architecture. Modularity analysis showed between-group differences in visual network and cingulo-opercular network (CON). Compared to the controls, increased local efficient observed in visual network, while decreased in CON in AMC experts. An alternative reason is that visual-spatial strategy involving in AMC training rather than languish strategy, leading to different trend to networks related to different function. Our findings shed light on topological reorganization of functional connectivity induced by AMC training.

Increased resting-state functional connectivity within subgenual anterior cingulate cortex network reveals the neural substrate of emotion regulation following mindfulness-based stress reduction (MBSR) training

Yao-Chia Shih^{1,2}, Chang-Le Chen^{2,3}, Shih-Chin Fang⁴, Tzung-Kuen Wen⁵, Da-Lun Tang⁶, Si-Chen Lee⁷, and Wen-Yih Isaac Tseng^{2,3,8}

¹Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ²Institute of Medical Device and Imaging, National Taiwan University College of Medicine, Taipei, Taiwan, ³Graduate Institute of Brain and Mind Sciences, National Taiwan University College of Medicine, Taipei, Taiwan, ⁴Department of Neurology, Cardinal Tien Hospital Yonghe Branch, New Taipei City, Taiwan, ⁵Department of Buddhist Studies, Dharma Drum Institute of Liberal Arts, New Taipei City, Taiwan, ⁶Department of Mass Communication, Tamkang University, Taipei, Taiwan, ⁷Department of Electrical Engineering, National Taiwan University, Taipei, Taiwan, ⁸Molecular Imaging Center, National Taiwan University, Taipei, Taiwan

Mindfulness-based stress reduction (MBSR) has been known to improve emotion regulation and cure mood disorders. The present longitudinal study aimed to clarify the effects of MBSR training and practice on the neural substrates of emotion regulation. Resting-state functional MRI (rsfMRI) exams were performed at three time points to investigate changes of functional connectivity (FC) within the subgenual anterior cingulate cortex (sgACC) network. MBSR training and practice strengthened the FC of sgACC with the inferior frontal gyrus and with the insula, and reduced the level of anxiety and depression. The findings reveal the neural substrates of emotion regulation process following MBSR.

Tinnitus distress is linked to enhanced resting-state functional connectivity from the limbic system to the auditory cortex

Yu-Chen Chen¹, Wenqing Xia², and Xindao Yin¹

¹Department of Radiology, Nanjing First Hospital, Nanjing Medical University, Nanjing, China, Nanjing, People's Republic of China, ²Nanjing First Hospital, Nanjing Medical University, Nanjing, China, Nanjing, People's Republic of China

Our results identified disrupted effective connectivity networks in the limbic regions of tinnitus patients. Tinnitus severity was positively correlated with a bilateral increase in effective connectivity from the amygdala to the auditory cortex on the same side. In addition, tinnitus duration was positively correlated with enhanced effective connectivity from the right hippocampus to the left auditory cortex. These findings mainly emphasized the crucial role of limbic system and limbic-auditory interaction in tinnitus patients, which could help enhance our understanding of the neuropathological mechanisms underlying tinnitus.

Accelerated intermittent theta burst stimulation, applied to the left DLPFC, influences dynamics in depression related networks

Debby Klooster^{1,2,3}, Rene Besseling^{1,2,3}, Suzanne Franklin¹, Antoine Bernas¹, Romain Duprat², Albert Aldenkamp^{1,2,3}, and Chris Baeken²

¹Eindhoven University of Technology, Eindhoven, Netherlands, ²University Hospital Ghent, Ghent, Belgium, ³Academic Center for epileptology Kempenhaeghe, Heeze, Netherlands

The effect of accelerated intermittent theta burst stimulation (aiTBS) is investigated in three resting-state networks involved in depression: default mode network (DMN), central executive network (CEN), and salience network (SN). Multivariate Granger causality analysis was performed between time-series representing each network and between time-series of nodes belonging to these networks. The effects of the latter analysis were quantified by the in- and out-degree. No between-network effects were found but specific connections showed increased or decreased Granger causality after stimulation. Clinical responders showed changes in the in- and out-degree of the anterior cingulate, known to be important in depression pathology.

Abnormal Heschl's gyrus resting-state functional connectivity in patients with presbycusis

Fei Gao¹, Guangbin Wang¹, Bin Zhao¹, Fuxin Ren¹, and Weibo Chen²

¹Shandong Medical Imaging Research Institute, Shandong University, Jinan, People's Republic of China, ²Philips Healthcare, Shanghai, People's Republic of China

This study revealed abnormal resting-state functional connectivity between the Heschl's gyrus and distributed regions located in the hearing-related and language-related areas in patients with presbycusis. Our findings could be important for exploring imaging evidence of central component of presbycusis.

5284

Computer 58

The Synchronization of Brain Activity in Real-Time Human Interaction Revealed by fMRI Hyperscanning

Jacky Tai-Yu Lu¹, Claire Hui-Chuan Chang², Shu-Yu Huang¹, Wen-Jui Kuo³, and Fa-Hsuan Lin^{4,5}

¹Graduate Institute of Biomedical Electronics and Bioinformatics, National Taiwan University, Taipei, Taiwan, ²College of Humanities and Social Sciences, Taipei Medical University, Taipei, Taiwan, ³Institute of Neuroscience, National Yang-Ming University, Taipei, Taiwan, ⁴Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ⁵Department of Neuroscience and Biomedical Engineering, Aalto University, Espoo, Finland

This study used functional magnetic resonance imaging (fMRI) hyperscanning to estimate the synchronization of human brain activations in interpersonal interaction by inter-subject correlation (ISC) analysis. Brain activations of pairs of subjects were recorded simultaneously during real-time video tennis game under cooperation, competition, and a control condition involving no interaction. Compared to control condition, higher ISC was found in premotor area (BA6) and right precuneus in the two game conditions. The finding of premotor area suggests that mutual action understanding was supported by the mirror neuron system during interpersonal interaction.

5285

Computer 59

Sense of agency is a biological function sustained by a somatosensory-premotor network

Tommaso Gili^{1,2}, Valentina Ciullo^{2,3}, Daniela Vecchio^{2,3}, Gianfranco Spalletta^{2,4}, and Federica Piras²

¹Enrico Fermi Center, Rome, Italy, ²Neuropsychiatry Laboratory, IRCCS Santa Lucia Foundation, Rome, Italy, ³Psychology Department, Sapienza University, Rome, Italy, ⁴Menninger Department of Psychiatry and Behavioral Sciences, Baylor College of Medicine, Houston, TX, United States

Sense of agency (SoA) refers to the experience of controlling one's own actions. Temporal distortions between the action and the effect mislead agency attribution. We investigated the covariance between the amount of functional interactions among brain regions at rest and SoA. We found that the functional network involved in self-agency attribution included the premotor and somatosensory cortices bilaterally, and the right superior parietal lobule. This provides the first evidence that functional connectivity at rest in healthy subjects varies along with experienced SoA, implying that self-agency is processed within an intrinsic brain functional module.

5286

Computer 60

Organization and hierarchy of the human brain functional network at rest lead to a chain-like core.

The intrinsic functional architecture of the brain and its alterations due to cognitive engagement, ageing and diseases are nodal topics in neuroscience, attracting considerable attention from many disciplines of scientific investigation. Complex network theory offers powerful tools to investigate brain connectivity disclosing the structure of the human brain functional network. Here we put forward a number of methods to investigate the network of brain areas coupled by their functional coordination without introducing exogenous thresholds. In this way we overcame the problem of having a fully connected network and found the intrinsic structure of the functional architecture of the brain.

Oxytocin influences the directed connectivity between the precuneus and the dorsolateral prefrontal cortex

Jyothika Kumar¹, Sarina J Iwabuchi², Birgit A Völlm¹, and Lena Palaniyappan³

¹Division of Psychiatry and Applied Psychology, University of Nottingham, Nottingham, United Kingdom, ²Radiological Sciences, Division of Clinical Neuroscience, University of Nottingham, Nottingham, United Kingdom, ³Department of Psychiatry & Robarts Research Institute, University of Western Ontario, London, ON, Canada

The default mode network (DMN) is now known to play an important role in social cognition. Thus, we hypothesized that the social neuropeptide oxytocin (OXT) will modulate the connectivity of the DMN. We used Granger Causality Analysis and found that intranasal OXT modulates the effective or 'causal' connectivity between the precuneus: a key DMN node and the dorsolateral prefrontal cortex, a key region in the central executive network. Thus, OXT has the potential to enhance the cooperative role of the DMN, which could explain the mechanistic action by which OXT improves social cognition in disorders such as autism and schizophrenia.

Computer 62

Identify the neural basis of vascular dynamic network connectivity with high-field fMRI

Yi He^{1,2}, Maosen Wang^{1,2}, Xuming Chen^{1,2}, and Xin Yu¹

¹High-field Magnetic Resonance, Max Planck Institute for Biological Cybernetics, Tuebingen, Germany, ²Graduate Training Centre of Neuroscience, International Max Planck Research School, University of Tuebingen, Tuebingen, Germany

The vascular dynamic network connectivity was detected with the resting-state fMRI in rodent and human brains (abstract: 3115). However, the basis of vascular dynamic connectivity is unclear. Here, the GCaMP6-mediated calcium signal simultaneously detected by fiber optics with fMRI showed slow-frequency fluctuation (0.01-0.04Hz) correlated to the single-vessel fMRI signal fluctuation with lead times from 1 to 5 seconds. In addition, the correlation was observed on the slow-frequency oscillation of the power profile of the spontaneous calcium burst spikes with frequency bandwidth of 1-10Hz. Thus, the vascular dynamic network connectivity demonstrates the hemodynamic state changes coupled to the brain state fluctuation.

Individualized Functional Parcellation of Human Amygdala using a Semi-Supervised Clustering Method based on 7T Resting State fMRI Data
Xianchang Zhang^{1,2}, Hewei Cheng³, Zhentao Zuo¹, Ke Zhou¹, Bo Wang¹, Lin Chen^{1,2}, Yong Fan⁴, and Rong Xue^{1,2,5}

¹State Key Laboratory of Brain and Cognitive Science, Beijing MR Center for Brain Research, Institute of Biophysics, Chinese Academy of Sciences, Beijing, People's Republic of China, ²University of Chinese Academy of Sciences, Beijing, People's Republic of China, ³Department of Biomedical Engineering, School of Bioinformatics, Chongqing University of Posts and Telecommunications, Chongqing, People's Republic of China, ⁴Department of Radiology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States, ⁵Beijing Institute for Brain Disorders, Beijing, People's Republic of China

Functional subspecialization of human amygdala has been revealed in a variety of studies based on histological, in-vivo imaging, and meta-data. However, most of the existing studies identified functional subregions of amygdala at a group level. In this study, we investigated individualized functional neuroanatomy of amygdala based on 7T resting-state fMRI data with high spatiotemporal resolution. Our results have demonstrated that an improved semi-supervised clustering algorithm successfully parcellated individual subjects' amygdala into 3 subregions, each of them having distinctive functional connectivity patterns. The individualized functional subregions of amygdala may better capture individual variability in functional neuroanatomy than their group level counterparts.

Contrary Effect of Stressful vs. Non-stressful Striped Patterns on Human Visual Cortical Functional Connectivity

Jie Huang¹ and David C. Zhu^{1,2}

¹Department of Radiology, Michigan State University, East Lansing, MI, United States, ²Department of Psychology, Michigan State University, East Lansing, MI

Areas across the visual cortex are functionally connected. A stressful striped pattern induces perceptual illusions/distortions and visual discomfort in most people, headaches in patients with migraine, and seizures in patients with photosensitive epilepsy. In contrary, a non-stressful striped pattern does not induce such effects. This study found that a 25-min visual stimulation showed a significantly contrary effect of the stressful vs. non-stressful striped patterns on human visual cortical functional connectivity (FC). To the contrary of the strengthening effect of the stressful striped pattern on the FC, the non-stressful striped pattern showed a weakening effect on the FC.

Impact of previous episodes of hepatic encephalopathy on post-transplantation brain function recovery

Yue Cheng¹ and Wen Shen²

¹Tianjin First Central Hospital, Tianjin, People's Republic of China, ²Tianjin First Central Hospital, People's Republic of China

Purpose: To investigate the impact of prior episodes of hepatic encephalopathy (HE) on post-transplantation brain function recovery. **Method:** Thirty-three cirrhotic patients (HE, n=15 and noHE, n=18) and 30 healthy controls were included. Functional connectivity strength (FCS) were compared between the pre-LT data and the post-LT data, respectively. **Results:** For the noHE group, the altered FCS found pre-LT largely returned to nearly normal levels soon after LT. The abnormal FCS prior to LT was largely preserved in the HE group, including high-level cognition-related and vision-related areas. **Conclusion:** Pre-LT episode of HE may have adverse effects on post-LT brain function recovery.

Computer 66

Effects of motor dysfunction on functional connectivity and network topology in Parkinson's disease

Karthik Sreenivasan¹, Virendra Mishra¹, Zhengshi Yang¹, Xiaowei Zhuang¹, Sarah Banks¹, Dietmar Cordes^{1,2}, and Ryan R Walsh¹

¹Cleveland Clinic Lou Ruvo Center for Brain Health, Las Vegas, NV, United States, ²University of Colorado Boulder, Boulder, CO, United States

The objective of this study was to use resting-state functional connectivity and graph theory to determine how the topology of the network is altered in PD with respect to severity of motor dysfunction. The current study revealed altered functional connectivity and topological properties of networks in PD with respect to severity of motor dysfunction. Our results point to a shift towards a less efficient network topology with altered integration and segregation in more motorically affected patients.

5293

Computer 67

Differential changes in functional connectivity of fronto-striatal and motor-striatal circuits in early and premanifest Huntington's Disease measured by ultra-high field (7T) resting state BOLD fMRI

Jun Hua^{1,2}, Martin Kronenburger^{3,4}, Xinyuan Miao^{1,2}, James Pekar^{1,2}, Peter van Zijl^{1,2}, and Christopher Ross^{3,4,5}

¹Dept. of Radiology, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²F.M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD, United States, ³Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ⁴Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ⁵Department of Neuroscience and Pharmacology, Johns Hopkins University School of Medicine, Baltimore, MD, United States

Huntington's disease (HD) is a neurodegenerative disorder characterized by motor, cognitive and behavioral deficits. The striatum is one of the first brain regions that show detectable atrophy in HD. Reduced functional connectivity between striatum and motor cortex has been reported. Here, we report decreased motor-striatal connectivity but increased **fronto-striatal** connectivity in early/premanifest HD patients. We speculate that this may imply a compensatory mechanism, where additional cortical regions are recruited to subserve functions that have been impaired due to HD pathology. We also found strong correlations between functional connectivity and genetic measures, suggesting its potential value as a biomarker for HD.

Computer 68

Subthalamic nucleus activation under audio-motor transformation in lateralized Parkinson's disease

Oleksii Omelchenko¹, Zinayida Rozhkova², Irina Karaban³, and Mykola Makarchuk⁴

¹Human and Animal Physiology, Taras Shevchenko National University of Kyiv, Kyiv, Ukraine, ²Medical Clinic BORIS, Kyiv, Ukraine, ³Department of extrapyramidal disorders, D. F. Chebotarev Institute of Herontology, Kyiv, Ukraine, ⁴Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

We hypothesized that audio-motor transformation (AMT) play an important role in voice-guided movement initiation with STN involvement. We propose AMT-related subthalamic nucleus activation analysis in lateralized PD for tremor asymmetry influence study. We identified PD symptoms laterality dependent STN activation peculiarities. Obligatory left STN activation in AMT supposes its role in motor command switching. Bilateral STN activation during the movement execution supports its proposed role as a motor error correction node.

Distributed and overlapping cortical networks represent visual categories

Haiguang Wen¹, Junxing Shi¹, Kuan Han¹, and Zhongming Liu²

¹Electrical and Computer Engineering, Purdue University, West Lafayette, IN, United States, ²Electrical and Computer Engineering and Biomedical Engineering, Purdue University, West Lafayette, IN, United States

The principle of cortical representations when thousands of real-life objects and categories are involved remains unclear. Here, we built a computational model of the human visual system by using a deep neural network and predicted the cortical responses to natural visual stimuli. In particular, we trained the model by using fMRI data obtained while subjects watched very long (>10 hours) natural movie stimuli that contained thousands of visual object categories. Based on the model, we systematically analyzed the activation patterns in the brain induced by different kinds of object categories. We found that the categorical information was represented by distributed and overlapping cortical networks, as opposed to discrete and distinct areas. Three cortical networks represented such broad categories as biological objects, non-biological objects, and background scenes. More fine-grained categorical representations in the brain suggest that visual objects share more (spatially) similar cortical representations if they share more similar semantic meanings.

Modulation of Expectation on Sound-to-Meaning Mapping during Speech Processing: An fMRI Study

Bingjiang Lyu^{1,2,3}, Jianqiao Ge^{1,2,3}, Zhendong Niu⁴, Li Hai Tan⁵, Tianyi Qian⁶, and Jia-Hong Gao^{1,2,3}

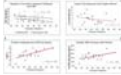

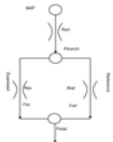

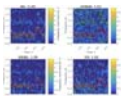

¹Center for MRI Research, Peking University, Beijing, People's Republic of China, ²McGovern Institute for Brain Research, Peking University, Beijing, People's Republic of China, ³Beijing City Key Lab for Medical Physics and Engineering, Peking University, Beijing, People's Republic of China, ⁴School of Computer Science and Technology, Beijing Institute of Technology, Beijing, People's Republic of China, ⁵Center for Language and Brain, Shenzhen Institute of Neuroscience, Shenzhen, People's Republic of China, ⁶MR Collaborations NE Asia, Siemens Healthcare, Beijing, People's Republic of China

Spoken language comprehension relies on both the identification of individual words and the expectations arising from contextual information. A distributed fronto-temporal network is known to facilitate the mapping of speech sounds onto corresponding meanings. However, how prior expectations influence this efficient mapping at the neuroanatomical level, especially for individual words, remains unclear. Using functional magnetic resonance imaging, we addressed this question in the framework of the dual-stream model by investigating both the neural substrates and their mutual functional and effective connectivity. Our results revealed how this ubiquitous sound-to-meaning mapping in daily communication is achieved in a predictive manner.

- 5299 **Computer 73** **Lower Resting Cerebral Blood Flow but Greater Cerebrovascular Reactivity in Young Adults with Higher Aerobic Fitness**
Catherine Foster¹, Jessica J Steventon^{1,2}, Daniel Helme¹, Valentina Tomassini³, and Richard G Wise¹
- 
- ¹*School of Psychology, Cardiff University Brain Research Imaging Centre, Cardiff, United Kingdom,* ²*School of Medicine, National Mental Health Research Institute, Cardiff, United Kingdom,* ³*School of Medicine, Institute of Psychological Medicine and Clinical Neurosciences, Cardiff, United Kingdom*
- We measured the association between aerobic fitness and cerebral blood flow (CBF) and cerebrovascular reactivity (CVR) in young, healthy adults using multiple inversion time (MTI) arterial spin labelling (ASL), with a hypercapnic challenge to assess CVR. The results show that higher fitness is associated with lower baseline CBF and greater CVR. Although studies with a larger sample size are required to clarify the relationship between fitness and cerebrovascular function in early adulthood, the current results suggest that aerobic fitness may promote vascular efficiency and reserve.

- We analyze the structure of physiological noise in the \$\$\$\$-space of BOLD fMRI. We use DRIFTER which is an algorithm based on optimal Bayesian smoothing techniques for separation of the fMRI signal to a BOLD signal component and physiological noises. DRIFTER is run independently for each spatial frequency and it is shown that the physiological noise lies in the \$\$\$\$-space points with low spatial frequency and that its amplitude is proportional to the BOLD signal. This result suggests that we can lower the computational burden without losing estimation accuracy by running DRIFTER only on a subset of \$\$\$\$-space points.

- 
- ¹*Anaesthesia, University of Toronto, Toronto, ON, Canada*
- Conventional measurements of cerebrovascular reactivity (CVR) are often based on the BOLD changes in response to a ramp CO₂ stimulus ranging from hypo- to hypercapnia. Using a simple model of two vascular beds, one with a healthy standard reference resistance, competing for the same limited blood supply, we derive the sigmoidal relative resistance changes in the other branch of the model from measured BOLD responses. Maps displaying the spatial pattern of the relative resistance sigmoid parameters describe the physiology and pathophysiology of the vessels themselves and thus may provide more clinically useful insight.
-
- 5302 **Computer 76** **Retrospective Independent Component Estimation of Respiratory and Cardiac Artefact Residuals (RICERCAR) in BOLD-fMRI.**
Michael Hütel¹, Andrew Melbourne¹, Dave Thomas¹, Jonathan Rohrer¹, and Sebastien Ourselin¹
- 
- ¹*UCL, London, United Kingdom*
- Variations in the heart and respiration rate have an impact on BOLD-fMRI signal variations. The cardiac cycle causes a pulsatile arterial blood flow which causes slice-specific signal changes resulting in artificial correlations between voxels within the same slice. The introduction of multi-band (MB) EPI acquisitions such as in the Human Connectome Project (HCP) increase such artificial correlations because many slices are acquired at the same slice time. We find physiological-related spatial Independent Components (ICs) and remove their corresponding time courses from BOLD-fMRI scans. Our method RICERCAR outperforms RETROICOR as well as FIX.
-
- 5303 **Computer 77** **The effect of low-level carbon monoxide exposure on BOLD FMRI**
Caroline R Bendell¹, Shakeeb H Moosavi¹, and Mari Herigstad^{1,2}
- 
- ¹*Biological and Medical Sciences, Oxford Brookes University, Oxford, United Kingdom,* ²*Academic Unit of Radiology, University of Sheffield, Sheffield, United Kingdom*
- Carbon monoxide (CO) is a cerebral vasodilator, yet effects of low-level CO exposure (from e.g. smoking) on BOLD FMRI remain unknown. We scanned 12 never-smokers at 3T before and after inhaling low-level CO (or air as a control). CO significantly reduced BOLD response to carbon dioxide during breath holds and attenuated visual cortex activation during visual stimulation and fingertapping, but also increased premotor cortex activation during fingertapping. This indicates that CO generally dampens BOLD signal (possibly through elevated baseline CBF), but that the effect may be task- and/or region-dependent. Caution should be exercised when comparing populations with different CO levels.
-
- 5304 **Computer 78** **Effects of anesthesia on BOLD, electrophysiology, and PO2 signals in the whisker barrel cortex**
Daniil P Aksenov¹, Limin Li¹, Michael Miller¹, Robert Linsenmeier², and Alice M Wyrwicz¹
- ¹*NorthShore University HealthSystem, Evanston, IL, United States,* ²*Northwestern University, Evanston, IL, United States*

A comprehensive understanding of the relationship between neuronal activity and oxygen dynamics in the brain is vital for the accurate interpretation of fMRI results. This study investigates the relationship between changes in blood and tissue oxygen as well as neuronal activity in the awake and anesthetized states. We compare BOLD, PO_2 and electrophysiological signals in the barrel cortex during whisker stimulation in awake and isoflurane-anesthetized rabbits. Our findings suggest that the relationship between BOLD, PO_2 and electrophysiological responses is considerably different in the awake and anesthetized states.

Quantitative Mapping of Cerebrovascular Reactivity using Resting-state BOLD fMRI: A Validation in Healthy Adults

Ali Golestani¹, Luxi Wei², and Jean Chen^{2,3}

¹Department of Psychology, University of Toronto, Toronto, ON, Canada, ²Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada, ³Rotman Research Institute at Baycrest, Toronto, ON, Canada

Cerebrovascular reactivity (CVR) is commonly mapped as the response of the blood oxygenation level dependent (BOLD) signal to a hyper/hypocapnic breathing challenge, which might be intolerable for some patients. We proposed a method to estimate quantitative CVR using intrinsic fluctuations of end-tidal CO_2 (PETCO₂) during resting-state fMRI data acquisition (rs-qCVR). We validated our rs-qCVR method against the "gold-standard" hyper/hypocapnic CVR method, demonstrating significantly association between the two in the majority of the healthy subjects.

Computer 80

Comparison of Quantitative Specific Ventilation Imaging in the Lung with Oxygen Enhanced ¹H and Hyperpolarized ³He Multibreath MRI

Tatsuya J Arai^{1,2,3}, Felix C Horn², Rui Carlos Sá³, Madhwesha R Rao², Guilhem Collier², Rebecca J Theilmann³, G. Kim Prisk³, and Jim M Wild²

¹UT Southwestern Medical Center, Dallas, TX, United States, ²Academic Unit of Radiology, The University of Sheffield, Sheffield, United Kingdom, ³Pulmonary Imaging Laboratory, University of California, San Diego, San Diego, CA, United States

Two multi-breath imaging techniques for quantifying specific ventilation based on oxygen enhanced ¹H and hyperpolarized ³He gas MRI were cross-validated with spatially matched data from the same subjects. With a custom RF torso ¹H array configured with ³He T-R coil in situ we were able to separately acquire ¹H and hyperpolarized ³He MRI during a single scanning session without repositioning the subject. The preliminary study demonstrated qualitative as well as quantitative similarities between the two techniques.

5307

Computer 81

Quantification of Neural Energetic Changes during Visuomotor Learning using Arterial Spin Labelling fMRI

Catherine Foster¹, Jessica Steventon^{1,2}, Ian Driver¹, Daniel Helme¹, Valentina Tomassini³, and Richard G Wise¹

¹School of Psychology, Cardiff University Brain Research Imaging Centre, Cardiff, United Kingdom, ²School of Medicine, Neuroscience and Mental Health Research Institute, Cardiff, United Kingdom, ³School of Medicine, Institute of Psychological Medicine and Clinical Neurosciences, Cardiff, United Kingdom

Recovery of motor function following neurological damage is dependent on functional neuroplasticity. Mechanisms of adaptive plasticity are not well understood, thus limiting the ability to predict recovery following rehabilitation. This study examined the suitability of calibrated fMRI to study cerebrovascular changes during motor learning, as cerebrovascular function plays an important role in neuroplasticity. Results showed cerebral blood flow, BOLD and oxygen metabolism increases from rest with task but decreases with task-learning. However, high inter-subject response variability was observed. Calibrated fMRI shows promise for studying cerebrovascular changes during learning but the repeatability and stability of measurements requires further investigation.

5308

Computer 82

Impact of Physiological Noise on Serial Correlations in Fast Simultaneous Multislice (SMS) EPI at 7T

Saskia Bollmann¹, Alexander Puckett², Ross Cunningham², and Markus Barth¹

¹Centre for Advanced Imaging, The University of Queensland, Brisbane, Australia, ²Queensland Brain Institute, The University of Queensland, Brisbane, Australia

We investigated the influence of physiological noise on statistical inference in fMRI at the single-subject level. By comparing two SMS sequences with a short and a long TR, we explored the interaction between repetition time, physiological noise modelling and the autoregressive model used to characterize serial correlations in fMRI data. Using variational Bayesian inference, we found that fMRI acquisitions with a short TR require accurate modelling of cardiac and respiratory processes to successfully remove serial correlations from the fMRI time series. For the SMS sequence with a longer TR, the standard AR model of order 1 proved sufficient.

5309

Computer 83

Comparison of BH CVR and resting state fMRI to "gold standard" task-based fMRI for assessment of brain tumor-induced neurovascular uncoupling

Shruti Agarwal¹, Haris I. Sair¹, Sachin Gujar¹, Arvind P. Pathak^{1,2}, and Jay J. Pillai¹

¹Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²Dept. of Biomedical Engineering, Johns Hopkins University School of Medicine, Baltimore, MD, United States

Neurovascular Uncoupling (NVU) can critically limit presurgical mapping using blood oxygen level dependent functional magnetic resonance imaging (BOLD fMRI). False-negative activations caused by NVU can lead to erroneous interpretation of clinical fMRI examinations. Brain tumor-related NVU has been previously demonstrated on task-based BOLD fMRI (tbfMRI) and resting state BOLD fMRI (rsfMRI). The purpose of this study is to demonstrate that NVU in the sensorimotor network can be similarly detected on rsfMRI and BH CVR maps as evident in the criterion standard tbfMRI.

¹Laboratory of Biomedical Imaging and Signal Processing, The University of Hong Kong, Hong Kong, Hong Kong, ²Department of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, Hong Kong, ³Department of Electrical and Electronic Engineering, Southern University of Science and Technology, Shenzhen, People's Republic of China, ⁴Department of Physics and Materials Science, City University of Hong Kong, Hong Kong, Hong Kong

The hippocampus is associated with the memory and learning, meanwhile, receives signal from all sensory system indirectly. However, whether and how the hippocampus influences sound processing in the auditory system remains unclear. Our recent study showed that optogenetic stimulation of hippocampus enhances the brain bilateral auditory cortex connectivity. This fMRI study investigated the influence of hippocampus on auditory processing in the inferior colliculus (IC) by using tetrodotoxin (TTX) to pharmacologically deactivate the dorsal hippocampus. For the first time, our results revealed that the dorsal hippocampus plays a dynamic role in shaping the IC auditory response.

Cerebral oxygen extraction fraction measurement using an asymmetric spin echo EPI approach

Yong Zhang¹, Zhongping Zhang¹, Kang Wang², and Zhenyu Zhou¹

¹MR Research China, GE Healthcare, Shanghai, People's Republic of China, ²GE Healthcare, Milwaukee, WI, United States

Quantitative measurement of oxygen delivery and consumption in the brain can provide insight into neurovascular and metabolic coupling. A single shot asymmetric spin echo (ASE) EPI sequence was implemented for quantitative oxygen extraction fraction (OEF) measurement in healthy volunteers for the feasibility study. OEF results were in good agreement with the normal range of 30%-40% reported in the previous literature. ASE EPI shows the potential to provide quantitative OEF maps with good brain coverage and without the need of gas challenges. Further investigation is required to evaluate the sensitivity of OEF measurement in the disease situation, such as stroke.

5312

Computer 86

Eigenvector Centrality Mapping in Detecting Parkinson's Disease

Zhengshi Yang¹, Ryan Walsh¹, Virendra Mishra¹, Karthik Sreenivasan¹, Xiaowei Zhuang¹, Sarah Banks¹, and Dietmar Cordes^{1,2}

¹Cleveland Clinic Lou Ruvo Center for Brain Health, LAS VEGAS, NV, United States, ²University of Colorado Boulder, CO, United States

Eigenvector centrality (EC) is a parameter-free method to measure the centrality of complex brain network structures without a priori assumption. It is here applied to resting state fMRI data acquired from normal controls (NC) and Parkinson's disease (PD) subjects for the purpose of detecting centrality abnormality in PD, a disease known to impact neural networks diffusely. The features extracted from EC were able to accurately classify subjects when used with linear discriminant analysis and support vector machine.

5313

Computer 87

Modulation of resting state networks after slow and periodic visual stimulation in humans

Lei Wang^{1,2,3}, Celia M. Dong^{1,2}, Alex T. L. Leong^{1,2}, Xunda Wang^{1,2}, Leon C. Ho^{1,2}, Russell W. Chan^{1,2}, Felix F. Chen³, and Ed X. Wu^{1,2}

¹Laboratory of Biomedical Imaging and Signal Processing, The University of Hong Kong, Hong Kong, Hong Kong, ²Department of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, Hong Kong, ³Department of Electrical and Electronic Engineering, Southern University of Science and Technology, Shenzhen, People's Republic of China

Periodicity is inherent in numerous external sensory stimuli. However, its effect on large-scale resting state brain networks has not been fully understood. This study investigated brain networks before and after periodic visual stimulation in low frequency (1Hz) using resting state functional MRI. Enhanced connectivity in visual, temporal, salience and ventral attention networks were detected after 1Hz visual stimulation. Furthermore, power spectrum analysis showed increase in infra-slow (<0.1Hz) rsfMRI activity. These findings suggest that slow and periodic visual stimulation initiates and/or facilitates certain neuromodulatory mechanisms such as neural oscillations, leading to increased rsfMRI connectivity.

5314

Computer 88

fMRI activation optimization in the setting of brain tumor-induced neurovascular uncoupling using resting state BOLD ALFF

Shruti Agarwal¹, Hanzhang Lu¹, and Jay J. Pillai¹

¹Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, United States

The phenomenon of neurovascular uncoupling (NVU) is an under-recognized but very important limitation of clinical BOLD fMRI because it can lead to non-visualization of eloquent cortex and resultant inadvertent surgical resection of vital brain tissue leading to permanent postoperative disability. In this study we demonstrate a novel method for correcting for the spuriously decreased ipsilesional motor activation associated with NVU through use of a novel resting state fMRI (rsfMRI) frequency domain metric-- ALFF (amplitude of low-frequency fluctuation)-- in patients with peritumoral low grade gliomas.

5315

Computer 89

Functional MRI of Brain's White Matter in Alzheimer's Disease

Xiaowei Song^{1,2}, Hui Guo^{1,3}, Sujoy Ghosh-Hajra², Careesa Liu², Yunting Zhang³, and Ryan CN D'Arcy^{1,2}

¹Health Sciences and Innovation, Fraser Health Authority, Surry, BC, Canada, ²Simon Fraser University, Burnaby, BC, Canada, ³Medical Imaging, Tianjin Medical University General Hospital, Tianjin, People's Republic of China

Impaired white matter (WM) integrity is common in Alzheimer's disease (AD), in addition to gray matter degeneration. While fMRI has been widely used in understanding the disease-associated changes, results so far have omitted the WM even though WM activation has repeatedly been reported in healthy younger adults in recent fMRI studies. Here we applied three tasks targeting interhemispheric transfer at 3.0T to extend the WM fMRI research to clinical applications in AD-dementia. The study detected fMRI activation in the corpus callosal WM in 87% individuals with early AD and normal cognitive aging (NC), and a difference between AD and NC.

Etomidate anaesthesia for fMRI in mice revisited: Subcutaneous administration facilitates experimental procedures

Rebecca Klee¹, Thomas Mueggler¹, Andreas Bruns¹, Nicole Wyttenbach¹, Antonio Ricci¹, Rodolfo Gasser¹, Markus von Kienlin¹, and Basil Künnecke¹

¹Pharma Research and Early Development, Roche Innovation Center Basel, F. Hoffmann-La Roche Ltd, Basel, Switzerland

Etomidate has recently been proposed as a hypnotic for high-fidelity fMRI in mice. It largely preserves cerebrovascular autoregulation and basal perfusion, thus providing a large window for hemodynamic-based fMRI readouts. However, commercially available formulations of etomidate come at low concentration and are suitable only for intravenous infusion, hence resulting in large infusion volumes and difficult procedures in small rodents. Here, we demonstrate that fMRI-compatible anaesthesia can be readily achieved upon subcutaneous administration of etomidate formulated as aqueous solution. We further propose to substitute etomidate with its short-acting analogue cyclopropyl-methoxycarbonyl metomidate to avert long recovery times due to subcutaneous depot formation.

5317

Computer 91

Resting state connectivity analysis for normal and abnormal physiology conditions during fMRI data acquisition

Unlike blood oxygen level dependent (BOLD)-fMRI, accurate physiologic adjustment for subjects during rs-fMRI data acquisition does not seem to be critical for the quality of the final data. In this study, we performed rs-fMRI measurements during normal and abnormal physiological conditions and analyzed betweenness centrality (BC), degree centrality (DC) and eigenvector centrality (EC). In this study, we demonstrate that physiologic conditions seem to have a direct effect on the rs-fMRI result. Thus, the results of our current study suggest that normal physiologic condition should be maintained for rs-fMRI data acquisition.

Computer 92

The Gut-Brain-Axis: from gut feelings to gut memory

Deepika Bagga^{1,2}, Karl Koschutnig², Bhageshwar Mohan³, Christoph Stefan Aigner⁴, Johanna Reichert^{1,2}, Peter Holzer^{2,5}, and Veronika Schöpf^{1,2}

¹Institute of Psychology, University of Graz, Graz, Austria, ²BioTechMed, Graz, Austria, ³Institute of Chemical Engineering, Graz University of Technology, Graz, Austria, ⁴Institute of Medical Engineering, Graz University of Technology, Graz, Austria, ⁵Institute of Experimental and Clinical Pharmacology, Medical University of Graz, Graz, Austria

The present study investigated the effect of probiotic administration on emotional memory in healthy volunteers using fMRI. The preliminary results showed that probiotic intake for 4-5 weeks improved the response accuracy significantly and this was accompanied by a decrease in the neural activity in the brain areas associated with emotions and memory formations. This decrease was more prominent for unpleasant stimuli as compared to neutral stimuli. Considering the scarce literature on gut microbiota and brain interactions in humans, our findings might provide a gateway for further understanding of mechanisms of gut-brain interactions and their effect on emotions and memory.

BOLD Signal Changes in Spinal Cord with Hypercapnia

Benjamin N Conrad^{1,2}, Satoshi Maki¹, Jennifer M Watchmaker³, Bailey A Box¹, Robert L Barry^{4,5}, Seth A Smith^{1,3}, and John C Gore^{1,3}

¹Institute of Imaging Science, Vanderbilt University, Nashville, TN, United States, ²Neuroscience, Vanderbilt University, Nashville, TN, United States, ³Radiology and Radiological Sciences, Vanderbilt University Medical Center, Nashville, TN, United States, ⁴Radiology, Athinoula A. Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Charlestown, MA, United States, ⁵Radiology, Harvard Medical School, Boston, MA, United States

A hypercapnic gas challenge was used to demonstrate blood oxygenation level dependent (BOLD) signal changes in the cervical spinal cord, and the sensitivities of two functional acquisition sequences (standard single shot (GE-EPI) and 3D multishot (3D-EPI) gradient echo EPI) were compared. Results indicated that both acquisitions were able to detect signal changes of about 1% in gray matter and higher values in white matter confirming that BOLD effects in the cord are reliable. The 3D multishot sequence exhibited higher temporal SNR and reduced susceptibility distortions, making it an attractive option for BOLD fMRI in the spinal cord.

fMRI-based brain responses to bitter and sucrose gustatory stimulation for nutrition research in the minipig model

Nicolas Coquery¹, Paul Meurice¹, Régis Janvier¹, Eric Bobillier¹, Stéphane Quéllec², Hervé Saint-Jalmes³, and David Val-Laillet¹

¹UR1341 ADNC, INRA, Saint-Gilles, France, ²UR TERE, IRSTEA, Rennes, France, ³UMR1099, INSERM, Rennes, France

The minipig model is of high interest for brain research in nutrition and associated pathologies considering the similarities to human nutritional physiology, brain structures and functions^{1,2}. In the context of a gustatory stimulation paradigm, fMRI can provide crucial information about the sensory, cognitive and hedonic integration of exteroceptive stimuli in healthy and pathological nutritional conditions. To date, this is the first intent to describe gustatory stimulation in minipigs using fMRI.

Deciphering the functional projections of the lateral hypothalamus with optogenetic fMRI
Jan Kevin Schluesener¹ and Xin Yu¹

¹Translational Neuroimaging and Neural Control Group, High-Field Magnetic Resonance Department, Max-Planck Institute for Biological Cybernetics, Tuebingen, Germany

The lateral hypothalamus (LH) is a central node of the brain to mediate brain states. It is comprised of highly heterogeneous neuronal populations and diverse projections. It remains elusive how different neuronal LH subdivisions mediate the brain state. Here, we developed an optogenetic method to map LH functional projections and investigate functional connectivity upon LH activation. Optical stimulation of the LH can directly activate the preoptic area, central thalamus and the subiculum area, and increase the cortical resting-state correlation. This work makes it possible to further target different LH neuronal populations and decipher cell-type specific functional projections.

Modeling the hemodynamic response function in rat fMRI study
Chen-You Huang¹, Chiun-Wei Huang², Shao-Chieh Chiu², Wu-Chung Shen¹, and Shin-Lei Peng¹

¹Department of Biomedical Imaging and Radiological Science, China Medical University, Taichung, Taiwan, ²Center for Advanced Molecular Imaging and Translation, Chang Gung Memorial Hospital

Previous rat fMRI studies have been analyzed by statistical parametric mapping (SPM) but the SPM is designed for human fMRI studies. In this study, we examine whether the default settings including delay time, statistic methods and hemodynamic response function (HRF) shape in SPM can directly transform to rat fMRI studies. Results show statistic methods do not affect the mapping of brain activation. However, the delay time and HRF shapes have significant impacts on extracting brain activation, especially in primary somatosensory cortex and striatum. We therefore suggest the HRF should be optimized to approach better sensitivity in other rat fMRI studies.

Accounting for serial correlation in GLM residuals during resting state fMRI nuisance regression
Molly G Bright^{1,2}, Christopher R Tench², and Kevin Murphy³

¹Sir Peter Mansfield Imaging Centre, School of Medicine, University of Nottingham, Nottingham, United Kingdom, ²Division of Clinical Neurosciences, School of Medicine, University of Nottingham, United Kingdom, ³CUBRIC, School of Physics and Astronomy, Cardiff University, United Kingdom

In resting-state fMRI nuisance regression, a General Linear Model (GLM) is employed to fit and remove the variance associated with a noise model. Without "ground-truth" knowledge, the noise models must be tested and improved to obtain accurately cleaned datasets without "throwing the baby out with the bath-water." Valid statistical inference on a GLM fit requires normally-distributed residuals, which is not the case when intrinsic brain fluctuations are present. We demonstrate that existing pre-whitening tools can be appropriately applied to account for serial autocorrelation in resting-state fluctuations during nuisance regression, allowing statistical differentiation of true and simulated noise models.

5324

Computer 3

Evaluating the impact of SNR, sampling interval and number of samples on functional sensitivity using the General Linear Model framework
Nadège Corbin¹, Guillaume Flandin¹, Oliver Josephs¹, Nick Todd², Karl J Friston¹, and Martina F Callaghan¹

¹Wellcome Trust Centre for Neuroimaging, UCL Institute of Neurology, London, United Kingdom, ²Department of Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States

In fMRI, functional sensitivity is dictated by many factors related to the data acquisition scheme, most notably image SNR, temporal resolution and the number of samples acquired. Advanced acquisition techniques, such as 2D multiband imaging, are popular for fMRI studies because they afford the possibility of greatly increasing temporal resolution allowing more samples to be acquired per unit time, but at the cost of image SNR and increased temporal auto-correlations. This study uses the General Linear Model framework to disentangle these effects and determine the net impact on functional sensitivity, as parameterised via temporal SNR and t-scores.

Spatial Adaptive Kernel Canonical Correlation Analysis
Zhengshi Yang¹, Xiaowei Zhuang¹, Tim Curran², Richard Byrd², Virendra Mishra¹, Karthik Sreenivasan¹, and Dietmar Cordes^{1,2}

¹Cleveland Clinic Lou Ruvo Center for Brain Health, LAS VEGAS, NV, United States, ²University of Colorado Boulder, CO, United States

Spatially adaptive multivariate methods were applied in fMRI activation analysis to alleviate low sensitivity in commonly used Gaussian smoothing single voxel analysis. Usually these methods require constraint to avoid the curse of high degrees of freedom. We have developed a novel spatially adaptive kernel canonical correlation analysis method, which does not require constraint and has superior performance compared to other methods.

Value of frequency domain resting state fMRI metrics ALFF & fALFF in the assessment of brain tumor induced neurovascular uncoupling
Shruti Agarwal¹, Hanzhang Lu¹, and Jay J. Pillai¹

¹Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, United States

In brain tumor patients, coupling between neuronal activity and BOLD response is often disrupted (known as neurovascular uncoupling (NVU)), resulting in dangerous underestimation of true extent of eloquent cortex in pre-surgical planning. With increasing popularity of resting state fMRI (rsfMRI) for presurgical mapping, it becomes critical to investigate effects of NVU in rsfMRI. A recent study demonstrated that tumor-related NVU can impact resting state functional connectivity within the sensorimotor network as assessed using a seed-based correlation analysis (SCA).² We now explore whether NVU may also affect the rsfMRI frequency domain metrics ALFF (amplitude of low-frequency fluctuation) & fALFF (fractional ALFF).

5327

Computer 6

The resting state fMRI regional homogeneity (ReHo) metrics KCC-ReHo & Cohe-ReHo are valid indicators of tumor-related neurovascular uncoupling
Shruti Agarwal¹, Haris I. Sair¹, and Jay J. Pillai¹

¹Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, United States

The validity of BOLD fMRI in pre-surgical planning may be severely compromised due to disruption of the normal coupling between neural activity and the consequent microvascular blood flow response (neurovascular uncoupling, or NVU). The effects of brain tumor-induced NVU on resting state BOLD fMRI (rsfMRI) have been previously described through seed-based correlation analysis (SCA). In this study, we evaluated regional homogeneity of resting state fMRI data using Kendall's coefficient of concordance (KCC-ReHo) & Coherence (Cohe-ReHo) metrics and compared these results with those of "gold standard" motor task-based (tbfMRI) activation to determine their effectiveness in detecting NVU in the sensorimotor network.

Reproducibility of Functional Connectivity Measures acquired at different times of day

Jia Fan¹, Ernesta Meintjes^{1,2}, and A Alhamud^{1,2}

¹MRC/UCT Medical Imaging Research Unit, Department of Human Biology, University of Cape Town, Cape Town, South Africa, ²Cape Universities Body Imaging Centre (CUBIC-UCT), Cape Town, South Africa

Resting state fMRI (rs-fMRI) used to detect and evaluate resting state functional connectivity (RSFC) in both healthy subjects and patients. However, the reproducibility of rs-fMRI may be influenced by the time of day when the scan is performed. In this work, we investigated the reproducibility of resting state networks by comparing scans performed in the morning (immediately after the scanner was switched on) and again in the late afternoon (after all daily scans were done) on six different days. Our results showed higher RSFC in afternoon scans in 5 regions within 5 networks.

5329

Computer 8

Investigating the feasibility of classifying independent components in resting state BOLD fMRI with sparse paradigm free mapping

Cesar Caballero-Gaudes¹, Oihane Ezama¹, Manuel Delgado-Alvarado^{2,3}, and Maria Cruz Rodriguez-Oroz^{1,4,5,6}

¹Basque Center of Cognition, Brain and Language, Donostia - San Sebastian, Spain, ²Biodonostia Health Research Institute, Donostia-San Sebastian, Spain, ³Neurology Department, University Hospital Marqués de Valdecilla, Santander, Spain, ⁴Neuroscience Area, Biodonostia Health Research Institute, Donostia-San Sebastian, Spain, ⁵Centro de Investigacion Biomedicas en Red Enfermedades Neurodegenerativas (CIBERNED), Institute Carlos III, Spain, ⁶Ikerbasque. Basque Foundation for Science, Bilbao, Spain

This work proposes a novel method for the classification of ICs in resting-state fMRI data based on sparse paradigm free mapping (PFM), a deconvolution approach that enables detecting BOLD events without prior information of their timing. This approach uses a single temporal feature, the significance of the deconvolution model estimated with PFM. Our results demonstrate that despite its simplicity this approach achieves similar sensitivity in classifying the neuronal-related BOLD components to the more complex classification method of ICA-AROMA, but with less specificity in classifying noise components. In addition, it can improve the identification of physiological noise components.

5330

Computer 9

Region-specific modeling of heart rate and respiratory volume signal contributions in whole-brain high-spatial resolution resting-state fMRI at 7 Tesla

Joana Pinto¹, Sandro Nunes¹, Marta Bianciardi², Afonso Dias¹, Luis Miguel Silveira³, Lawrence Wald², and Patricia Figueiredo¹

¹Institute for Systems and Robotics - Lisbon and Department of Bioengineering, Instituto Superior Tecnico, Universidade de Lisboa, Lisbon, Portugal, ²Department of Radiology, A.A. Martinos Center for Biomedical Imaging, MGH and Harvard Medical School, Boston, MA, United States, ³INESC-ID and Department of Electrical and Computer Engineering, Instituto Superior Tecnico, Universidade de Lisboa, Lisbon, Portugal

Several strategies have been proposed for correcting physiological noise in rs-fMRI, including different models of respiratory volume (RV) and heart rate (HR) effects. Although group-level model optimization has often been employed, it has been reported that these effects are highly variable across subjects and brain regions. Here, we investigated the impact of optimizing the time-lags of RV and HR physiological noise contributions at different levels of specificity in 7 Tesla rs-fMRI. We found that a regional optimization based on a clustering approach taking into account the time-lags' individual spatial variability explained more fMRI signal variance than group or subject-based optimizations.

5331

Computer 10

A Group level analysis to compare characteristics of balanced SSFP fMRI with non-balanced techniques

Arash Foroudi Ghasemabadi¹, Mahdi Khajehim¹, Vahid Malekian¹, and Abbas Nasiraei Moghaddam^{1,2}

¹Biomedical Engineering, Amirkabir University of Technology (Tehran Polytechnic), Tehran, Iran, ²School of Cognitive Sciences, Institute for Research in Fundamental Sciences (IPM), Tehran, Iran

Non-balanced SSFP has been recently suggested as a viable approach for T2-weighted SSFP fMRI. Compared to bSSFP, it entirely eliminates the problematic banding artifacts. However, its sensitivity has not yet been systematically investigated. In this study, fixed effects group analysis was performed on balanced and non-balanced SSFP data from seven healthy subjects in 7 T. We found that, group activation maps are generally similar, besides, mean z-values for the two methods are not significantly different. The obtained results suggest that the newly developed nbSSFP method is a viable approach to substitute bSSFP in high resolution fMRI studies.

5332

Computer 11

Relationship of seed-based connectivity and amplitude of low-frequency fluctuations in resting-state functional MRI

Parul Chachra¹, Suresh Emmanuel Joel¹, Rakesh Mullick¹, and Radhika Madhavan¹

¹GE Global Research, Bangalore, India

Resting-state functional magnetic resonance imaging (rs-fMRI) has been suggested to provide key understanding of large-scale network organization in human brain. Harnessing rs-fMRI, we have examined the relationship of seed-based connectivity (SBC) with amplitude of low-frequency fluctuations (ALFF) and fractional ALFF (fALFF). We recorded rs-fMRI from healthy volunteers and measured regional ALFF, fALFF and SBC. We demonstrate that ALFF and fALFF were weakly correlated to SBC and the correlation was specifically stronger for selected networks. Our results suggest that ALFF/fALFF and SBC may be driven by the same underlying factors and thus co-vary in a similar manner.

5333

Computer 12

Group level property of functional correlation tensor can reveal default mode network

Yang Fan¹, Jing Wang², Bingjiang Lyu³, Bing Wu¹, and Zhenyu Zhou¹

¹MR Research China, GE Healthcare, Beijing, People's Republic of China, ²Center for Medical Device Evaluation, CFDA, Beijing, People's Republic of China, ³Center for MRI Reserch, Peking University, Beijing, People's Republic of China

Recently, a novel technique was proposed directly integrated resting-state fMRI and DTI to construct a local spatio-temporal correlation tensor from resting state fMRI data. In individual level, the functional correlation tensor can be used to tract white matter fibers. However, there is no knowledge of group level property of functional correlation tensor. In the present study, group averaged tensorial properties (e.g. FA and trace) of functional correlation tensor were investigated. It is shown that the group averaged trace map of functional tensor can reveal default mode network. And our results are consistent across different datasets.

Computer 13

A Novel Multiband Multi-Echo Simultaneous ASL/BOLD Sequence for Task-Based fMRI

Alexander D. Cohen¹, Andrew S. Nencka¹, and Yang Wang¹

¹Radiology, Medical College of Wisconsin, Milwaukee, WI, United States

A novel multiband multi-echo ASL sequence was employed to collect high-resolution, whole-brain simultaneous ASL/BOLD fMRI data. Four echoes were collected allowing multi-echo independent component analysis (ME-ICA) denoising to be applied to both the BOLD and ASL data. Subjects performed a finger-tapping task, and activation was compared between datasets with and without denoising. The multi-echo denoised BOLD dataset detected the most activation compared to activation calculated using the combined echoes and only the second echo. Additional activation was observed for the denoised perfusion-weighted data compared to the original perfusion-weighted data. There was also less spurious negative activation for the PWDN data.

Computer 14

Quantitative data-driven analysis for resting-state fMRI data reveals functional connectivity differences in epilepsy patients

Yanlu Wang^{1,2}, Ivanka Savic Berglund³, Martin Uppman², and Tie-Qiang Li^{1,2}

¹Medical Radiation and Nuclear Medicine, Karolinska University Hospital, Stockholm, Sweden, ²Department of Clinical Sciences, Intervention and Technology, Karolinska Institute, Stockholm, Sweden, ³Department of Women's and Children's Health, Karolinska University Hospital, Stockholm, Sweden

Quantitative data-driven analysis (QDA) has shown to be robust and intuitive method to extract functional connectivity information from resting-state fMRI data for group-level comparison. In this study, the QDA method is applied to patients suffering from epileptic seizures. Multiple brain regions of significant ($p < 0.01$) differences were detected. The results are consistent with published works in temporal lobe epilepsy and frontal lobe epilepsy in literature using invasive methods. All brain regions experience down-regulation in functional connectivity in epilepsy patients compared to healthy control subjects.

Computer 15

A New Method of HRF Estimation Containing High Frequency Content

Xiaowei Zhuang¹, Zhengshi Yang¹, Virendra Mishra¹, Karthik Sreenivasan¹, and Dietmar Cordes^{1,2}

¹Cleveland Clinic Lou Ruvo Center for Brain Health, Las Vegas, NV, United States, ²University of Colorado Boulder, Boulder, CO, United States

A new HRF estimation method was introduced to improve the accuracy in recovering HRFs with wider frequency range. This non-smooth optimization problem was solved via BFGS technique. Results from simulated data demonstrate the accuracy and reliability of this new method in recovering HRF. Results from an event-related fMRI dataset further demonstrate the ability of the proposed method in capturing the variation of HRFs across different brain regions and subject populations.

Computer 16

Solution for Cluster Failure: Simple Method to Obtain Spatially Smooth Residuals with nearly Gaussian Auto-Correlation Functions
Kaundinya Gopinath¹, Simon Lacey², Randall Stilla², Venkatagiri Krishnamurthy¹, and Krish Sathian²

¹Department of Radiology & Imaging Sciences, Emory University, Atlanta, GA, United States, ²Department of Neurology, Emory University

Recent studies have shown that cluster-wise family-wise error rate (FWE) corrected inferences made in parametric statistical methods based fMRI studies over the past couple of decades were invalid due to incorrect these methods incorrectly specifying that spatial auto-correlation functions (sACF) of fMRI data had a gaussian shape. In this study we proposed a method to obtain fMRI inferential statistic residuals with gaussian sACF. Results show that this method substantially increases the detection power of group-level inference tests while not significantly changing the voxelwise statistic maps. Additionally it makes inferences based on assumption of gaussian SACF valid again.

5338

Computer 17

Non-linear Realignment Using Minimum Deformation Averaging for Single-subject fMRI at Ultra-high Field

Saskia Bollmann¹, Steffen Bollmann¹, Alexander Puckett², Andrew Janke¹, and Markus Barth¹

¹Centre for Advanced Imaging, The University of Queensland, Brisbane, Australia, ²Queensland Brain Institute, The University of Queensland, Brisbane, Australia

Motion dominates the contribution to variance in fMRI time series and it is therefore important to account for this variability correctly. Currently, most correction schemes use a rigid body realignment procedure, but interactions with magnetic field inhomogeneities and physiological fluctuations lead to non-linear deformations. Non-linear realignment increased spatial resolution by harvesting sub-voxel shift information with little impact on tSNR. Activated regions showed a better delineation with a clear match to anatomical features. Importantly, our proposed method can be applied to already acquired fMRI data sets to improve spatial conspicuity.

5339

Prior Knowledge Oriented Independent Component Analysis (pICA) for Component Identification in Functional MRI

Gengyan Zhao¹, Vivek Prabhakaran^{1,2}, Elizabeth M. Meyerand^{1,3}, and Rasmus Birn^{1,4}

¹Medical Physics, University of Wisconsin - Madison, Madison, WI, United States, ²Radiology, University of Wisconsin - Madison, WI, United States, ³Biomedical Engineering, University of Wisconsin - Madison, WI, United States, ⁴Psychiatry, University of Wisconsin - Madison, WI, United States

Independent component analysis (ICA), as a data-driven signal decomposition method, has been widely used in fMRI. Sources of the measurement can be separated according to the rule of maximum independency, but it usually cannot naturally generate a source which is highly correlated with the signal we are interested in. To solve this problem, we propose a new method, prior knowledge oriented ICA (pICA), to drive ICA to a set of sources with the SOI among them. Experiments of simulation and fMRI show this new method has higher specificity and accuracy in identifying the SOI and its corresponding spatial map.

The power spectrum of the functional MRI (fMRI) signal is 1/f-distributed: the power (P) is proportional to inverse frequency (1/f) with scaling factor (B), the power law exponent (PLE). The PLE, in electrophysiology, may reflect the relative balance of excitation and inhibition. Here, we examine the PLE of fMRI power spectrums in the default mode network in older adults with a clinical dementia rating score of 0, 0.5, or 1. PLE analysis may help us understand the potential regional inhibitory/excitatory balance of underlying architecture, given that the BOLD signal is a surrogate marker of local field potentials and post-synaptic processes.

Characterization of the Gray Matter Hemodynamic Response Function with High-Resolution Functional MRI

Amanda J. Taylor¹, Jung Hwan Kim¹, and David Ress¹

¹Neuroscience, Baylor College of Medicine, Houston, TX, United States

Functional magnetic resonance imaging (fMRI) measures the hemodynamic response to neural activation. Brief periods (2 s) of multisensory neural stimulation evoke the hemodynamic response function (HRF) across the majority of cerebral cortex. High (2 mm) spatial resolution enables the characterization of the HRF restricted to the gray matter, avoiding partial volume effects into nearby white matter and vascular tissue. HRF amplitude and timing measurements from eight healthy subjects showed temporal stability and stereotypical spatial amplitude patterns, suggesting that this method could be adapted to diagnose pathologies associated with abnormal neurovascular coupling.

Inflated false positive rates in fMRI depend on the voxel size of normalized images

Karsten Mueller¹, Jöran Lepsien¹, Harald E. Möller¹, and Gabriele Lohmann^{2,3}

¹Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ²Department of Biomedical Magnetic Resonance, University Hospital Tübingen, Tübingen, Germany, ³Magnetic Resonance Center, Max Planck Institute for Biological Cybernetics, Tübingen, Germany

Recently, Eklund et al published a manuscript discussing the issue of false positive results in functional MRI (fMRI) using the most common software packages. In their analysis, image upscaling was performed in fMRI preprocessing after registering images into a standard space (normalization). We show that the degree of image upscaling used for normalization impacts the statistical results when using the Gaussian Random field approach. A higher upscaling generally leads to smaller p-values increasing the number of false positive clusters. This result is quite troubling because statistical inference should not depend on a preprocessing parameter which can be chosen ad libitum.

Mondino National Neurological Institute, Pavia, Italy

In this pilot study, we investigated whether the non-linear BOLD response to varying grip force (GF) is reproduced when observing others performing the task. We used an fMRI squeezeball paradigm with two conditions: action execution (AE - subjects performed the task) and action observation (AO - subjects watched a video of the task). In both conditions, activations were detected in areas constituting the action execution-observation network and both areas evidenced linear and non-linear relations with the GF. These results indicate that action observation calls on the same context sensitive and high level processing necessary for execution.

The thalamus is a crucial node in cortical-subcortical circuits important for human emotion, cognition, and memory. While invasive studies in animals have revealed rich anatomical and functional separation of various thalamic nuclei, we sought to parse the different portions of the rat thalamus in relation to tactile (forepaw, whisker) and non-tactile (visual, olfactory) stimuli by high field fMRI (11.7T). We reproducibly detected BOLD activations of VPL, VPM, POM, dLGN, and MDT, where MDT activation is a novel indication of this structure's involvement during olfactory processing. These results have significance in understanding the role of both cortical-subcortical circuits during sensory integration.

Alteration of intrinsic brain activity in children with obstructive sleep apnea syndrome revealed by resting-state functional magnetic resonance imaging

Shuangfeng Yang¹, Shengpei Wang^{2,3,4,5}, Yue Liu¹, Wenfeng Li¹, Hongbin Li⁶, Jishui Zhang⁷, Yang Fan⁸, Hua Cheng¹, Huiguang He^{2,3,4,5}, and Yun Peng¹

¹Imaging Center, Beijing Children's Hospital, Capital Medical University, Beijing, People's Republic of China, ²The State Key Laboratory of Management and Control for Complex Systems, Institute of Automation, Chinese Academy of Sciences, Beijing, People's Republic of China, ³Research Center for Brain-inspired Intelligence, Institute of Automation, Chinese Academy of Sciences, Beijing, People's Republic of China, ⁴Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Beijing, People's Republic of China, ⁵Department of pattern recognition and intelligent system, University of Chinese Academy of Sciences, Beijing, People's Republic of China, ⁶Otolaryngology, Beijing Children's Hospital, Capital Medical University, Beijing, People's Republic of China, ⁷Neurology department, Beijing Children's Hospital, Capital Medical University, Beijing, People's Republic of China, ⁸MR Research China, GE Healthcare, Beijing, People's Republic of China

Obstructive sleep apnea syndrome (OSAS) in adults has been demonstrated to be associated with brain functional and structural changes. However, little is known about the changes in regional synchronization of spontaneous brain activity and spontaneous fluctuations in children with OSAS. In the present study, regional homogeneity (ReHo) analysis and amplitude of low-frequency fluctuation (ALFF) based on resting-state functional magnetic resonance imaging (MRI) were used to investigate spontaneous brain activity in children with OSAS compared with controls (CN). As a result, children with OSAS showed significant functional alterations of the cerebellum and temporal gyrus in children with OSAS.

Transient reduction in auditory midbrain responses following acute noise exposure

Condon Lau¹, Eddie Wong², Woody Ho¹, Bin Yang³, and Ed Wu^{2,4}

¹Department of Physics and Materials Science, City University of Hong Kong, Kowloon, Hong Kong, ²Department of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, ³Department of Radiology, Children's Hospital of Fudan University, Shanghai, People's Republic of China, ⁴Laboratory of Biomedical Imaging and Signal Processing, The University of Hong Kong, Hong Kong

Noise pollution can significantly affect sound processing, even without causing hearing loss. In this study, adult rat subjects are exposed to 100 dB sound level noise for 15 minutes. Functional magnetic resonance imaging (fMRI) and auditory brainstem response (ABR) testing with sound stimulation are performed before, 7 days after, and 14 days after exposure. ABR results show no significant threshold elevation, indicating no significant abnormalities in and near the ear. fMRI results show significant response reductions in the auditory midbrain 7 days after exposure. This suggests transient changes in central auditory gain following acute noise exposure.

Multi-Echo EPI improves olfaction-related brain activation

Sonja Blankenagel^{1,2}, Ana Beatriz Solana³, Brice Fernandez⁴, Christoph Hofstetter⁵, Andreas Dunkel⁵, Thomas Hofmann⁵, Hans Hauner^{6,7}, and Jessica Freiherr^{1,2}

¹Fraunhofer Institute for Process Engineering and Packaging (IVV), Freising, Germany, ²Diagnostic and Interventional Neuroradiology, RWTH Aachen University, Aachen, Germany, ³GE Global Research, Munich, Germany, ⁴GE Healthcare, Orsay, France, ⁵Food Chemistry and Molecular Sensory Science, Technical University of Munich, Freising, Germany, ⁶ZIEL Institute for Food and Health, Clinical Nutritional Medicine, Technical University of Munich, Munich, Germany, ⁷Institute of Nutritional Medicine, Klinikum rechts der Isar, Technical University of Munich, Munich, Germany

Multi-echo planar imaging (MEPI) was explored regarding its ability to overcome the limitations of conventional EPI imaging in studies related to olfaction. MEPI offers great sensibility even in brain regions, which are affected by susceptibility artifacts in EPI imaging. Five subjects were scanned using an event-related olfactory task with both sequences. The subsequent comparison shows that three echoes MEPI has advantages regarding olfaction-related brain activation compared to single echo EPI.

5357

Working memory improved by abacus training in Chinese children: an fMRI study utilizing a spatial n-back task

Chunjie Wang¹, Jian Weng¹, Yuqiu Liu², Hui Zhou¹, and Feiyan Chen¹

¹Department of Physics, Zhejiang University, Hangzhou, People's Republic of China, ²Department of Psychology, Zhejiang University, Hangzhou, People's Republic of China

To examine whether abacus training improves working memory (WM), sixty-four children were randomly assigned into two groups, matched for intelligence. One group received abacus training for five years while the other group had no any abacus experience. WM was measured by a n-back task. The results showed that children with training were more accurate and faster than their peers. They also had greater activation and functional connectivity in the frontoparietal regions. The findings suggest that AMC training may be an effective method to improve WM in school children, which may have implications to help individuals with cognitive deficits.

5358

Computer 37

Audio-motor interactions during musical playing with an external timing reference

Shu-Chi Pai¹, Ying-Hua Chu¹, Hui-Chuan Chang², and Jo-Fu Lin¹

¹Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, Taipei, Taiwan, ²College of Humanities and Social Sciences, Taipei Medical University, Taipei, Taiwan

Previous studies have demonstrated brain activation patterns during musical playing. However, while musical playing with multiple sources of auditory inputs is essential for musical practices and group performance, it is less understood. By using an MR-compatible piano keyboard, the present study compared musical playing with or without acoustic feedback or external timing reference. Functional MRI contrasts showed BOLD signal increase in bilateral Superior Temporal Gyrus and BA 42 during musical playing with an external timing reference, which indicates a neuronal processing pattern relating to the coordination of multiple auditory inputs.

Computer 38

Characteristics of brain spontaneous neuronal activity in chronic alcoholics using different resting-state fMRI algorithm

Yilin Zhao¹, Jun Chen¹, and Hui Lin²

¹Radiology, Renmin Hospital of Wuhan University, Wuhan, People's Republic of China, ²GE Healthcare, GE MR Research China, People's Republic of China

Resting-state fMRI reflected spontaneous baseline neuronal activity. The fractional amplitude of low frequency fluctuation (fALFF) and regional homogeneity (ReHo) method had been developed to analyze the blood oxygenation level-dependent signal fluctuations in voxelwise analysis across the whole brain. In this study, we combined two resting-state fMRI algorithms to explore the features of brain spontaneous activities in chronic alcoholics. The results indicated the abnormality activities of some nodes in the default mode network and reward circuit. It is our hope that in future studies this technique may provide the opportunity to examine the integrity of networks involving the above loops in chronic alcoholics.

BOLD-fMRI evaluation of analgesic effects on allodynia-specific pain using fibromyalgia model rats

Sosuke Yoshinaga¹, Naoya Yuzuriha¹, Yuri Kitamoto¹, Mitsuhiro Takeda¹, Hiroshi Sato², and Hiroaki Terasawa¹

¹Department of Structural Biolmaging, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan, ²Bruker BioSpin K.K., Yokohama, Japan

The aim of this study is to evaluate the effects of analgesic agents on the allodynia-specific response in an animal model of fibromyalgia. Before and after the treatment with analgesic agents, BOLD experiments using green laser stimulation were performed. Before the treatments with analgesic agents, S1, IC, and TH exhibited BOLD responses (S1: 1.1%, IC: 0.8%, TH: 0.7%). These responses were inhibited by pregabalin treatment and to a lesser extent by duloxetine treatment (S1: 0.4%, IC: not detected, TH: 0.4%). Our experimental system provides a robust preclinical and clinical evaluation system for new analgesic agents.

Representation of Taxonomic and Thematic Knowledge of the Human Brain

Yangwen Xu¹, Weiwei Men², Tianyi Qian³, Thomas Beck⁴, Jiahong Gao², and Yanchao Bi¹

¹National Key Laboratory of Cognitive Neuroscience and Learning & IDG/McGovern Institute for Brain Research, Beijing Normal University, Beijing, People's Republic of China, ²Center for MRI research, Peking University, Beijing, People's Republic of China, ³MR Collaboration NE Asia, Siemens Healthcare, Beijing, People's Republic of China, ⁴Siemens Healthcare, Erlangen, Germany

Decades of studies have identified a list of brain areas specific to a certain taxonomic category. However, neural representations incorporating both taxonomic and thematic knowledge are not well understood. In this study, we applied representational similarity analyses to investigate the underlying organizing principles of high-resolution neural activation patterns induced by different categories and themes at different cortical levels. In contrast to taxonomic representation, we did not find specific neural substrates representing thematic knowledge. Instead, neural activation patterns specific to thematic information emerged only when taxonomic differences were controlled for. These results suggest that the brain is dominated by taxonomic knowledge and then modified by thematic knowledge.

A BOLD analysis of the olfactory perception system in the mouse whole brain, using independent component analysis

Hirotsugu Funatsu¹, Fuyu Hayashi¹, Sosuke Yoshinaga¹, Mitsuhiro Takeda¹, Naoya Yuzuriha¹, Shunsuke Kusanagi¹, and Hiroaki Terasawa¹

¹Department of Structural Biolmaging, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan

A BOLD analysis can trace real-time odor responses at high spatial resolution. Rodents have well-developed olfactory systems, and thus BOLD studies have mainly been performed in rodents. However, mice have smaller brains and are more susceptible to peripheral hemodynamic changes than rats, which make it harder to obtain sufficient BOLD signals. This study revealed the real-time odor response in the mouse whole brain by the BOLD experiment with periodical odor stimulations using a high-sensitivity cryogenic probe and the high-detectability analytical method, Independent Component Analysis (ICA). The signal changes of the activation sites corresponded to the human canonical hemodynamic response function.

Repetition effects in early blind adults revealed by fMRI adaptation

Laureline Arnaud¹, Lucie Ménard², and Vincent L. Gracco^{3,4}

¹Integrated Program in Neuroscience, McGill University, Montreal, QC, Canada, ²Linguistics Department, Université du Québec à Montréal, Montréal, QC, ³School of Communication Sciences and Disorders, McGill University, Montréal, QC, Canada, ⁴Haskins Laboratories, New Haven, CT, United States

Behavioural and fMRI studies have revealed enhanced auditory abilities and differences in the brain organization of early blind individuals compared to sighted. We used fMRI to assess cortical interactions associated with speech processing of repeated and novel stimuli. Although the in-scanner behavior for the blind and sighted groups were comparable, there were a number of cortical activation and deactivation differences. Additionally, the blind participants were better at a post-scan recall task. Cross-modal recruitment of occipital areas was found in the blind participants. They also showed widespread repetition-enhancement effects, suggesting that additional attention mechanisms contribute to their enhanced auditory word encoding abilities.

fMRI detection of neuromodulation induced neuroplasticity after spinal cord injury

Vijai Krishnan^{1,2}, Anna Schwartz¹, William Stokes¹, Jeff W.M. Bulte², Jineta Banerjee², Aline Thomas², Pablo Celnik³, and Galit Pelled^{1,2}

¹F.M. Kirby Center, Kennedy Krieger Institute, Baltimore, MD, United States, ²Department of Radiology, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ³Physical Medicine and Rehabilitation, Johns Hopkins University School of Medicine, MD, United States

Spinal cord injury (SCI) leads to severe motor and sensory deficits. New advances in non-invasive neuromodulation technologies such as transcranial magnetic stimulation (TMS) have shown promise in facilitating recovery following brain injuries. Here we tested whether TMS therapy can be developed as a rehabilitative approach in a rat model of SCI. High-resolution functional MRI (fMRI) at 11.7 T was used to detect cortical activity associated with post-injury neuroplasticity. A battery of behavioral tests was used to monitor gross changes in motor behavior. Our results demonstrate that TMS therapy is beneficial in improving post-SCI functional outcomes.

Evidence of modulation of laminar profiles by contextual modulation in V1 using high-resolution fMRI

Kimberly B Weldon¹, Michael-Paul Schallmo², Philip C Burton³, Andrea N Grant⁴, and Cheryl A Olman¹

¹Department of Psychology, University of Minnesota, Minneapolis, MN, United States, ²Department of Psychology, University of Washington, Seattle, WA, United States, ³Office of the Associate Dean for Research, University of Minnesota, Minneapolis, MN, United States, ⁴Department of Neuroscience, University of Minnesota, Minneapolis, MN, United States

We characterized depth-dependent laminar profiles of surround suppression in human early visual cortex with high-resolution 7T fMRI. In a block-design participants viewed circular target stimuli (gratings defined by sinusoidal luminance modulation) surrounded by an annulus with a grating either parallel or orthogonal to the target grating. The surround was placed either adjacent to the target grating (Near) or separated from the target by 2° of visual angle (Far). Results show a similar activation profile for Parallel and Orthogonal conditions in the Far condition across depth. For the Near condition, contextual modulation occurred more in deep, rather than superficial layers.

Computer 47

Top-down modulation in a directed sensory attention task

Kevin M. Aquino¹, Rodika Sokoliuk², Rosa Sanchez-Panchuelo¹, Simon Hanslmayr², Stephen Mayhew², Karen Mullinger^{1,2}, and Susan Francis¹

¹Sir Peter Mansfield Imaging Centre, School of Physics and Astronomy, University of Nottingham, Nottingham, United Kingdom, ²Centre for Human Brain Health (CHBH), University of Birmingham, Birmingham, United Kingdom

Attentional top-down effects are known to modulate responses when spatially directing attention within sensory modality. The directing of attention between sensory modality is less well understood. Here we present fMRI data using a Posner type attention paradigm between sensory areas (visual and somatosensory). We show that the visual, somatosensory and IPS regions are recruited during attention periods, with some of these areas modulated by degree of attention. Additional IPS regions were modulated strongly with attention recruitment. This paradigm presents top-down influence on cortical regions, allowing the study of the top-down influences of attention switching between sensory modalities.

Physiological noise correction improves sensitivity, specificity, and reproducibility of resting-state functional connectivity in a reading model
Venkatagiri Krishnamurthy^{1,2,3}, Lisa C. Krishnamurthy^{2,3,4}, Dina M. Schwam⁵, Daphne Greenberg⁵, and Robin D. Morris^{3,6}

¹Dept. of Neurology, Emory University, Atlanta, GA, United States, ²Center for Visual and Neurocognitive Rehabilitation, Atlanta VAMC, Decatur, GA, United States, ³Center for Advanced Brain Imaging, GSU/GT, Atlanta, GA, United States, ⁴Dept. of Physics & Astronomy, Georgia State University, Atlanta, GA, United States, ⁵Dept. of Educational Psychology, Special Education, and Communication Disorders, Georgia State University, Atlanta, GA, United States, ⁶Dept. of Psychology, Georgia State University, Atlanta, GA, United States

Amongst several sources of noise, physiological noise (PN) from cardiac and respiratory cycles affects reliable quantification of rsFC measures such as correlation coefficient (CC). The purpose of this study is to determine the effects of PN on specificity, sensitivity and reproducibility of rsFC maps in a 'reading' model. We show that a combination of multiple methodologies to correct for such noise leads to improved signal fluctuations (tSNR) that culminates in higher specificity and sensitivity to neuronal fluctuations that are closer to actual ground truth. Applying our methodologies to a 'reading' model, we show that, irrespective of session, correction for PN results in meaningful discrimination of reading networks between typical and struggling readers.

Computer 50

On the feasibility of estimating functional connectivity from hypercapnia BOLD MRI data
Xirui Hou^{1,2}, Peiyong Liu¹, Micaela Chan³, Gagan Wig^{3,4}, Denise Park³, and Hanzhang Lu¹

¹The Russell H. Morgan Department of Radiology, Johns Hopkins School of Medicine, Baltimore, MD, United States, ²Department of Biomedical Engineering, Johns Hopkins School of Medicine, Baltimore, MD, United States, ³Center for Vital Longevity and School of Behavioral and Brain Sciences, University of Texas at Dallas, Dallas, Texas, Dallas, TX, United States, ⁴Department of Psychiatry, University of Texas Southwestern Medical Center, Dallas, TX, United States

Resting-state fMRI, particular based on Blood-Oxygenation-Level-Dependent (BOLD) signal, has been extensively used to measure functional connectivity (FC) in the brain. A recent report proposed that FC can also be evaluated from hypercapnia BOLD image. In this work, we aim to systematically compare FC derived from hypercapnia BOLD data with those obtained from traditional resting-state BOLD data in a large cohort (170 healthy participants). Our results suggest that the hypercapnia and resting-state FC maps are spatially correlated across voxels, amplitude-wise correlated across subjects.

5372

Computer 51

Community detection in resting state functional connectivity networks beyond the resolution limit
Carlo Nicolini¹, Cecile Bordier¹, and Angelo Bifone¹

¹Center for Neuroscience and Cognitive Systems, Istituto Italiano di Tecnologia, Rovereto (TN), Italy

Graph-theoretical analysis has been widely applied to study the modular organization of brain functional connectivity networks. However, existing methods suffer from a fundamental resolution limit. Here, we propose and validate a novel, resolution-limit-free approach dubbed Asymptotical Surprise. Application of this method to human resting state networks reveals the presence of heterogeneously distributed modules, corresponding to neuroanatomically and functionally plausible networks. The finer partition afforded by Asymptotical Surprise enables a more accurate identification of connector hubs, the brain regions that are thought to be responsible for the integration of functionally segregated modules into a cohesive structure.

5373

Computer 52

Structural basis of functional networks: A fMRI/DTI fusion approach in network level
Farzaneh Keyvanfard^{1,2} and Abbas Nasiraei Moghaddam^{1,2}

¹Biomedical Engineering, Amirkabir University of Technology (Tehran Polytechnic), Tehran, Iran, ²School of Cognitive Sciences, Institute for Research in Fundamental Sciences (IPM), Tehran, Iran

fMRI provides the capability of obtaining different information from various aspects of the brain. More comprehensive understanding of the brain can be achieved by combining multimodal brain imaging data. Using Diffusion Tensor Imaging (DTI) in addition to resting state fMRI (rs-fMRI), we have proposed a novel multivariate fusion approach to find supportive structural basis of brain functional networks. Two known functional networks and their counterpart structural networks were extracted through this method.

Computer 53

Bayesian Spatio-temporal Model for Brain Resting State Connectivity
Hakmook Kang¹, Hernando Ombao², Chris Fonnesebeck³, Zhaohua Ding³, and Victoria L Morgan³

¹Vanderbilt University, Nashville, TN, United States, ²University of California, Irvine, ³Vanderbilt University

Current approaches separately analyze concurrently acquired diffusion tensor imaging (DTI) and functional magnetic resonance imaging (fMRI) data. The primary limitation of these approaches is not to use all available information in estimation of resting state functional connectivity (FC). To overcome this limitation, we developed a Bayesian hierarchical spatio-temporal model that incorporated structural connectivity (SC) into estimating FC, where SC based on DTI was used to construct a prior for FC based on resting state fMRI (rs-fMRI) data. Simulations and data analysis concluded that our model achieved smaller false positive rates and was robust to data decimation compared to the conventional approach.

5375

Computer 54

Influence of temporal filtering and global signal regression on resting state networks in the rat brain
Robert Becker¹, Claudia Falfan-Melgoza¹, Jonathan Reinwald¹, and Wolfgang Weber-Fahr¹

¹RG Translational Imaging, Department Neuroimaging, Central Institute of Mental Health, Medical Faculty Mannheim / Heidelberg University, Mannheim, Germany

In a test-retest fMRI experiment we examined the influence of temporal filtering and global signal regression (GSR) on resting state networks in rats. Connectivity and topological properties as well as their test-retest reliability were assessed for eight filtering variants (with and without GSR, four frequency bands). We found GSR to strongly impair the expected structure of networks. The choice of temporal filtering frequencies whereas did not have a significant effect. Test-retest-reliability was low for all filtering variants. Based on our results we recommend to use less restrictive bandpass filters but no GSR.

5376

The Early Global Function Connectivity Stability in Infants during the Neonatal Period

Yue Cai^{1,2}, Yuan Shi³, Yang Fan⁴, Wei Gao^{5,6}, and Jiahong Gao²

¹Department of Biomedical Engineering, Peking University, Beijing, People's Republic of China, ²Center for MRI Research, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, People's Republic of China, ³Daping Hospital, Third Military Medical University, Daping Hospital, Third Military Medical University, Chongqing, People's Republic of China, ⁴MR Research China, GE Healthcare, Beijing, People's Republic of China, ⁵Biomedical Imaging Research Institute (BIRI), Department of Biomedical Sciences and Imaging, Cedars-Sinai Medical Center, Los Angeles, CA, United States, ⁶Department of Radiology and Biomedical Research Imaging Center, University of North Carolina Chapel Hill, United States

This study proposes an improved method named global functional connectivity stability (GFCS) to quantify the brain dynamic functional connectivity at a voxel-wise level. The GFCS was applied to investigate the overall functional connectivity stability and its correlation with time in infants during the period from late preterm to the term equivalent age (TEA). It is shown that infants presented high functional stability predominantly in the sensorimotor areas, temporal lobe, posterior cingulate cortex (PCC) and medial prefrontal cortex. With time, the frontal areas appeared more variable while the sensorimotor cortex appeared more stable in infants during the neonatal period.

Computer 57

Resting State Network Dynamics using Sliding-Window Detrending and Meta-Statistics: A New Approach for Real-time fMRI

Kishore Vakamudi¹, Kunxiu Gao², Cameron W Trapp³, Greg Scantlen⁴, and Stefan Posse^{5,6}

¹Neurology, Physics and Astronomy, University of New Mexico, Albuquerque, NM, United States, ²NeurInsight LLC, Albuquerque, ³Neurology, Physics and Astronomy, University of New Mexico, ⁴CreativeC LLC, Albuquerque, ⁵Neurology, Physics and Astronomy, Electrical and Computer Engineering, University of New Mexico, Albuquerque, NM, United States, ⁶NeurInsight LLC, Albuquerque, NM, United States

This study introduces a real-time confound-tolerant approach for mapping resting-state network (RSN) dynamics that is compatible with ultra-high-speed fMRI and integrates the following processing steps: (a) iterative optimization of seed selection, (b) sliding-window online detrending of confounding signals, and (c) seed-based sliding-window correlation analysis using hierarchical running averages (meta-statistics) for mapping connectivity dynamics. The method maximizes sensitivity and specificity of mapping RSNs with enhanced suppression of spurious connectivity in WM and GM. This methodology is suitable for online monitoring of data quality, for clinical applications and basic neuroscience research of resting-state connectivity, for which there are no currently available tools.

5379

Computer 58

Pseudo-bootstrap network analysis - an application in functional connectivity fingerprinting

Hu Cheng¹, Ao Li¹, Andrea Avena-Koenigsberger¹, Chunfeng Huang¹, and Sharlene Newman¹

¹Indiana University, Bloomington, IN, United States

As an alternative to template based brain parcellation in functional connectivity analysis, nearly equal-sized random parcellations are applied to individual subjects multiple times to obtain a pseudo-bootstrap sample of the functional network. As one application, the method was applied on the HCP resting state dataset to identify individuals across scan sessions based on the mean functional connectivity. With a parcellation number of 278 and bootstrap sample size of 400, an accuracy rate of ~90% was achieved by simply finding the maximum correlation of mean functional connectivity of pseudo-bootstrap samples between two scan sessions.

5380

Functional connectivity disturbances of the ascending reticular activating system in temporal lobe epilepsy

Dario J. Englot¹, Peter E. Konrad¹, Monica L. Jacobs¹, John C. Gore¹, Bassel W. Abou-Khalil¹, and Victoria L. Morgan¹¹Vanderbilt University, Nashville, TN, United States

Seizures in temporal lobe epilepsy (TLE) disturb brain network physiology and lead to brain connectivity disturbances. We used resting-state functional MRI (fMRI) recordings in TLE patients and controls to examine functional connectivity between brainstem ARAS structures and cortical/subcortical regions. ARAS connectivity was significantly lower in TLE patients than controls, with largest connectivity decreases noted in neocortical regions ipsilateral to the epileptogenic zone. Diminished ARAS connectivity was related to seizure frequency and neuropsychological impairments. Functional connectivity analysis of small brainstem structures using fMRI is feasible and may provide important information regarding mechanisms of disease in neurological disorders.

5381

Computer 60

Reproducibility of graphical measures and dynamic network features in resting state fMRI

Sue-Jin Lin^{1,2}, Tobias R. Baumeister^{2,3}, Alex MacKay^{4,5}, Irene Vavasour⁶, David K.B. Li^{5,6}, and Martin J McKeown^{1,2,6}

¹Graduate Program in Neuroscience, University of British Columbia, Vancouver, BC, Canada, ²Pacific Parkinson's Research Centre, UBC Hospital, Vancouver, BC, Canada, ³Department of Biomedical Engineering Program, University of British Columbia, ⁴Department of Physics and Astronomy, University of British Columbia, ⁵Department of Radiology, UBC Hospital, ⁶Neurology, Faculty of Medicine, University of British Columbia

Resting state fMRI (rsfMRI) has been widely used to study brain function. Numerous informative features derived from rsfMRI data have been proposed, such as graphical metrics and dynamic connectivity, but their robustness is uncertain. In order to verify their reproducibility, we acquired rsfMRI three times for 11 subjects and calculated 7 graphical measures and 7 dynamic network features. None of the measures showed significant differences among the three rsfMRI sessions. Therefore, we concluded that graphical measures and dynamic network features in rsfMRI are at least robust to inter-trial variability, which should ameliorate uncertainties when applying them to clinical research.

Frequency characteristics of resting-state fMRI functional networks

Nicole Yuen¹ and Jean Chen^{1,2}

¹Roman Research Institute, Toronto, ON, Canada, ²Medical Biophysics, University of Toronto, Toronto, ON

This study examines the frequency dependence of functional connectivity patterns as measured using resting-state fMRI (rs-fMRI). We decompose the rs-fMRI signal into its intrinsic mode functions (IMFs) using the recently proposed variational mode decomposition (VMD) technique, which provides increased frequency precision and reduced modal mixing than previous methods. We show that many functional connectivity patterns can only be seen in a certain frequency range, contrasting previous findings. We concluded that the correlation patterns are frequency dependent and are more prominent and consistent in the lower frequency range.

5384

Computer 63

Dynamic Functional Connectivity within the Default Mode Network is associated with the Complexity of its Network Nodes

Kay Jann¹ and Danny JJ Wang¹

¹Laboratory of fMRI Technology (LOFT), USC Stevens Neuroimaging and Informatics Institute, Keck School of Medicine of USC, University of Southern California, Los Angeles, CA, United States

While dynamic functional connectivity (dynFC) provides an estimate of the information transfer between brain network nodes, the signal dynamics at each node represents the local information processing. Here we assessed the relation between dynFC within the default mode network and the complexity/regularity of fMRI signal of network nodes. We found that a more complex and thus less predictable signal in a node allows for a more dynamic connectivity and hence a richer repertoire of different FC states.

5385

Computer 64

Effects of tCDS to vmPFC functional connectivity after 36 hours total sleep deprivation: a resting-state fMRI study

Li Jiyuan¹, Song Yunlong¹, Shao Yongcong², Pan Zhibin¹, Wu Yao¹, and Zhou Lu²

¹CT and MRI, The General Hospital of The Air Force People's Liberation Army, Beijing, People's Republic of China, ²Cognitive and Mental Health Research Center, Beijing Institute of Basic Medical Sciences, Beijing, People's Republic of China

There are fifteen health individuals recruited in order To explore the changes of functional connectivity in vmPFC with tDCS stimuli after 36 hours sleep deprivation. Collecting resting-state fMRI data under the tDCS stimuli and sham stimuli conditions. Using the vmPFC as the seed region, and then the time courses of all brain voxels were correlated separately with the mean time course generated from the ROI by Pearson cross-correlation. Finally, we found that tDCS can effectively mediate the dysfunction of brain connectivity.

Computer 65

White Matter Resting-State fMRI with Hypercapnic Respiratory Challenge

Tung-Lin Wu^{1,2}, Jennifer Watchmaker¹, Li Min Chen^{1,3}, Adam W Anderson^{1,2,3}, Zhaohua Ding^{1,2,3}, and John C Gore^{1,2,3}

¹Vanderbilt University Institute of Imaging Science, Nashville, TN, United States, ²Biomedical Engineering, Vanderbilt University, Nashville, TN, United States, ³Radiology and Radiological Sciences, Vanderbilt University, Nashville, TN, United States

In order to further elucidate the biophysical origins of spatio-temporal correlation tensors and validate the possibility of detecting BOLD signals in white matter, we acquired resting-state fMRI in volunteers breathing alternately room air and CO₂ enriched air to induce a hypercapnic-normoxic change in CBF and CBV. Our hypercapnic respiratory challenge experiments suggest that spatio-temporal correlations in white matter may be driven by local hemodynamic effects, consistent with BOLD effects instead of other potential mechanisms. Our results also imply and support our previous observation that BOLD signals in white matter can be reliably detected, and resting-state correlations between voxels are anisotropic.

Temporal evolution of effective connectivity analysis in anaesthetised mice

Qasim Bukhari¹, Aileen Schroeter¹, and Markus Rudin^{1,2}

¹Institute of Biomedical Engineering, ETH and University of Zurich, Zurich, Switzerland, ²Institute of Pharmacology and Toxicology, University of Zurich, Zurich, Switzerland

Dynamic functional connectivity (dFC) analysis has gained considerable interest in the past years. The goal of this technique is to estimate the temporal changes of resting state functional connectivity networks and get insights into brain pathologies by analyzing these dynamic patterns. dFC uses functional connectivity correlations as a means to understand the brain functional principle. Dynamic Causal Modeling (DCM) has been widely used in the neuroimaging community to estimate the effective connectivity by fitting a neuronal model to the observed fMRI data. Stochastic DCM together with Bayesian Model Comparison applied to resting state fMRI data results in the selection of the most plausible neuronal model explaining the observed data. The input to these model estimation methods are the full length time series extracted from the regions of interest of mouse resting state fMRI data, neglecting the temporal evolution of the model parameters. In this work we combine the two approaches by estimating the temporal changes in the effective connectivity as derived from DCM.

Stimulus-evoked fMRI activations are a subset of resting-state fMRI networks in the rat olfactory bulb

Garth J Thompson^{1,2}, Basavaraju G Sanganahalli^{1,2,3}, Keeley Baker^{4,5}, Justus V Verhagen^{4,5}, Gordon M Shepherd⁵, and Fahmeed Hyder^{1,2,3,6}

¹Radiology and Biomedical Imaging, Yale University, New Haven, CT, United States, ²Magnetic Resonance Research Center (MRRC), Yale University, New Haven, CT, United States, ³Quantitative Neuroscience with Magnetic Resonance (QNMR) Core Center, Yale University, New Haven, CT, United States, ⁴The John B. Pierce Laboratory, New Haven, CT, United States, ⁵Neurobiology, Yale University, New Haven, CT, United States, ⁶Biomedical Engineering, Yale University, New Haven, CT, United States

Are coordinated activations of the brain during sensory stimulation linked to the synchronized activations or "functional connectivity" observed with resting state fMRI? We recorded odor-stimulation fMRI and resting state fMRI in the rat olfactory bulb's glomerular sheet. Glomerular activations due to three odors were compared to spontaneous fluctuations organized as twenty-two independent component networks. Networks correlated with activation in an odor-specific manner. We reconstructed approximations of activation which retained odor specificity for two of three odors, despite being constructed from resting state data. Our results suggest a function for synchronized resting oscillations in reinforcing stimulation-specific responses.

Dynamic Functional Connectivity in Event-Related fMRI and its implications in Epilepsy

Ashish Kaul Sahib^{1,2}, Michael Erb¹, Klaus Scheffler^{1,3}, Thomas Ethofer^{1,4}, and Niels Focke²

¹Department of Biomedical Magnetic Resonance, University Hospital Tuebingen, Tuebingen, Germany, ²Department of Neurology/Epileptology, University Hospital Tuebingen, Tuebingen, Germany, ³Max-Planck-Institute for Biological Cybernetics, Tuebingen, Germany, ⁴Department of General Psychiatry, University Hospital Tuebingen, Tuebingen, Germany

To assess the impact of repetition time (TR) and window size on the temporal features of BOLD functional connectivity (FC) using a sliding window approach in event-related fMRI. In addition, test the feasibility of this approach in epilepsy. We calculated the functional connectivity degree (FCD) by counting the total number of connections of a given voxel above a predefined threshold based on Pearson correlation. In summary, we showed that dynamic FCD transients are better detectable with sub-second TR than conventional TR, indicating a potential to study the temporal characteristics of interictal epileptiform discharges and seizures in epilepsy patients.

Topological Networks reorganization in two profile of High Potential Children: a resting state fMRI study.

Ilaria Suprano¹, Chantal Delon-Martin, Gabriel Kocevar, Claudio Stamile, Salem Hannoun, Pierre Fournier, Olivier Revol, Fanny Nusbaum, and Dominique Sappey-Mariniere

¹Université Claude Bernard - Lyon 1, Lyon, France

High Potential Children diagnosis remains unclear. We proposed to examine 56 children with a resting state fMRI study. The profile of network topology was explored in two different groups of HP estimating the hub disruption index (k). A disruption of the order of importance of specific nodes in both the HP groups was found with a stronger reorganization in heterogeneous group. This results may offer a confirm of the different psychiatric characteristics that exist between the HP profiles. The sensitivity of graph metrics based on rs-fMRI was demonstrated to be very helpful to provide a better characterization of HP children.

¹Beijing Children's Hospital, Capital Medical University, Beijing, People's Republic of China, ²Chinese Academy of Sciences, Beijing, People's Republic of China, ³GE Healthcare, Beijing, People's Republic of China

It is reported that OSAS may cause cognitive function disorder of children due to chronic hypoxia for a long time [1] . However, it is not clear whether there are any structural changes of cerebral regions, e.g. white matter (WM). Diffusion kurtosis imaging is now widely used in the detection of cortical structural changes across kinds of diseases. In the present study, DKI is used to investigate microstructural changes of WM in OSAS children compared with normal healthy controls.

Graph theoretical analysis of the modular organization of resting state functional connectivity in the rat
Stefano Tambalo¹, Giulia Scuppa¹, Carlo Nicolini¹, Cecile Bordier¹, and Angelo Bifone¹

¹Center for Neuroscience and Cognitive Systems, Istituto Italiano di Tecnologia, Rovereto (TN), Italy

Modular organization of resting state functional connectivity has been demonstrated in human studies using graph theoretical approaches. Various methods, characterized by different resolutions, have enabled the investigation of the functional connectivity structure of the human brain at different scales. Here, we extend these approaches to the study of resting state connectivity in the rat, and demonstrate for the first time the existence of multi-scale, functionally segregated modules in this species.

How does chronic neuroinflammation affect resting state functional connectivity?

Esteban Adrian Oyarzabal^{1,2,3}, SungHo Lee^{1,4,5}, Manasmita Das^{1,2}, Sheng Song^{6,7}, and Yen-Yu Ian Shih^{1,2}

¹Neurology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, ²Biomedical Research Imaging Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, ³Neurobiology Laboratory, National Institute of Environmental Health Sciences, RTP, NC, United States, ⁴University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, ⁵Biomedical Research Imaging Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, ⁶Neurobiology Laboratory, National Institute of Environmental Health Sciences, RTP, NC, United States, ⁷National Institute of Environmental Health Sciences, RTP, NC, United States

Chronic neuroinflammation, present in most neuropathologies, has long-term consequences on neurocircuit connectivity synchrony and strength. By implementing multi-modal techniques to quantify neuroinflammation, we found a strong association linking the intensity of neuroinflammation with depressed functional connectivity. We partly attribute these changes to neurodegeneration and the loss of central NE.

Fluctuations of the EEG-fMRI correlation reflect intrinsic strength of functional connectivity in default mode network

Tuija Keinänen^{1,2}, Seppo Rytty², Vesa Korhonen¹, Juha Nikkinen³, Osmo Tervonen¹, Matias Palva⁴, and Vesa Kiviniemi¹

¹Diagnostic Radiology, Oulu University Hospital, Oulu, Finland, ²Clinical Neurophysiology, Oulu University Hospital, Oulu, Finland, ³Oncology and Radiotherapy, Oulu University Hospital, ⁴Neuroscience Center, University of Helsinki

Resting-state networks (RSN) functional connectivity has shown to be temporally dynamic in the brain. Also the correlations between infra slow fluctuations in electroencephalography (EEG) and blood oxygen level-dependent signal have shown dynamic variability over time. Here, we used simultaneous EEG-fMRI with ultra-fast magnetic resonance encephalography to study the link between the variations of these correlations and variations in RSN functional connectivity. The results suggest that the correlation strength is markedly linked to the strength of underlying functional connectivity. This leads to low correlations when averaged over a long period, high momentary synchrony can be reached due to intrinsic RSN dynamics.

fMRI can indirectly measure brain activity, but the biochemical underpinnings of the BOLD changes are still unknown. Nevertheless, ¹H-MRS can bridge such gap by measuring Glx [summation of glutamate (Glu) and glutamine (Gln)], where Glu is one of the mediators of neurovascular coupling. In this study, we aim to elucidate the complex relationship between attention control (numerical Stroop) and its associated neurochemical changes by combining the biochemical information from task-based fMRI and ¹H-MRS. Our result showed that the anterior cingulate cortex was positively correlated with Glx. This is the first study providing neurochemical explanation of the BOLD change during attention control task.

Empirical Model Decomposition Removes Non-stationary EEG Noise in Simultaneous fMRI-EEG Acquisition

Kevin Wen-Kai Tsai¹, Hsin-Ju Lee², Wen-Jui Kuo², Jo-Fu Lotus Lin³, and Fa-Hsuan Lin^{3,4}

¹Aim for the Top University Project Office, National Taiwan Normal University, Taipei, Taiwan, ²Institute of Neuroscience, National Yang-Ming University, Taipei, Taiwan, ³Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ⁴Department of Neuroscience and Biomedical Engineering, Aalto University, Espoo, Finland

Non-stationary EEG noise from simultaneous fMRI-EEG acquisition could be conventionally removed by optimal basis selection and followed by a low-pass filtering. An empirical model decomposition (EMD) method was applied to partially remove non-stationary EEG noise from simultaneous fMRI-EEG acquisition. Our results suggested that EMD method could reveal similar auditory evoked potential with optimal basis selection and low-pass filtering without prior knowledge or cut-off frequency, thus preserving high frequency signal not empirically related to the non-stationary noise. This EMD method allows us to investigate human brain high frequency EEG oscillation in the simultaneous fMRI-EEG measurement.

Correcting motion-affected gradient artifacts in EEG-fMRI: a modeling approach

Shuoyue Zhang¹, Bruno Riemenschneider¹, Maxim Zaitsev¹, Jürgen Hennig¹, and Pierre LeVan¹

¹Department of Radiology, Medical Physics, University Medical Center Freiburg, Freiburg, Germany

Simultaneous acquisition of electroencephalography (EEG) and functional magnetic resonance imaging (fMRI) is extensively applied for brain mapping due to the high temporal resolution of EEG and high spatial resolution of fMRI. But gradient artifacts on the EEG cannot be optimally corrected in the presence of abrupt head movements. In this work, we demonstrate a method to model motion-related gradient artifacts. Thus we obtain not only an improvement in gradient artifact correction, but also infer motion information directly from the EEG.

Computer 79

Investigation of the relationship between metabolic basis of thalamus and brain spontaneous activity revealed by a study combined fMRI and MRS

Zhengge Wang¹, Bing Zhang¹, and Bin Zhu¹

¹Radiology, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, People's Republic of China

Several recent studies have reported a correlation between regional glutamate concentration and BOLD activation. In this study, we combined resting-state fMRI and MRS to investigate whether this association maintain in spontaneous brain activity in the thalamus. Significant positive correlation was found between glutamate concentration and the ALFF and ReHo in left thalamus; negative correlation between glutamate and DC in left thalamus. Furthermore, the ALFF of left primary motor cortex and bilateral auditory cortex were affected by left thalamus glutamate. This provides insight into better understanding the neuronal and biochemical mechanisms of thalamus function.

Low frequency activity from somatosensory thalamus propagates brain-wide and modulates top-down visual processing

Alex T. L. Leong^{1,2}, Russell W. Chan^{1,2}, Xunda Wang^{1,2}, Celia M. Dong^{1,2}, Leon C. Ho^{1,2}, and Ed X. Wu^{1,2}

¹Laboratory of Biomedical Imaging and Signal Processing, The University of Hong Kong, Hong Kong, Hong Kong, ²Department of Electrical and Electronic Engineering, The University of Hong Kong, Hong Kong, Hong Kong

Top-down/descending control is a critical stage in sensory processing that underlies numerous cognitive processes. Recent studies uncovered the prevalence of converging long-range networks across multiple sensory modalities as anatomical substrates that likely mediate sensory top-down control. Using an optogenetic fMRI technique that we recently developed to examine patterns of large-scale brain-wide interactions mediated by the somatosensory thalamo-cortical network, we demonstrated that propagating low frequency activity (~1Hz) underlying such interactions enhanced visual responses in the superior colliculus. This work presents a new approach to investigate the functional roles of top-down control and their underlying brain mechanisms.

Correction of Gradient Artefacts in Simultaneous EEG-FMRI from Rotating Gradient Trajectories

Mark Chiew¹, Jostein Holmgren², Nadine N Graedel¹, Dean Fido¹, Catherine E Warnaby¹, and Karla L Miller¹

¹FMRIB Centre, University of Oxford, Oxford, United Kingdom, ²Institute of Psychology, University of Oslo

We propose a method for correcting gradient artefacts in simultaneous EEG-FMRI that are variable from shot-to-shot, where artefacts cannot be identified via averaging. The artefact model is extracted from a data-driven decomposition that identifies the signal contributions which show geometric variation matching that of the trajectory rotation model. We show that this correction, applied to a rotating EPI trajectory, works just as well as standard approaches applied to conventionally sampled (non-rotating) EPI data. This will allow the use of more flexible sampling approaches in simultaneous EEG/fMRI that facilitate highly accelerated dynamic image reconstruction.

How quickly does the human brain switch back from a task mode to the resting state condition? This question is addressed in a small sample of healthy volunteers employing a simultaneous trimodal MR-flumazenil-PET-EEG approach at 3T. Based on the fMRI results, we observe an increase in ReHo - a measure of local connectivity - coupled with a slight decrease in the binding potential of [¹¹C] Flumazenil in the PCC which is a major hub of the default mode network; this indicates a change of the GABA-ergic driven inhibitory tonus. This is accompanied with changes in the alpha band over parietal electrodes.

GABA MRS combined with resting state functional connectivity to explore decoding and fluency skills of typical and struggling readers

Lisa C. Krishnamurthy^{1,2,3}, Venkatagiri Krishnamurthy^{2,3,4}, Dina M. Schwam⁵, Daphne Greenberg⁵, and Robin D. Morris^{3,6}

¹Dept. of Physics & Astronomy, Georgia State University, Atlanta, GA, United States, ²Center for Visual and Neurocognitive Rehabilitation, Atlanta VAMC, Decatur, GA, United States, ³Center for Advanced Brain Imaging, GSU/GT, Atlanta, GA, United States, ⁴Dept. of Neurology, Emory University, Atlanta, GA, United States, ⁵Dept. of Educational Psychology, Special Education, and Communication Disorders, Georgia State University, Atlanta, GA, United States, ⁶Dept. of Psychology, Georgia State University, Atlanta, GA, United States

Previous reports have shown that resting concentrations of gamma-amino butyric acid (GABA) will predict resting state Functional Connectivity (rsFC) measures as well as amplitude of task activation. The goal of this study is to model how the neurochemical profile interplays with the connectivity underlying the decoding and fluency components of the reading circuit. Our model is in support of recent task-based fMRI observations, but goes beyond by interrogating the underlying networks that support the behavior, and combining that information with the neurochemistry that characterize the trait. These preliminary results of combining MRS and rsFC with neuropsychological measures are promising, and will help identify the underlying dysfunction in struggling adult readers' brain circuitry.

Multimodal meta-analysis of neural correlates in first-episode drug-naïve major depressive disorder

Weina Wang¹, Youjin Zhao², Xinyu Hu², and Qiyong Gong²

¹West China Hospital of Sichuan University, Chengdu, People's Republic of China, ²West China Hospital of Sichuan University, People's Republic of China

Evidence of structural and resting-state functional brain abnormalities in MDD has been inconsistent. We conducted the first multimodal meta-analysis of voxel-based morphometry (VBM) and amplitude of low-frequency fluctuation (ALFF) studies in first-episode drug-naïve MDD patients. 15 VBM data sets and 11 ALFF data sets were included. A multimodal meta-analysis was used to highlight brain regions with both structural and functional abnormalities. The multimodal meta-analysis identified conjoint structural and functional differences in the left lateral orbitofrontal cortex and right supplementary motor area. Dissociated anatomical and functional brain abnormalities in MDD were also observed. Meta-analysis revealed in MDD a complex pattern of conjoint and dissociated structural and functional brain abnormalities in brain regions involved in cognition and emotional processing.

Multimodal functional imaging using modified fMRI-weighted minimum-norm estimation

Jing Xu¹, Tianyi Qian², Thomas Beck³, and Jia-Hong Gao¹

¹Center for MRI Research, Peking University, Beijing, People's Republic of China, ²MR Collaborations NE Asia, Siemens Healthcare, Beijing, People's Republic of China, ³Application Development, Siemens Healthcare, Erlangen, Germany

Multimodal functional neuroimaging by combining fMRI and EEG has been studied to achieve high-resolution reconstruction of the spatiotemporal cortical current density (CCD) distribution. Although fMRI-constrained EEG/MEG source imaging can enhance spatiotemporal resolution of functional neuroimaging, it has been reported that hard fMRI constraint can result in misidentification of neuronal sources if mismatches exist between fMRI activations and EEG/MEG sources. In this study, we propose a new method modified fMRI-weighted minimum-norm estimation (mfMNE) to solve the problem of fMRI-EEG integrated source imaging. This method may be a promising option for solving the mismatches between fMRI and EEG/MEG in the fMRI-constrained EEG/MEG source imaging.

A Comparison of BOLD Signal Amplitude and Electrical Activity During Task Performance in MS and Healthy Control Subjects: Evidence of Neurovascular Decoupling

Mark J Lowe¹, Wanyong Shin¹, Balu Krishnan², and Lael Stone²

¹Imaging Institute, Cleveland Clinic, Cleveland, OH, United States, ²Neurologic Institute, Cleveland Clinic, Cleveland, OH, United States

Recent reports indicate that cerebrovascular reactivity (CR) may be impaired in multiple sclerosis (MS). Here we report initial studies to use simultaneous measurements of electroencephalography (EEG) and BOLD during performance of a motor task. Using EEG-derived predictors of BOLD response, we show that, while EEG robustly predicts the amplitude of the BOLD signal in healthy control subjects, the estimation is very poor in MS patients. This could be direct evidence of cerebrovascular decoupling of the BOLD signal in MS.

¹Laureate Institute for Brain Research, Tulsa, OK, United States, ²Stephenson School of Biomedical Engineering, University of Oklahoma, Norman, OK, United States, ³Center for Biomedical Engineering, University of Oklahoma, Norman, OK, United States
- In EEG-fMRI, EEG electrodes record head motions with a high temporal resolution (EEG-motion-sensor), which can be utilized for retrospective slice-by-slice fMRI motion correction. EEG motion components derived from independent component (IC) analysis were automatically identified by the common features observed in the IC mean power spectral density, spatial projection topographic map, and signal contribution. For real-time application of the EEG-motion-sensor, pre-trained models are desirable for faster classification. We used convolutional neural network to evaluate performance of motion-IC classification model. High speed and classification accuracy were achieved on a large EEG-fMRI dataset, suggesting the possibility of real-time EEG-motion-sensor applications for fMRI.

- 5414 **Computer 94** [Multi-scale peak detection method for an automatic cardioballistic artifact period determination directly from EEG-fMRI data](#)
Chung-Ki Wong¹, Qingfei Luo¹, Vadim Zotev¹, Raquel Phillips¹, and Jerzy Bodurka^{1,2,3}

¹Laureate Institute for Brain Research, Tulsa, OK, United States, ²Stephenson School of Biomedical Engineering, University of Oklahoma, Norman, OK, United States, ³Center for Biomedical Engineering, University of Oklahoma, Norman, OK, United States
- In simultaneous EEG-fMRI, the period of cardioballistic artifact (BCG) in EEG is required for the artifact removal. Recording the electrocardiogram (ECG) waveform during fMRI is difficult, often causing inaccurate period detection. Since the BCG artifact waveform in EEG-fMRI is relatively invariable compared to the ECG waveform, we propose a multiple-scale peak-detection algorithm to determine directly the BCG period from EEG-fMRI data. The algorithm achieves a high detection accuracy of the BCG artifact occurrence on a large EEG-fMRI dataset without using the ECG waveforms, virtually eliminating the need for ECG for BCG artifact removal.

- In this study, deep brain stimulation with chronically implanted electrodes in the unilateral ventral tegmental area of a monkey was performed. The purpose was to determine stimulation paradigms for a range of inter-stimulation intervals that would enable the simultaneous observation of brain activity using fMRI and endogenous dopamine release using [¹¹C]raclopride-PET. While long inter-stimulation intervals produced a unilateral focal CBV response in the striatum but no change in [¹¹C]raclopride binding, short intervals produced a more widespread CBV response and displacement of [¹¹C]raclopride. This study shows the effect of stimulation parameters on brain activity, neurotransmitter release and its limits of detectability.
-

In-Bore MRI-Guided and Monitored Laser Ablation for Renal Malignancy: Outcome Data from 46 Treated Tumors with 24-Month Median Follow-up

Sherif G. Nour^{1,2}, Kareem K Elfatairy³, Debra O Weber³, Melinda M. Lewis⁴, and Viraj A Master⁵

¹Radiology and Imaging Sciences, Emory University Hospitals and School of Medicine, Atlanta, GA, United States, ²Interventional MRI Program, Emory University Hospitals and School of Medicine, Atlanta, GA, United States, ³Radiology and Imaging Sciences, Interventional MRI Program, Emory University Hospitals, Atlanta, GA, United States, ⁴Pathology, Emory University Hospitals and School of Medicine, Atlanta, GA, United States, ⁵Urology, Emory University Hospitals and School of Medicine, Atlanta, GA, United States

Interventional MRI technology has been used to guide and monitor renal ablation procedures because of its ability to provide online feedback on ablation progress and determine treatment endpoints based of individual tumor responses. The field of Interventional MRI lacks the abundance of outcome data that provide the evidence for the added value of using MRI technology to guide interventions. We report the long-term efficacy data for interactive guidance and real-time monitoring of 46 renal ablation procedures performed entirely within an interventional MRI suite using a short introducing needle and a flexible laser fiber.

Quantitative Evaluation of Thermochemical Ablation Injections in Bovine Liver Phantoms using ²³Na MRI

Tobias Theis¹, Nicolas G. R. Behl¹, Erik N. K. Cressman², Armin M. Nagel^{1,3}, Sebastian Flassbeck¹, Aaron Kujawa¹, Peter Bachert¹, Mark E. Ladd¹, and Florian Maier¹

¹Medical Physics in Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany, ²Interventional Radiology, The University of Texas MD Anderson Cancer Center, Houston, TX, United States, ³Institute of Radiology, University Hospital Erlangen, Erlangen, Germany

Thermochemical ablation (TCA), a novel minimally invasive ablation therapy, was quantitatively evaluated using ²³Na MRI at 7T. In this study, eight TCA injection experiments were performed using eight *ex vivo* bovine liver phantoms. Normalization on the reference tubes and B₁-correction of the ²³Na images were performed to get quantitative values. This improved the maximum relative error of the estimated amount of substance by a factor of 3.6. The total injected amount was accurately determined. This study shows that quantitative ²³Na MRI provides detailed information about TCA injections, which is important for computational modelling of the method and cell damage prediction.

Computer 3

Monitoring Cryoablation using Short Inversion Recovery Ultrashort Echo Time (STIR-UTE) MRI

Junichi Tokuda¹, Kemal Tuncali¹, Ravi T Seethamraju², Clare M Tempny¹, and Ehud J Schmidt¹

¹Radiology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, United States, ²Siemens Healthcare, Boston, MA, United States

We propose a new technique to delineate the area below the critical temperature in the frozen tissue during cryoablation using STIR UTE MRI. It relies on the temperature-dependency of the T1 in the frozen tissue. We demonstrated the technique in an *ex vivo* swine kidney sample using a 3T MRI scanner with a STIR PETRA sequence. To create a uniform temperature gradient, the sample was placed between dry-ice and warm bath, while UTE and STIR UTE images were being acquired. The STIR UTE image demonstrated hyper-intensity in the frozen area, relative to hypo-intensity in the UTE image.

Field drift-correction of PRFS temperature mapping using interleaved non selective free induction decay (FID) readouts

Cyril J Ferrer¹, Lambertus W Bartels¹, Tijl van der Velden¹, Charles Mougenot¹, Chrit T.W Moonen¹, and Clemens Bos¹

¹UMC Utrecht, Utrecht, Netherlands

During long hyperthermia procedures guided by MR thermometry, drift of the main magnetic field leads to systematic errors in PRFS measurements, compromising the required temperature monitoring. In this study we evaluated if interleaving acquisition of PRFS MRT with non-selective FID readouts using conventional receive coil elements allows for correcting the drift effects in PRFS thermometry. Automated field drift correction using interleaved non-selective FIDs allowed maintaining a precision and accuracy better than 1°C. This temperature precision would typically be required for controlling a hyperthermia procedure.

MR Relaxation Properties in MR Coagulation for Vascular Repair

Ming Zhao^{1,2}, Ouri Cohen², Erez Nevo³, R.Gilberto Gonzalez², and Jerome L. Ackerman²

¹Department of Physics, University of Massachusetts Lowell, Lowell, MA, United States, ²Martinos Center, Department of Radiology, Massachusetts General Hospital, Charlestown, MA, United States, ³Robin Medical, Inc., Baltimore, MD, United States

As part of a project to develop MR-induced RF heating of a coagulable biomaterial for minimally invasive repair of vascular lesions, we investigate the relationship between the heat coagulation behavior and MR relaxation properties of egg white. This protein solution is a good model for the analogous behavior of human serum albumin solution, an optimal (but expensive) biomaterial for MR coagulation. We find that large changes in both T_2 and the width of the magnetization transfer spectrum clearly indicate the temperature at which the coagulation process occurs. T_2 and MT weighted MR images identify coagulated material in an aneurysm phantom.

In Vivo Evaluation of a Multi-echo Pseudo-Golden Angle Stack of Stars Thermometry Method

Bryant T. Svedin¹, Allison Payne¹, and Dennis L. Parker¹

¹Radiology and Imaging Sciences, University of Utah, Salt Lake City, UT, United States

A multi-echo pseudo-golden angle stack of stars sequence for use in free-breathing interventional procedures is evaluated in vivo with 5 healthy volunteers for use in MR thermometry in the breast. High spatial and temporal resolution (1.3 mm³, 1.43 s) is achieved through k-space filtering. PRF temperature, T_2^* , ρ (signal magnitude at TE = 0), respiration correction and fat/water separation are simultaneously measured. Use of a pseudo-golden angle increment allows for the removal of phase (and therefore PRF temperature) artifacts due to changing k-space sampling between reconstructed time points. k-Space sampling based phase reference library greatly improves temperature standard deviation compared to a single baseline reference.

A Methodology for Deriving Thermal Dose Model Parameters from Perioperative MR Data

Christopher MacLellan^{1,2}, David Fuentes^{1,2}, Sujit Prabhu³, Ganesh Rao³, Jeffrey S. Weinberg³, John D. Hazle^{1,2}, and R. Jason Stafford^{1,2}

¹Imaging Physics, MD Anderson Cancer Center, Houston, TX, United States, ²The University of Texas Graduate School of Biomedical Sciences at Houston, Houston, TX, United States, ³Neurosurgery, MD Anderson Cancer Center, Houston, TX, United States

Real-time damage estimates provided by Magnetic Resonance Temperature Imaging (MRTI) and appropriate thermal dose models can provide crucial feedback during of thermal ablation procedures. However, these models are not tailored to the post-treatment radiological endpoints that are used to verify the extent of the thermal lesion after therapy. A technique is developed to allow estimation of thermal dose model parameters through retrospective analysis of MRTI and post-treatment imaging. The feasibility of this technique is investigated in a protein coagulation phantom and clinical ablation data.

Computer 9

Highly accelerated Cartesian MR thermometry without parallel imaging using undersampled partial Fourier acquisition and k-space hybrid reconstruction

Rebecca E Weires^{1,2} and Will Grissom^{1,2}

¹Department of Biomedical Engineering, Vanderbilt University, Nashville, TN, United States, ²Institute of Imaging Science, Vanderbilt University, Nashville, TN, United States

Partial Fourier temperature mapping using the k-space hybrid algorithm is shown to be more accurate than conventional partial Fourier reconstruction, and the use of partial Fourier acquisition patterns improves the performance of the k-space hybrid algorithm. Undersampled partial Fourier acquisition with k-space hybrid reconstruction can be used to achieve highly accelerated, artifact-free temperature mapping with a robust Cartesian acquisition. Reconstruction is parallelized in the slice dimension and frequency-encoded dimension to achieve real-time volumetric EPI temperature mapping, without parallel imaging.

Visualization of the VIM Thalamic Nucleus using Synthesized MPRAGE Images

Jiachen Zhuo¹, Steven Roys¹, John Hebel¹, Erma Owens¹, Prashant Raghavan¹, Dheeraj Gandhi¹, and Rao P Gullapalli¹

¹Diagnostic Radiology and Nuclear Medicine, University of Maryland School of Medicine, Baltimore, MD, United States

The ventral intermediate nucleus (VIM) of the thalamus is a highly effective target for treatment of essential tremor (ET). Visualization of VIM is however challenging due to the lack of T1 or T2 MRI contrast between the various thalamic nuclei. In this study, we used synthesized MPRAGE images with varied inversion time (TI) (SynTI images) to visualize the VIM for pre-surgical planning in MRgFUS treatment of ET. Verification based on 24hr post-treatment lesion location on four patients showed good agreement from the identified VIM with lesion center.

In Vivo Targeting Accuracy Assessment of a MR-guided Focused Ultrasound Device (MRgFUS) Equipped with Tracking Coils

Sara Johnson¹, Bryant T Svedin², and Allison Payne³

¹Bioengineering, University of Utah, Salt Lake City, UT, United States, ²Physics, University of Utah, Salt Lake City, UT, United States, ³Radiology, University of Utah, Salt Lake City, UT

MR-guided focused ultrasound (MRgFUS) ablation treatments can be improved with more accurate and faster treatment planning. In this study, a fast, automatic tracking coil system is employed to predict the ultrasound transducer focus for treatment planning purposes. The accuracy of the geometric focus predictions was assessed in vivo with a breast-specific MRgFUS device. This study reports a targeting accuracy of 3.1 ± 1.4 mm, measured as the average Euclidean distance between the volumetric center of mass of thermal sonications and their predicted focal locations.

PRF temperature and velocity mapping of complex fluid flow inside a pin fin array heat exchanger

Waltraud B. Buchenberg¹, Florian Wassermann², Martin Bruscheckowski³, Sven Grundmann³, Axel J. Krafft¹, Jürgen Hennig¹, and Bernd Jung⁴

¹Department of Radiology, University Medical Center Freiburg, Medical Physics, Freiburg, Germany, ²Department of Fluid Mechanics and Aerodynamics, Technische Universität Darmstadt, Darmstadt, Germany, ³Institute of Fluid Mechanics, University of Rostock, Rostock, Germany, ⁴Interventional and Pediatric Radiology, University Hospital, Institute of Diagnostic, Bern, Switzerland

MR thermometry (MRT) and MR velocimetry (MRV) allow to non-invasively measure temperature and velocity fields. Therefore, they are well-suited to address medical questions; however, they can also be a valuable tool to study fluid flow and heat transfer phenomena in technical devices. Here, PRF temperature and velocity measurements were performed in a complex flow setup: a pin fin array consisting of multiple copper tubes which is frequently used in industrial processes for cooling purposes. MRV and MRT are excellent techniques to gain new insights into fundamental heat transfer phenomena and they greatly extend conventional tools for temperature and velocity measurements.

A fully electronically steered phased array with 4096 elements for ultrasound treatments under MRI guidance

Yuexi Huang¹, Ben Lucht¹, Rohan Ramdoyal¹, Samuel Guneseelan¹, Tyler Portelli¹, Ping Wu¹, and Kullervo Hynynen^{1,2,3}

¹Physical Sciences Platform, Sunnybrook Research Institute, Toronto, ON, Canada, ²Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada, ³Institute of Biomaterials and Biomedical Engineering, University of Toronto, Toronto, ON, Canada

A flat focused ultrasound array of 13 cm in diameter with 4096 elements was manufactured in house with center-to-center element spacing of half-wavelength at the centre frequency of approximately 500 kHz. The design allows for a much wider steering range. Feasibility for thermal ablation and hyperthermia over large target volumes was demonstrated in animal studies.

5436

Computer 20

A Three-dimensional Target Tracking Technique for MRgHIFU using an Image Matching Method with Liver Deformation Volumes Obtained via Time-Resolved Volume Acquisitions

Etsuko Kumamoto^{1,2}, Daisuke Kokuryo², and Kagayaki Kuroda^{3,4}

¹Information Science and Technology Center, Kobe University, Kobe, Japan, ²Graduate School of System Informatics, Kobe University, Kobe, Japan, ³Graduate School of Engineering, Tokai University, Hiratsuka, Japan, ⁴Center for Frontier Medical Engineering, Chiba University, Chiba, Japan

MRgHIFU treatment for liver requires a tracking technique to "lock on" to the focal spot at the target tissue region during respiratory-induced motion for targeting and temperature imaging. Here, we proposed a target tracking technique using template matching methods. A pre-operative, multi-slice sagittal image series under natural slow breathing was acquired, and a database, including a three-dimensional translation and deformation behavior of the liver and the target, was constructed. Intra-operative target tracking was performed by acquiring a single sagittal slice. The experimental results were demonstrated the feasibility of the three-dimensional target tracking technique using a template matching methods.

Variation of B1+ Homogeneity and SNR Efficiency in Select Water Bolus Designs for Transcranial MR-Guided Focused Ultrasound

Matthew R. Tarasek¹, Benny Assif², Eyal Zadicario², and Desmond T.B. Yeo¹

¹MRI, GE Global Research, Niskayuna, NY, United States, ²Insightec Ltd., Tirat Carmel, Israel

Transcranial magnetic resonance (MR)-guided focused ultrasound (tcMRgFUS) has gained prominence as a technology for treating several brain pathologies. A typical FUS applicator has a large water bolus in direct contact with the patient's head to provide (i) acoustic coupling to the patient, and (ii) a means to remove heat generated from acoustic absorption in the skull. These water bolus structures can lead to significant image artefacts. Here we use electromagnetic simulations to assess water bolus compartment designs that have different electrical properties. The goal is to downselect a design that produces improved B1+ homogeneity and SNR in a region of interest.

5438

Computer 22

Monitoring of Microbubbles Stable Cavitation in a Flowing Phantom by Using MRI

Cheng-Tao Ho¹, Chen-Hua Wu¹, Shih-Tsung Kang¹, Wen-Shiang Chen², Po-Hung Hsu³, Hao-Li Liu³, Chih-Kuang Yeh¹, and Hsu-Hsia Peng¹

¹Department of Biomedical Engineering and Environmental Sciences, National Tsing Hua University, Hsinchu, Taiwan, ²Department of Physical Medicine and Rehabilitation, National Taiwan University Hospital, Taipei, Taiwan, ³Department of Electrical Engineering, Chang-Gung University, Taoyuan, Taiwan

We aim to real-time monitor the signal intensity (SI) change of microbubbles in the presence of stable cavitation (SC) effect in a flowing phantom to comprehend the combining effects of SC and flow. Distinct reduced SI was observed, particularly in the focused ultrasound (FUS) focus and downstream regions, during transmitting FUS pulses. More substantial SI changes can be observed with increase of acoustic pressure. In this study, we verified the feasibility of using HASTE sequence to real-time monitor SI changes at the presence of SC effect of MBs in a flowing phantom.

5439

Computer 23

PRF thermometry accuracy at 7.0T for thermal MR applications with and without the presence of fat

Michal Pham¹, Yiyi Ji¹, Hendrik Paysen¹, Eva Oberacker¹, Till Huelnhagen¹, Thoralf Niendorf^{1,2,3}, and Lukas Winter¹

¹Berlin Ultrahigh Field Facility (B.U.F.F.), Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany, ²Experimental and Clinical Research Center (ECRC), a joint cooperation between the Charité Medical Faculty and the Max Delbrück Center for Molecular Medicine, Berlin, Germany, ³MRI.TOOLS GmbH, Berlin, Germany

Proton resonance frequency (PRF) shift temperature mapping is influenced by B₀ field drift, temperature dependent electromagnetic property changes that alter phase velocity, alpha calibration and temperature dependent magnetic susceptibility changes. This work details PRF thermometry at 7.0T of a thermal MR setup. In a homogeneous agarose phantom PRF reading accuracy is within the accuracy of fiber optic sensor readings (0.29±0.21)°C. Temperature dependent magnetic susceptibility changes in pure fat lead to significant temperature reading errors. However, for more realistic thermal MR applications in the human brain (ΔT<10°C, volume fat fractions< 10-20%), temperature reading accuracy is comparable to water-based samples.

Quasi MR-imaging Artefact Free ECoG and Intracortical Electrodes

Johannes B. Erhardt¹, Maria Vomero^{1,2}, Jochen Leupold³, Calogero Guelli^{1,2}, Sam Kassegne², and Thomas Stieglitz¹

¹Dep. of Microsystems Engineering, University of Freiburg, Freiburg, Germany, ²Dep. of Mechanical Engineering, San Diego State University, United States, ³Dep. of Radiology, University Medical Center Freiburg, Germany

The combination of implantable neural electrodes and fMRI holds great potential for better understanding the human brain. However, the image acquisition - especially in the vicinity of the implants - is compromised by artifacts caused by metal components. In this work we address this issue by studying different types of devices in terms of designs and materials, and by quantifying their MRI artifacts. Doing so we demonstrate the quasi artifact-free behavior of a hybrid probe combining surface and penetrating carbon electrodes into a single sheet of polyimide, after comparing it with conventional implants in high field MRI and clinical fMRI.

Adaptive SAR mass-averaging compared against thermal simulations in the presence of a titanium hip prosthesis in 7T pTx MRI

Aurelien Destruel^{1,2}, Kieran O'Brien^{2,3}, Markus Barth², Jin Jin¹, Feng Liu¹, and Stuart Crozier¹

¹School of Information Technology and Electrical Engineering, The University of Queensland, Brisbane, Australia, ²Centre for Advanced Imaging, The University of Queensland, St Lucia, Australia, ³Siemens Healthcare Pty Ltd, Brisbane, Australia

The lack of study and guidelines means there is currently no imaging of orthopaedic metal implants at 7T MRI. Local RF heating should preferably be monitored to ensure that no heating occurs close to the implant. SAR_{10g} is the current preferred method to monitor the patients' local radiofrequency exposure. This study shows that keeping SAR_{10g} under recommended values does not ensure that heating remains under safe values close to a hip prosthesis when compared with the more relevant thermal simulations. A new adaptive SAR mass-averaging approach is introduced and gives more reliable prediction of the location and magnitude of heating.

- 
- ¹MR.comp GmbH, Gelsenkirchen, Germany, ²Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ³Division of Biomedical Physics, U.S. FDA, CDRH, Office of Science and Engineering Laboratories, Silver Spring, MD, United States
- We investigated the dependence of the incident electric field (**E**) generated in the ASTM phantom on the coil losses. The results showed that magnetic field (**H**) normalized to √wbSAR, depends on capacitor **Q** factors. To avoid systematic errors in predicting the induced electric fields inside a human body the coil model should include realistic coil losses. Our results indicate that the use of ratio **E** to ||**H**|| at the coil iso-center normalization to predict **E** inside a human body located in a commercial birdcage coil based on a numerical coil model with arbitrary coil losses can result in high errors.
-
- 5448 Computer 104 **Sensitivity of the transfer function on the dielectric properties of the surrounding media: a case study**
Mikhail Kozlov^{1,2} and Wolfgang Kainz³
- 
- ¹MR.comp GmbH, Gelsenkirchen, Germany, ²Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany, ³Division of Biomedical Physics, U.S. FDA, CDRH, Office of Science and Engineering Laboratories, Silver Spring, MD, United States
- In this case study we show the dependence of the lead transfer function and the RF-induced power deposition (**P**) on the presence of heterogeneous tissues around of the lead tip. Depending on the lead length, our results shows a dramatic non-linear dependence of **P** on a small volume of a different tissue surrounding the lead tip, i.e., a fatty pocket, when using a TF derived in a homogeneous media. Thus, using TFs derived in a homogeneous media can result in large systematic errors in predicting **P**, and consequently the lead tip heating, of AIMDs inside a human body.
-
- 5449 Computer 105 **Study of RF coupling and heating in multi-wire SEEG Electrodes.**

Tanvir Baig¹, Bhumi Bhusal¹, Pallab Bhattacharyya², Stephen Jones², and Michael Martens¹

¹Physics, Case Western Reserve University, Cleveland, OH, United States, ²Cleveland Clinic Foundation, Cleveland, OH, United States

A SEEG electrode contains a number of contact points and as many number of insulated wires each following a contact. Here, we studied the coupling among the contact wires of SEEG electrode inserted into phantom, by using temperature measurements at different contact points, and varying the lengths of contact wires. From the experiment, we saw that, changing the length of one contact wire will result in change in temperature rise to other contacts also, even if wire lengths corresponding to those contacts are unchanged. This shows significant coupling among the wires at the RF frequency of 3T MRI system.

Analytical Solution for Electric Field Induced Inside Ellipsoidal Conductor by Time-Varying Magnetic Fields in MRI

Peter J Shin¹ and Daniel B Vigneron¹

¹University of California, San Francisco, San Francisco, CA, United States

An analytical, closed-form solution for the electric field induced inside an ellipsoidal conductor by time-varying gradients in MRI was developed. We applied the method to calculate the electric field for an ellipsoid centered on the isocenter having the semi-axis lengths 20 cm, 15 cm, and 40 cm in LR, AP, and SI directions. We observed that, due to the geometry, ramping up on the Y-axis resulted in the highest electric field intensity. Furthermore, we found that, when the ellipsoid is shifted in the SI direction, the electric field intensity increases approximately 100%.

High Resolution Volume Of Interest Acquisition With 3D Gradient Echo Sequence Using Reduced FOV 2D-RF Excitation Pulse.

Malek I MAKKI^{1,2}

¹MRI Research, University Children Hospital, Zurich, Switzerland, ²BioFlow, University Picardie Jules Verne, Amiens, France

We designed high spatio-temporal resolution imaging sequence by reducing the excited 3D volume to the object of interest in the slab. A fast spoiled gradient recalled echo acquisition sequence was modified by incorporating spiral selective 2DRF excitation in 2 perpendicular gradients. Three different combinations of slice-select gradient axis (XY, YZ, and XZ) were tested simultaneously in axial, coronal and sagittal prescription planes and different imaging parameters to define the best scheme that provides extremely high resolution spatial imaging, with low SAR and minimum artefact on clinically available scanner.

RF safety of an implanted port catheter in direct vicinity of a 7T transmit head coil

Oliver Kraff¹, Yacine Noureddine^{1,2}, Eileen Frerk^{1,3}, Andreas K Bitz⁴, Mark E Ladd^{1,4}, and Harald H Quick^{1,5}

¹Erwin L. Hahn Institute for MRI, University Duisburg-Essen, Essen, Germany, ²MR Safety Testing Laboratory, MR:comp GmbH, Gelsenkirchen, Germany, ³Hamm-Lippstadt University of Applied Sciences, Hamm, Germany, ⁴Medical Physics in Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany, ⁵High Field and Hybrid MR Imaging, University Hospital Essen, Essen, Germany

Potential RF-induced heating from an implanted port catheter in direct vicinity of a local transmit head coil at 7T was investigated. The assessment included direct measurements of E-field and temperature in a rectangular head/shoulder phantom filled with tissue simulating liquid as well as numerical SAR and thermal simulations in two human body models. Two different RF coils were used for the evaluation, a custom-made 8-channel head coil and the widely-available Nova Medical head coil. No evidence of RF-induced heating was found. Identical transmit power restrictions apply with or without port for both investigated RF coil types.

Assessment of specific absorption rate and temperature increase induced by artificial hip joints during MRI scans

Youngseob Seo^{1,2}

¹Korea Research Institute of Standards & Science, Daejeon, Korea, Republic of, ²Medical Physics, University of Science & Technology, Daejeon, Korea, Republic of

Heating of patients or burning of biological tissues by RF power induced by medical implants during MRI scan is a significant patient safety concern. The poor reliability and repeatability of the manufacturer-reported SAR values on clinical MRI systems have been acknowledged. High SAR and temperature change occur on both head and tail of artificial hip joints. It is essential to assess the safety of MRI system for patient with medical implant by measuring not only accurate SAR deposited in the body, but also temperature elevation due to the deposited SAR during clinical MRI.

Computer 110

Predictive modelling for Sacral Nerve Stimulation Lead heating - Pathway factors and their effect on MRI RF-induced stimulation lead heating

Scott Kalpin¹, Norbert Kaula², and Ramez Shehadeh³

¹Systems Engineering, Nuvectra Medical, Broomfield, CO, United States, ²R&D, Nuvectra Medical, Broomfield, CO, United States, ³R&D, Medical Technology Labs, La Mirada, CA, United States

A formula based methodology for predicting Sacral Nerve Stimulation lead temperatures when undergoing MRI exposures is presented. A generalized lead pathway model having 4 primary factors is used to represent the clinical placement. Twelve experimental configurations are selected based on variation of these generalized factors. Heating data measured in an MRI phantom is used to formulate an analytical model. Predictions from the model are compared against the actual data measured in MRI testing. The mean squared error for the model against the 12 test cases is 0.112 °C.

5455

Computer 111

Suitability of right angle pathway for testing RF-induced Spinal Cord Stimulation lead heating in an MRI

Scott Kalpin¹, Norbert Kaula², and Ramez Shehada³

¹Systems Engineering, Nuvectra Medical, Broomfield, CO, United States, ²R&D, Nuvectra Medical, Broomfield, CO, United States, ³R&D, Medical Technology Labs, La Mirada, CA, United States

This work evaluates the suitability of various pathway models to represent the worst-case heating for a Spinal Cord Stimulation lead when subjected to MRI RF-intensive exposure. The ideal model represents relevant pathways that a lead can take between any two points with the fewest variable factors. One model, used for evaluation of safety for Spinal Cord Stimulation (SCS) devices, describes a path with 4 variable factors – IPG starting position (Z), vertical rise of the proximal end of the lead (H1), lateral span width (W), and rise of the distal end of the lead within the central axis (H2). The “right angle” model is evaluated direct diagonal, half-way diagonal, and one in which all vertical rise is confined to the central axis of the MRI.

¹Massachusetts General Hospital, Charlestown, MA, United States, ²Radiology, Northwestern University, Chicago, IL, United States, ³Medicine, Northwestern University, ⁴Radiology, Massachusetts General Hospital, Charlestown, MA, United States, ⁵Life Science Engineering, Mittelhessen University of Applied Sciences (THM), Giessen, Germany

Despite the tremendous effort to develop MRI safety protocols to reduce complications in patients with cardiac implantable electronic devices with intact leads, almost nothing is known about the variation and extent of RF heating in patients with fractured or abandoned leads. Here we report the preliminary results of the first systematic simulation study of RF-induced SAR amplification at and around abandoned cardiac leads in patients undergoing MRI at 1.5 T and 3.0 T with different imaging landmarks.

5457

Computer 113

Spatial analysis of acoustic noise transfer function: is the noise level increased by the presence of a patient inside the imager bore during MRI? Takashi Hamaguchi¹, Tosiaki Miyati², Naoki Ohno², Tatsuhiko Matsushita³, Masanori Ozaki⁴, Tetsuya Minami⁵, Wataru Kouda⁵, and Toshifumi Gabata⁵

¹Department of Radiology, Kanazawa University Hospital, Kanazawa, Japan, ²Faculty of Health Sciences, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan, ³Department of Radiology, Kyoto University Hospital, Kyoto, Japan, ⁴MR Engineering, GE Healthcare Japan, Hino, Japan, ⁵Faculty of Medicine, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan

The purpose of our study was to evaluate the spatial distribution of a gradient-pulse-to-acoustic-noise transfer function (GPAN-TF) with and without a phantom inside the bore. This study showed that the spatial distribution of GPAN-TFs with a phantom in the bore was significantly larger than that with an empty imager. The GPAN-TF spectrum for high frequency range were increased by the phantom. Therefore, the patient would be exposed to a more unpleasant sound than conventional evaluation in an empty scanner. The multipoint analysis using GPAN-TFs revealed structural differences in respective gradient coils under a situation similar to actual MR examination.

Analytic Validation of a Computational Model of Magnetic Force in Linear Magnetic Materials

Spencer B Parent¹, William Handler², John Drozd², and Blaine A Chronik^{1,2}

¹Medical Biophysics, Western University, London, ON, Canada, ²Physics and Astronomy, Western University, London, ON, Canada

The current procedures and guidelines for testing forces on medical devices require that testing be performed in a MR setting, which is both timely and costly. To reduce test time and cost, a computational model of magnetic force was developed. Using a test case where an analytic solution of magnetic force can be applied, it is shown that for materials with magnetic susceptibility (χ) < 10^5 ppm, a computational model of magnetic force was correct within 10% error and this error decreases to less than 1% for χ < 10^4 ppm. Size of object is shown to have little effect on error.

5462

Computer 118

Comparing Transfer Functions in Different Tissues with a Spinal Cord Stimulation System for Estimation of RF Heating during MRI Scans

Xiaoyi Min¹ and Shiloh Sison²

¹St. Jude Medical, Inc, Sylmar, CA, United States, ²St. Jude Medical, Inc, Sunnyvale, CA, United States

The objective of this study is to compare transfer functions (TFs) of a Spinal Cord Stimulation (SCS) system in high permittivity media (HPM), low permittivity media (LPM) and in spinal cord by using computer simulations. For a SC model, we modeled the anatomical and conductive properties of the lower thoracic (T7-T10) spinal cord. The TF curves in HPM and in SCS follow each other closely. With a SC model, the compound tissue effect around the lead was seen. Lowering HPM conductivity would shift the curve slightly up that with the SC model for in-vivo.

Estimating acetate extracellular fraction in the rat brain using diffusion-weighted MRS and modeling of tissue microstructure

Marco Palombo¹, Masoumeh Dehghani², Nicolas Kunz³, Bernard Lanz², Rolf Gruetter^{2,3}, and Julien Valette¹

¹Molecular Imaging Research Center (MIRcen), Commissariat à l'Energie Atomique, Fontenay-aux-Roses, France, ²Laboratory of Functional and Metabolic Imaging (LIFMET), Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, ³Center for Biomedical Imaging (CIBM), Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

While most brain metabolites detected by *in vivo* MRS are intracellular, some of them, in particular energy metabolism substrates such as glucose, lactate and acetate, are also known to be significantly present in the extracellular space. Although of high metabolic significance and of practical importance for metabolic flux quantification in labeling studies, the accurate determination of the extracellular fraction remains challenging. Here we propose to use diffusion-weighted MRS combined with modeling of tissue microstructure to estimate acetate's extracellular fraction in the rat brain, which we find to be ~45%.

Computer 26

[Magnetization exchange between water and downfield metabolites in human brain at 9.4T](#)Nicole D Fichtner^{1,2}, Ioannis-Angelos Giapitzakis³, Nikolai Avdievich³, Ralf Mekte⁴, Daniel Zaldivar³, Anke Henning^{2,3}, and Roland Kreis¹

¹Depts. Radiology and Clinical Research, University Bern, Bern, Switzerland, ²Institute for Biomedical Engineering, UZH and ETH Zurich, Zurich, Switzerland, ³Max Planck Institute for Biological Cybernetics, Tuebingen, Germany, ⁴Center for Stroke Research Berlin (CSB), Charité Universitätsmedizin Berlin, Berlin, Germany

Ultra-high field strengths provide higher signal to noise ratio and improved separation of metabolites in spectroscopy, allowing for more precise characterization of peaks. In particular, this improved peak resolution may be of benefit for characterization of the downfield (5-10ppm) spectrum, which is not yet well characterized; this experiment aims to improve knowledge of downfield peaks by investigating their exchange rates and T_1 values at 9.4T, using inversion transfer experiments and metabolite cycling to allow for non-water suppressed acquisition.

[Association of NAA Resonance Frequency with Axonal Orientation](#)Andrew A Maudsley¹, Mohammed Z. Goryawala¹, and Sulaiman Sheriff¹

¹Radiology, University of Miami, Miami, FL, United States

The resonance frequencies of tissue metabolite are affected by cellular-level variations in magnetic susceptibility and the compartmentation of each metabolite. One prominent finding for ¹H MRS studies of the brain is differences of the N-Acetylaspartate (NAA) resonance frequency in white matter, which is hypothesized to reflect the inter-axonal localization of this metabolite and susceptibility variations that are dependent on the orientation of the major axonal bundles relative to the applied magnetic field. In this study, the dependence of the NAA frequency on axonal orientation was evaluated using voxel-based analysis of a whole-brain MRSI and diffusion-tensor imaging.

[MR Spectroscopy shows that high fat diet changes composition and distribution of mammary gland fat in a transgenic mouse model of breast cancer](#)Dianning He¹, Devkumar Mustafi¹, Xiaobing Fan¹, Sully Fernandez², Erica Markiewicz¹, Marta Zamora¹, Jeffrey Mueller³, Joseph Sachleben⁴, Matthew J Brady², Suzanne D Conzen⁵, and Gregory S Karczmar¹

¹Radiology, The University of Chicago, Chicago, IL, United States, ²Medicine, Adult and Pediatric Endocrinology, Diabetes, and Metabolism, The University of Chicago, Chicago, IL, United States, ³Pathology, The University of Chicago, Chicago, IL, United States, ⁴Biochemistry & Molecular Biology, The University of Chicago, Chicago, IL, United States, ⁵Medicine, Hematology and Oncology, The University of Chicago, Chicago, IL, United States

Epidemiological studies show increased risk of breast cancer associated with Western diets containing high animal fat. The aim of this study was to evaluate changes in mammary fat composition due to a high animal fat diet (HAFD), compared to a low fat diet (LFD), in a mouse model of breast cancer. Localized MR spectroscopy and high spectral and spatial resolution (HISS) MRI data were acquired at 9.4T. The saturated fat fractions **increased** and the polyunsaturated bond component **decreased** significantly in HAFD mice compared to LFD mice. Fat images obtained from HISS demonstrated increased mammary fat concentration in HAFD mice than LED mice.

Probing In Vivo Metabolite Relaxation by Linear Quantification of RF Driven Steady States

Linqing Li¹, Ningzhi Li¹, Li An¹, and Jun Shen¹

¹National Institute of Mental Health, National Institute of Health, Bethesda, MD, United States

A driven steady states technique for brain metabolite relaxation measurement is proposed. Multiple steady states driven by long pulse train were used to quantify T2 of brain metabolites in vivo. The proposed technique does not need to vary echo time of the measuring sequence such as PRESS. A simple linear equation for quantification of driven steady state spectra was derived using Bloch equations. The derived equation was verified by Bloch simulations, phantom and in-vivo experiments.

5473

Computer 33

Novel Approach for Simultaneous In Vivo ³¹P MRS Measurements in Frontal and Occipital Lobes of Human Brain with Dynamic Shimming

Byeong-Yeul Lee¹, Xiao-Hong Zhu¹, Myung Kyun Woo¹, and Wei Chen¹

¹Center for Magnetic Resonance Research, Department of Radiology, University of Minnesota Medical School, Minneapolis, MN, United States

Functional/metabolic changes in different brain regions of interest are of importance for better understanding of the pathophysiological mechanism underlying the human brain diseases. In this work, we present a novel design of the dual-channel ³¹P MRS system for simultaneous measurements of cerebral high-energy phosphate metabolism from two brain regions of interest by incorporating a new pulse sequence and two separated RF surface coils with a transistor-transistor logic (TTL) controller. By successfully implementing this method, we are able to obtain high quality *in vivo* ³¹P MR spectra from both frontal and occipital lobes within the same amount of time as the traditional method covering one brain region. From an engineering perspective, this new approach provides a cost-effective solution for *in vivo* ³¹P MRS study of multiple brain regions with a conventional single-channel transmitter-receiver configuration. Therefore, this valuable MR tool can be used in examining the cerebral energy metabolism across different brain regions, and the same approach could be employed to other spin applications.

Prior-Knowledge Quantitation of Glutamate, Glutamine, GABA, and Glutathione using Covariance J-resolved spectroscopy

Zohaib Iqbal¹ and M. Albert Thomas¹

¹Radiological Sciences, University of California - Los Angeles, Los Angeles, CA, United States

The two dimensional J-resolved spectroscopy technique is capable of resolving many metabolites in vivo from a volume of interest. However, the spectral resolution along the indirect dimension is generally very poor in these acquisitions. One solution is to apply a covariance transformation along the indirect dimension to yield a resulting Covariance J-resolved (CovJ) spectrum with high spectral resolution. While spectral resolution is enhanced, currently there are no methods available to fit the non-linear aspects of the covariance reconstruction. Here, we have developed a non-linear fitting algorithm capable of yielding Glutamate, Glutamine, GABA, and Glutathione concentrations in vivo using CovJ spectra.

Spectral-Dephasing based Non-Local Means for Spatially Adaptive Denoising in 3D-MRSI

Dhritiman Das^{1,2}, Eduardo Coello^{1,2}, Axel Haase¹, Rolf F. Schulte², and Bjoern H. Menze¹

¹Technical University of Munich, Garching, Germany, ²GE Global Research, Munich, Germany

We present a data-driven technique for denoising 3D Magnetic Resonance Spectroscopic Imaging (MRSI) data. Our proposed method involves a novel spectral de-phasing and re-phasing approach which increases the phase dimension of the spectra to deal with the arbitrary complex phase in the data. This is coupled with an anisotropic non local means (NLM) filter-based pattern-recognition across the multi-slice data to select similar spectra patches having a similar phase for denoising. We show that our method leads to a mean SNR improvement by an average factor of 4.5 while preserving the spectral resolution of the metabolites.

5476

Computer 36

Absolute quantification of brain metabolites by 1H-MRSI using gradient echo imaging of ~2s as a concentration reference: initial findings

Eva Heckova¹, Bernhard Strasser¹, Michal Považan^{1,2}, Gilbert Hangel¹, Siegfried Trattnig^{1,2}, and Wolfgang Bogner^{1,2}

¹High Field MR Centre, Medical University of Vienna, Vienna, Austria, ²Christian Doppler Laboratory for Clinical Molecular MR Imaging, Vienna, Austria

The unsuppressed internal water signal is a standard reference method used for quantification of brain metabolites in 1H-MRSI, however it requires additional water unsuppressed acquisition, which is in case of MRSI time demanding. Therefore we compared the performance of water signal reference acquired with unsuppressed MRSI and with ~2s long gradient echo imaging integrated into MRSI sequence. Our findings indicates that gradient echo imaging can be used as a concentration reference for 1H-MRSI.

Computer 37

Simple and general automatic quality control of 3D 1H MRSI data of the prostate using intrinsic spectral properties

Nassim Tayari¹, Jiri Obels¹, Thiele Kobus¹, Tom W.J. Scheenen¹, and Arend Heerschap¹

¹Department of Radiology and Nuclear Medicine, Radboud university medical center, Nijmegen, Netherlands

Proton 3D MR spectroscopic imaging (MRSI) provides spatial metabolic information of the prostate for improved cancer detection, localization, and staging. Clinical application of MRSI of prostate requires automatic quality control of spectra. We propose Qratio, a ratio balancing constructive spectral components of choline and citrate signals with destructive elements of lipid signals, water residuals and noise. We demonstrate that Qratio can serve as a general, fast and automated tool for quality control of prostate MRSI data, independent of field strength (1.5-7T) and acquisition protocol. The Qratio can be displayed as maps and performs with an accuracy of $88\pm 3\%$ and $AUC=0.93$.

5478

Computer 38

Quality Control of MRSI data using efficient data labelling

Nuno Pedrosa de Barros¹, Richard Iain McKinley¹, Roland Wiest¹, and Johannes Slotboom¹

¹SCAN / Neuroradiology, University Hospital Bern (Inselspital), Bern, Switzerland

MRSI-data frequently contains bad-quality spectra, what can prevent proper quantification and consequently lead to data misinterpretation. Machine-learning based methods have been proposed for automatic quality control of MRSI-data with performance levels identical to expert's manual-checking and that can classify thousands of spectra in a matter of a few seconds. Besides this, a considerable amount of time needs to be spent labelling data required to train these algorithms. Here we present a method that allows to actively select those spectra that carry the most information for the classification, allowing to reduce drastically the amount of time needed for labelling.

5479

Computer 39

Ghostbusters for MRS: Automatic Detection of Ghosting Artifacts using Deep Learning

Sreenath P Kyathanahally¹, Andre Doering¹, and Roland Kreis¹

¹Depts. Radiology and Clinical Research, University of Bern, Bern, Switzerland

Ghosting artifacts in spectroscopy are problematic since they superimpose with metabolites and lead to inaccurate quantification. Detection of ghosting artifacts using traditional machine learning approaches with feature extraction/selection is difficult since ghosts appear at different frequencies. Here, we used a "Deep Learning" approach, that was trained on a huge database of simulated spectra with and without ghosting artifacts that represent the complex variations of ghost-ridden spectra. The trained model was tested on simulated and in-vivo spectra. The preliminary results are very promising, reaching almost 100% accuracy and further testing on in-vivo spectra will hopefully confirm its ghost busting capacity

5480

Phase-rotation acquisition to study imperfections of PRESS

Sophie M. Peereboom¹, Maximilian Fuetterer¹, and Sebastian Kozerke¹

¹Institute for Biomedical Engineering, University and ETH Zurich, Zurich, Switzerland

A phase-rotation acquisition scheme is able to separate different signals in PRESS. In this work phase-rotation PRESS measurements were complemented by simulations to assess origins of spectral distortions in cardiac spectroscopy. Simulations show that, when using a phase-rotation acquisition scheme for PRESS without spoilers, more motion is acceptable when pulses are better calibrated. However, because of non-ideal pulse profiles, spoilers cannot be fully omitted if moving tissue is studied. It is shown that phase-rotation acquisition can, by combining simulations and measurements, be used as an elegant tool to investigate spectral distortions and optimize sequence parameters in PRESS of moving tissue.

Impact of time sample selection and model function design on the quantification of fatty acid composition: in vitro and in vivo studies.

Angeline Nemeth¹, H el ene Ratiney¹, Benjamin Leporq¹, Amandine Coum^{2,3}, Giulio Gambarota^{2,3}, Kevin Seyssel⁴, B er enice Segrestin⁵, Pierre-Jean Valette⁶, Martine Laville⁵, and Olivier Beuf¹

¹Univ. Lyon, INSA-Lyon, Université Claude Bernard Lyon 1, UJM-Saint Etienne, CNRS, Inserm, CREATIS UMR 5220, U1206, F69621, Lyon, France, ²INSERM, UMR 1099, Rennes, France, ³Univ Rennes 1, LTSI, Rennes, France, ⁴Department of Physiology, Faculty of Biology and Medicine, University of Lausanne, Lausanne, Switzerland, ⁵Centre de Recherche en Nutrition Humaine Rhône-Alpes (CRNH-RA), Centre Hospitalier Lyon Sud, Pierre-Bénite, Lyon, France, ⁶Hospices Civils de Lyon, Département d'imagerie digestive, CHU Edouard Herriot, Lyon, France

Interest in the follow-up of fatty acid composition (saturated, polyunsaturated and monounsaturated fatty acid) in the body is growing. Quantitative MR spectroscopy can give access to this fat composition. Today, several quantification methods are used (e.g LCMoDel, AMARES). However the statistical outcome issued from a quantitative analysis of the lipid signal can be greatly influenced by the used quantification method. We analyze 1) the impact of the time sample selection and design of the model function on the parameter identifiability 2) the quantification results obtained with different quantification models on acquisitions performed *in vitro* (oils) and *in vivo* (subcutaneous adipose tissue).

5484 Computer 44 A Novel Method for Absolute Metabolite Quantification of 1H Spectroscopic Imaging in the Human Brain Based on Water Measurement with Ultrashort TE

Michal Bittšanský¹, Milada Kováčová², Oliver Štrbák¹, Petra Hnilicová¹, and Dušan Dobrota³

¹Biomedical Center Martin, Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia, ²Faculty of Mathematics, Physics and Informatics, Comenius University, Bratislava, Slovakia, ³Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia

We introduce an easily implementable quantification method *in vivo* based on unsuppressed water measurement (pulse-acquire FID sequence with low flip-angle, short TE and TR and geometry identical to metabolite MRSI). Our quantification is practically independent on water relaxation times, requires only short extra measurement time and is robust enough in pathologies like tumors. We tested its results in a homogeneous phantom, healthy volunteers and tumor patients using a head resonator and an 8-channel array coil for acquisition.

5485 Computer 45 Water lineshape fitting method to overcome B0 field inhomogeneity for NMR spectroscopy
Donghyun Hong¹, Seyedmorteza Rohani Rankouhi¹, Jan-Willem Thielen¹, and David G. Norris^{1,2}

¹Erwin L. Hahn Institute for Magnetic Resonance Imaging, University of Duisburg-Essen, Essen, Germany, ²Donders Institute for Brain, Cognition and Behavior, Radboud University, Nijmegen, Netherlands

Good B0 field homogeneity is an essential requirement for NMR single voxel spectroscopy. Previously proposed spectral fitting method assumes that all metabolite signals have a Lorentzian shape. However, B0 inhomogeneity may both broaden the linewidth, and modify the lineshape into an asymmetric form. This study has demonstrated a water lineshape fitting method to overcome B0 inhomogeneity using corresponding metabolite fitting models by water lineshape. We obtained similar relative metabolite signal intensities and improved spectral fitting quality regardless of the field homogeneity condition.

5486 Computer 46 Repeatability of myocardial creatine and triglyceride concentration measurements with 1H-MRS
Adrianus J. Bakermans¹, Paul de Heer^{1,2}, Gustav J. Strijkers³, S. Matthijs Boekholdt⁴, Aart J. Nederveen¹, and Jeroen A.L. Jeneson^{1,5}

¹Department of Radiology, Academic Medical Center, Amsterdam, Netherlands, ²C.J. Gorter Center for High Field MRI, Department of Radiology, Leiden University Medical Center, Leiden, Netherlands, ³Department of Biomedical Engineering and Physics, Academic Medical Center, Amsterdam, Netherlands, ⁴Department of Cardiology, Academic Medical Center, Amsterdam, Netherlands, ⁵Neuroimaging Center, University Medical Center Groningen, Groningen, Netherlands

Changes in myocardial total creatine (tCr) and triglyceride (TG) content have been linked to the pathogenesis of cardiomyopathy. An assessment of repeatability for absolute quantification of myocardial [tCr] and [TG] is required for ¹H-MRS to be employed for longitudinal monitoring of therapeutic efficacy. This work reports intra- and inter-exam repeatability of [tCr] and [TG] measurements with ¹H-MRS at 3 Tesla. Our results indicate that the repeatability of the ¹H-MRS assay will be sufficient to detect a >50% depletion of the tCr pool, and >50% changes in myocardial TG levels with 95% confidence in a single subject.

5487 Computer 47 Accurate determination of cerebral lactate and glutamate concentration changes during a long visual stimulus
Carolina Fernandes¹, Bernard Lanz¹, Chen Chen¹, and Peter Morris¹

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom

Estimation of metabolic changes during neuronal activation represents a challenge for *in vivo* MRS, particularly in the case of lactate, whose dissociation from other resonances is not straightforward. To reliably quantify lactate, the lipid and macromolecular signals were significantly reduced by using a long TE (144 ms) and the remaining macromolecular signals in the vicinity of the lactate peak were individually fitted with Lorentzian peaks. Statistically significant changes in lactate and glutamate levels during 15 min of visual stimulation were detected in the visual cortex, unveiling a distinctive metabolic response pattern, which can provide further insight into brain activation mechanisms.

5488 Computer 48 Full Density Matrix Simulation of Spatially Localized Magnetic Resonance Spectroscopy
Yan Zhang¹, Li An¹, and Jun Shen¹

¹National Institute of Mental Health, Bethesda, MD, United States

Numerical simulations of three-dimensionally localized MRS spectra have been very time-consuming for multi-spin systems because the current state-of-the-art requires computation of a large ensemble of spins pixel-by-pixel in three dimensional space. In this abstract it was found that spatial coordinates of the full set of spin density operators labeled by slice selection gradients can be projected onto one dimension after slice selection as long as the crusher gradients are refocused. Therefore, the conventional three-dimensional simulation can be converted to a one-dimensional problem in cases such as the commonly used PRESS or STEAM. The proposed method was implemented using a computer program written in Java language.

Correlation of Diffusion Weighted Imaging and Echo Planar Correlated Spectroscopic Imaging of Breast Cancer in 3T
Rajakumar Nagarajan^{1,2}, Maithili Gopalakrishnan², Amir Huda³, Melissa Joines², Nanette Debruhi², and Michael A Thomas²

¹Human Magnetic Resonance Center, Institute for Applied Life Sciences (IALS), University of Massachusetts, Amherst, MA, United States, ²Radiological Sciences, University of California Los Angeles, Los Angeles, CA, United States, ³Physics, California State University, Fresno, CA, United States

In vivo magnetic resonance spectroscopy (MRS) of the breast can be used to measure the level of choline-containing compounds, which is a biomarker of malignancy. The advantage of four dimensional (4D) echo-planar correlated spectroscopic imaging (EP-COSI) enables full slice coverage of the breast facilitating recording of multi-voxel based two-dimensional (2D) MRS than the single-voxel based localized correlated spectroscopy (L-COSY). Also in addition to differentiate malignant from benign, EP-COSI can differentiate the healthy fatty from glandular. Decreased ADC values derived from diffusion weighted imaging (DWI) can be correlated with increased choline and decreased lipids quantified by the EP-COSI technique.

Improving the quality of DW spectra in the supraclavicular fossa with a navigator-gated and cardiac-triggered flow-compensated diffusion-weighted STEAM MRS acquisition

Dominik J. Weidlich¹, Andreas Hock², Stefan Ruschke¹, Daniela Franz¹, Hans Hauner³, Ernst J. Rummeny¹, and Dimitrios C. Karampinos¹

¹Department of Diagnostic and Interventional Radiology, Technical University Munich, Munich, Germany, ²Philips Healthcare, Hamburg, Germany, ³Else Kröner Fresenius Center for Nutritional Medicine, Technical University Munich, Munich, Germany

Measuring in vivo blood perfusion within the brown adipose tissue depot of the human supraclavicular fossa is highly relevant in metabolic and obesity research. DW-MRS can probe perfusion properties by measuring the IVIM signal of the water peak. However, DW-MRS of the supraclavicular fossa remains a challenging task due to the high sensitivity of the region to motion and the associated poor spectral quality. The present work proposes a DW-MRS methodology with a flow compensated acquisition combining cardiac and respiratory tracking to improve spectral quality. IVIM results for the water peak are shown for the first time in the supraclavicular fossa.

Simultaneous Hadamard Editing of GABA and glutathione

Muhammad Gulamabbas Saleh^{1,2}, Georg Oeltzschner^{1,2}, Kimberly L. Chan^{1,2,3}, Nicolaas A.J. Puts^{1,2}, Mark Mikkelsen^{1,2}, Michael Schär^{1,2}, Ashley D. Harris^{4,5}, and Richard A.E. Edden^{1,2}

¹Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²F. M. Kirby Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD, United States, ³Department of Biomedical Engineering, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ⁴Department of Radiology, University of Calgary, Calgary, AB, Canada, ⁵Child and Adolescent Imaging Research Program, Alberta Children's Hospital Research Institute, Hotchkiss Brain Institute, University of Calgary, Calgary, AB, Canada

Hadamard Encoding and Reconstruction of MEGA-Edited Spectroscopy (HERMES) allows the simultaneous, separable editing of GABA and GSH, the two most frequently edited metabolites. Rather than a two-step ON/OFF encoding of MEGA editing, HERMES uses a four-step Hadamard encoding matrix to orthogonally edit multiple metabolites. We demonstrate the method through simulations, phantom and in vivo experiments. HERMES provides excellent separation of GABA and GSH with a two-fold reduction in scan time, while maintaining spectral quality and SNR, compared to sequentially acquired measurements of GABA and GSH using MEGA-PRESS.

5493

Computer 53

Real-time frequency and motion corrected Hadamard encoded spectral editing (CHASE)

Anouk Marsman¹, Vincent Oltman Boer¹, Mads Andersen², and Esben Thade Petersen^{1,3}

¹Danish Research Centre for Magnetic Resonance, Centre for Functional and Diagnostic Imaging and Research, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark, ²Philips Healthcare, Copenhagen, Denmark, ³Dept. Electrical Engineering, Technical University of Denmark, Denmark

Inhibitory neurotransmitter GABA and antioxidant GSH are suggested to be implicated in psychiatric and neurological disorders. These metabolites can be measured in the human brain in vivo using edited ¹H-MRS. However, traditional MEGA editing can only be performed for one metabolite at a time, whereas Hadamard encoded spectral editing assesses both metabolites in one sequence, thereby reducing total scan time twofold. As the relatively small GABA and GSH signals as well as the Hadamard paradigm are highly susceptible to frequency drift and motion, real-time frequency and motion correction was added to the sequence.

5494

Computer 54

The use of MEGA-sLASER with J-refocusing echo time extension to measure the proton T₂ of lactate in healthy human brain at 7 TChen Chen¹, Bernard Lanz¹, Carolina Fernandes¹, Susan Francis¹, Penny Gowland¹, and Peter Morris¹

¹Sir Peter Mansfield Imaging Centre, University of Nottingham, Nottingham, United Kingdom

The challenges in T₂ measurement of lactate (Lac) in healthy brain tissue include J-modulation, signal overlaps and low concentration. To overcome these and characterize Lac T₂ relaxation in normal brain tissue at 7T (for the first time), this study used a MEGA-sLASER sequence with J-refocusing echo time extension. The measured T₂ value of Lac was 182±10 ms in healthy human brain (occipital lobe), which can be used for absolute quantification of Lac. The measured T₂ of NAA (169±8 ms) agrees with previous 7T reports. With high sensitivity, this approach showed its potential in detecting changes in Lac T₂ in pathology.

5495

Inter and intra-subject repeatability study of GABA Editing using MEGA-PRESS and ImSpecial Sequence

Meng Gu¹, Ralph Hurd², Laima Baltusis³, and Daniel Spielman¹

¹Radiology, Stanford University, Stanford, CA, United States, ²GE Healthcare, Menlo Park, CA, United States, ³Center for Cognitive and Neurobiological Imaging, Stanford University, Stanford, CA, United States

GABA editing with frequency-insensitive macromolecule suppression using improved MEGA-SPECIAL sequence (ImSpecial) has been developed. By using a very frequency-selective editing pulse with a pulse width of 30 ms, macromolecule was suppressed without applying a lysine-symmetric editing. An inter and intra-subject repeatability studies were conducted to evaluate GABA editing with MEGA-PRESS and ImSpecial. Compared with GABA+/Cre levels using MEGA-PRESS, GABA+/Cre levels using ImSpecial is about 40% less with lower variations for both inter and intra-subject repeatability studies, demonstrating significant MM suppression achieved using ImSpecial.

5496

Computer 56

Regional GABA concentration comparison in the human brain with the interleaved short TE sLASER and MEGA-sLASER sequence at 7T

Donghyun Hong¹, Seyedmorteza Rohani Rankouhi¹, Jan-Willem Thielen¹, and David G. Norris^{1,2}

¹Erwin L. Hahn Institute for Magnetic Resonance Imaging, University of Duisburg-Essen, Essen, Germany, ²Donders Institute for Brain, Cognition and Behavior, Radboud University, Nijmegen, Netherlands

GABA is challenging to resolve due to j-couplings and overlapping signals. Previously proposed GABA editing and short TE approach at UHF make it possible to measure relative GABA concentration. We measured GABA concentration with the interleaved sequence at various brain regions, and found an optimal method to estimate GABA in terms of spectral fitting quality. Occipital cortex showed a high GABA concentration, and GABA editing approach gave a reliable spectral fitting quality.

5497

Computer 57

J-difference editing of Creatine in the human brain

Kimberly Chan^{1,2,3}, Richard Edden^{2,3}, and Peter Barker^{2,3}

¹Biomedical Engineering, Johns Hopkins School of Medicine, Baltimore, MD, United States, ²Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins School of Medicine, Baltimore, MD, United States, ³F. M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD, United States

In vivo proton spectra, Creatine (Cr) and phosphocreatine are usually regarded as non-coupled spin systems (1). This abstract reports on the observation of a small coupling between the creatine CH₂ (3.91 ppm) and CH₃ (3.02 ppm) groups. A series of J-difference edited experiments were performed both in a phantom and in the human brain to demonstrate that a coupling exists. This coupling was found to have a coupling constant of 0.28 Hz in an isotropic phantom and an even greater coupling in a white matter region.

5498

Computer 58

Investigating the effect of phase cycling schemes on GABA-edited spectroscopy using MEGA-PRESS

Jia-Ren Lin¹, Jih-Ling Liang¹, Yi-Ru Lin¹, Cheng-Wen Ko², and Shang-Yueh Tsai³

¹Department of Electronic and Computer Engineering, National Taiwan University of Science and Technology, Taipei, Taiwan, ²Department of Computer Science and Engineering, National Sun Yat-sen University, Kaohsiung, Taiwan, ³Research Center for Mind, Brain and Learning, National Chengchi University, Taipei, Taiwan

The application of phase cycling scheme in combination with interleaved off-odd switch has been suggested for MEGA-PRESS method in many previous reports but the effect of phase cycling schemes on the spectral shape of GABA peak and on the GABA quantification has not been studied yet. Here, performance of phase cycling by different number of steps were and by modified interleaved scheme were compared. The results show that phase cycling is necessary to be applied prior interleaved on-off switch and minimum shape cycling steps are suggested to minimize subtraction artifacts possibly resulting from on-off frequency drift and motion.

5499

Computer 59

MEGA-PRESS for simultaneous aspartate and glutamate quantification at 3T.

Petr Menshchikov^{1,2}, Tolibjon Akhadov², Il'ya Melnikov², and Natalia Semenova^{1,2}

¹Semenov Institute of Chemical Physics, Russian Academy of Sciences, Moscow, Russian Federation, ²Clinical and Research Institute of Urgent Pediatric Surgery and Trauma, Moscow, Russian Federation

Direct Asp observation using PRESS, STEAM etc. in the human brain is strongly complicated by J-evolution and overlapping with other metabolites. In this work we have adjusted MEGA-PRESS for simultaneous Asp and Glu estimation. According to Vespa simulation as well as phantoms and in vivo studies TE=115ms was chosen as the best for Asp (2.65 and 2.80 ppm) and Glu (2.13 ppm) quantification without overlapping. Asp is the main precursor of neuronal marker NAA. NAA have been shown to be reduced in many disorders. Using this method allows accurate investigation of this important metabolic pathway.

Computer 61

Homonuclear spectral editing to measure ectopic lipid composition in vivo with ¹H-MRS

Lucas Lindeboom^{1,2} and Robin de Graaf³

¹Dept. of Human Biology/Human Movement Sciences, NUTRIM school for Nutrition and Translational Research in Maastricht, Maastricht University Medical Center, Maastricht, Netherlands, ²Dept. of Radiology, NUTRIM school for Nutrition and Translational Research in Maastricht, Maastricht University Medical Center, Maastricht, Netherlands, ³Dept. of Radiology and Biomedical Imaging, Magnetic Resonance Research Center, Yale University School of Medicine, New Haven, CT, United States

¹H-MRS has been used extensively to measure the total amount of lipids stored in organs like skeletal muscle and liver and it has been found that these so called ectopic fat stores are associated with insulin resistance. The role of the composition of these lipid stores (e.g. saturated vs. unsaturated fatty acids) in metabolic disturbances is unclear. Here we show the feasibility of spectral editing techniques to characterize lipid composition in adipose tissue and skeletal muscle in vivo. Estimations of lipid composition with our approach are in line with invasive biopsy studies.

5502

Computer 62

Local metabolites of healthy human brain measured with whole brain spectroscopic imaging and with single voxel spectroscopy - a study to compare different ¹H-MRS data acquisitions and data analyses

Birte Schmitz¹, Andrew A Maudsley², Sulaimann Sherif², Heinrich Lanfermann¹, and Xiao-Qi Ding¹

¹Institute of Diagnostic and Interventional Neuroradiology, Hannover Medical School, Hannover, Germany, ²Department of Radiology, University of Miami School of Medicine, FL, United States

Local metabolite concentrations in 60 healthy volunteers were estimated from EPSI data that were analyzed from individual voxel measurements and using spectral integration over a ROI and compared to results from single-voxel acquisitions. Linear regression analysis was used to estimate age-dependence of metabolite concentrations obtained with each of the three different methods. The results were compared with each other for quantitative evaluation of EPSI acquisition at short TE for detection of brain metabolites.

5503

Computer 63

Integration of Water Referencing with Water Suppression for Absolute Quantification of High-Speed MR Spectroscopic Imaging

Akram Etemadi Amin¹, Elena Ackley², Kevin Fotso², Stephen R Dager³, and Stefan Posse^{2,4,5}

¹Physic and Astronomy, U New Mexico, Albuquerque, NM, United States, ²Neurology, U New Mexico, Albuquerque, NM, United States, ³Radiology, U Washington, Seattle, WA, United States, ⁴Physics and Astronomy, U New Mexico, Albuquerque, NM, United States, ⁵Electrical and Computer Engineering, U New Mexico, Albuquerque, NM, United States

We present a new approach with negligible impact on overall scan time that integrates a short water reference acquisition and navigators into the water suppression module, to spatially and spectrally encode the water signal before suppression. We show that this approach enables quantitative 2D and 3D high-speed MR spectroscopic imaging (MRSI) of brain metabolites, for range of pre-localization techniques (slice-selective, slab-selective or PRESS), at short and long TE, and at different slice locations. This method significantly reduces the acquisition time of volumetric MR spectroscopic imaging and is compatible with a wide range of spectroscopic acquisition methods.

Computer 70

Optimal Echo Time for In-Vivo Glutamate Detection at 7T Using semi-LASER 1H-MRS

Dickson Wong^{1,2}, Amy Schranz^{1,2}, and Robert Bartha^{1,2}

¹Medical Biophysics, The University of Western Ontario, London, ON, Canada, ²Centre for Functional and Metabolic Mapping, Robarts Research Institute, London, ON, Canada

At ultra-high field (7T), the quantification of glutamate by ¹H-MRS is more accurate and precise than at lower field strengths. The semi-LASER ¹H-MRS pulse sequence has advantages at high field but requires the use of relatively long radio frequency pulses to reduce power deposition. Typically, the shortest achievable echo times (TE) are sub-optimal for glutamate detection. In this study, the optimal TE for glutamate detection was estimated by time-domain simulation and verified against in-vivo measurements. Using simulations, the optimal TE was found to be 125 ms. In-vivo measurements in one subject produced a result of ~102 ms. Both results suggest that the glutamate signal is greater at longer TEs (100-125 ms) when using semi-LASER at 7T compared to the shortest achievable TEs (40-60 ms).

5511

Computer 71

Robust detection of 2-hydroxyglutarate at 7T high field with a fully adiabatic LASER sequence

Morteza Esmaeili^{1,2} and Ovidiu Cristian Andronesi¹

¹Athinoula A. Martinos Center for Biomedical Imaging, Department of Radiology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, ²Department of Circulation and Medical Imaging, Norwegian University of Science and Technology, NTNU, Trondheim, Norway

With increasing number of high field 7T MR systems in clinical setting, the potential of using advanced MR modalities such as MR spectroscopy is increasing. Imaging 2-hydroxyglutarate (2-HG) can genotype IDH mutations in gliomas. However, the MR signal of this metabolite is overlapped with other resonances, hampering robust quantification of 2-HG. Here we optimized the timing of LASER sequence for robust detection of 2-HG at high field 7T in the presence of B₁ inhomogeneity.

5512

Computer 72

Effects of Iron Content on J-edited ¹H MRS Measures of Cortical Glutathione Investigated In Vivo with Quantitative Susceptibility Mapping (QSM)

Kofi M. Deh¹, Xiangling Mao¹, Yize Zhao², Guoxin Kang¹, Pascal Spincemaille¹, Yi Wang¹, and Dikoma C. Shungu¹

¹Radiology, Weill Cornell Medicine, New York, NY, United States, ²Healthcare Policy and Research, Weill Cornell Medicine, New York, NY, United States

As the primary intracellular antioxidant, glutathione (GSH) is involved in free radical reactions *in vivo* involving paramagnetic iron II/III as catalysts or cofactors, suggesting that findings low tissue GSH by MRS could reflect T₂ signal loss due to differences in iron content, rather than a genuine antioxidant deficit. This study estimated brain iron content using QSM to assess whether GSH deficits previously reported in patients with chronic fatigue syndrome (CFS) were genuine or simply a T₂ signal loss. No iron content differences were found between patients and controls, supporting a genuine GSH deficit in CFS.

Computer 75

High resolution MRSI using compartmental low rank algorithm: demonstration using undersampled EPSI

Ipsita Bhattacharya¹, Ralph Noeske², Baolin Yang³, Rolf F Schulte⁴, and Mathews Jacob¹

¹Department of Electrical and Computer Engineering, The University of Iowa, Iowa City, IA, United States, ²GE Healthcare, Postdam, Germany, ³GE Healthcare, Waukesha, WI, United States, ⁴GE Global Research, Munich, Germany

Improved spatial resolution is the need of the hour for MRSI. In this work we propose an algorithm which provides a comprehensive and automatic approach to recover high resolution metabolite maps from highly undersampled acquisitions; the improved spatial resolution translates to improved spectral quality and reduced leakage artifacts. The proposed algorithm is also quite flexible and can be readily used in a variety of sequences, including EPSI, CSI, and spirals acquisition schemes.

5516

Computer 76

Evaluation of Compressed Sensing reconstructions of 3D Echo Planar Spectroscopic Imaging using TV, Wavelet-\$\$\$ell_{1}\$\$\$ and TV+Wavelet-\$\$\$ell_{1}\$\$\$ based regularization.

Andres Saucedo¹, Zohaib Iqbal¹, Manoj K. Sarma¹, and M. Albert Thomas¹

¹Radiological Sciences, University of California, Los Angeles, Los Angeles, CA, United States

Magnetic Resonance Spectroscopic Imaging (MRSI) is a valuable tool to characterize metabolic concentrations and changes in several spatial locations in a single recording. However, the long acquisition time of conventional three-dimensional (3D) MRSI limits its practical application. Non-uniformly sampled 3D echo planar spectroscopic imaging (EPSI) has been proposed to accelerate the scan time, combined with compressed sensing (CS) to retain reconstruction fidelity. We apply the novel approach of reconstructing 3D EPSI data by applying TV, Wavelet-\$\$\$ell_{1}\$\$\$ and TV + Wavelet-\$\$\$ell_{1}\$\$\$ CS-based regularization on both the combined spectral and two undersampled spatial dimensions. These three reconstruction methods were evaluated in both simulated and in retrospectively undersampled data of a brain phantom.

Computer 77

Low-Rank TGV Reconstruction of High-Resolution 1H-FID-MRSI of whole brain slices

Antoine Klausner¹, Dimitri Van De Ville^{1,2}, and François Lazeyras¹

¹Department of Radiology and Medical Informatics, University of Geneva, Geneva, Switzerland, ²Institute of Bioengineering, École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

High resolution MRSI data were acquired with 2D FID-MRSI at 3T and a post-processing including lipid suppression, low-rank approximation and TGV-reconstruction is proposed. The resulting metabolic images of tNAA, tCre, Cho, Ins and Glx showed a substantial gain in quality, CRLB values associated and the SNR. This effect was particularly marked for lower signal metabolite: Ins and Glx. In addition, the proposed post-processing reconstructed efficiently under-sampled data allowing a 2- or 4-fold acquisition acceleration.

5518

Computer 78

Macromolecule Mapping with Ultrashort-TE Acquisition and Metabolite Spectral Prior

Fan Lam¹, Yudu Li^{1,2}, Bryan Clifford^{1,2}, and Zhi-Pei Liang^{1,2}

¹Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign, Urbana, IL, United States, ²Department of Electrical and Computer Engineering, University of Illinois at Urbana-Champaign, Urbana, IL, United States

This work presents a novel method for macromolecule mapping and quantification. The proposed method integrates an FID-based MRSI acquisition with a generalized series (GS) model based extrapolation scheme. The FID acquisition allows for the use of ultrashort echoes and short repetition times for fast imaging with improved SNR efficiency. The GS model effectively makes use of the spectral priors from single voxel spectroscopy and allows for reformulating the back-extrapolation of metabolite signals as a linear problem (in contrast to conventional nonlinear methods). Results from in vivo experiments demonstrate that MM signals estimated by the proposed method are consistent with an inversion recovery based method and lead to better metabolite quantification.

Covariance Five Dimensional Echo Planar J-resolved Spectroscopic Imaging

Zohaib Iqbal¹ and M. Albert Thomas¹

¹Radiological Sciences, University of California - Los Angeles, Los Angeles, CA, United States

Chemical shift imaging is a very important method used to investigate several pathologies in vivo. A recent technological development incorporating an echo planar readout, a non-uniform sampling scheme, and an iterative, non-linear reconstruction is the five dimensional echo planar J-resolved spectroscopic imaging (5D EP-JRESI) method. While this technique is capable of obtaining 3 spatial and 2 spectral dimensions in vivo, the indirect spectral dimension has a low spectral resolution, which may hinder accurate metabolite quantitation. In this study, a novel approach using a covariance transformation after reconstruction is assessed and compared to the 5D EP-JRESI method.

Comparison of different acceleration methods for high-resolution metabolite mapping using 1H FID MRSI at 9.4T

Sahar Nassirpour^{1,2}, Paul Chang^{1,2}, and Anke Henning^{1,3}

¹MPI for Biological Cybernetics, Tuebingen, Germany, ²IMPRS for Cognitive and Systems Neuroscience, Eberhard Karls University of Tübingen, Tuebingen, Germany, ³Institute of Physics, Ernst-Moritz-Arndt University Greifswald, Greifswald, Germany

Reliable metabolite mapping of the human brain using ultra-short TE and TR ¹H FID-MRSI is possible at ultra-high fields. However, MRSI studies with high spatial resolutions and brain coverage suffer from long scan times. To make these studies clinically relevant, different acceleration methods are used at the price of losing SNR. The aim of this study is to implement and compare different in-plane acceleration methods: SENSE, GRAPPA and compressed sensing for high-resolution metabolite mapping of the human brain at 9.4T without lipid suppression.

Density Weighted Concentric Circle Trajectories for Brain MRSI at 7T

Lukas Hinger¹, Bernhard Strasser¹, Philipp Moser¹, Gilbert Hangel¹, Siegfried Trattning^{1,2}, and Wolfgang Bogner¹

¹High Field MR Centre, Medical University of Vienna, Vienna, Austria, ²Christian Doppler Laboratory for Clinical Molecular MR Imaging, Medical University of Vienna, Vienna, Austria

A density weighted concentrically circular echo-planar trajectories readout scheme is presented for brain MRSI at 7 T. We give an analytic solution for the variable radii distribution in order to intrinsically measure a Hamming weighted k-space. A comparison with post acquisition filtered equidistant concentric circles is done. In vivo metabolic maps and spectra are shown.

Metabolite-Cycling Short-Echo Time Magnetic Resonance Spectroscopic Imaging using a Concentric Ring k-space Trajectory
Uzay E Emir¹, Brian Burns², Mark Chiew¹, Peter Jezzard¹, and Albert Thomas³

¹Oxford Centre for Functional MRI of the Brain (FMRIB), University of Oxford, Oxford, United Kingdom, ²Department of Oncology, University of Oxford, Oxford, United Kingdom, ³Department of Radiological Sciences, University of California, Los Angeles, CA, United States

In this study, the feasibility of acquiring and quantifying short-echo (TE = 14 ms), two-dimensional (2D) STEAM MRSI spectra from the motor cortex was demonstrated by utilizing a non-water-suppressed metabolite-cycling technique. The increase in measurement time by the metabolite-cycling is counterbalanced by a time-efficient concentric ring k-space trajectory. High quality spectra were acquired from 36 localized 2mL voxels in 8 minutes. The metabolite spectra and estimated concentrations were in agreement between non-water-suppressed and water-suppressed MRSI techniques. Findings of this study demonstrate that a non-water-suppressed metabolite-cycling MRSI technique can perform robustly on clinical MRI scanners and within a clinically feasible acquisition time.

Full-field-of view GM and WM spectroscopy in vivo using spatial lipid pattern estimation and BASE-SLIM localization
Peter Adany¹, In-Young Choi^{1,2,3}, and Phil Lee^{1,2}

¹Hoglund Brain Imaging Center, University of Kansas Medical Center, Kansas City, KS, United States, ²Department of Molecular & Integrative Physiology, University of Kansas Medical Center, ³Department of Neurology, University of Kansas Medical Center

The presence lipids of several orders of magnitude higher concentrations than metabolites in the extracranial tissues present significant challenges for the reliable acquisition and quantification of 1H MRSI, especially in the outer perimeter areas of the brain. We developed a novel spatial lipid reconstruction technique to remove nuisance lipid signals in 1H MRS. We applied lipid reconstruction to MRSI data and performed BASE-SLIM localization on the lipid-subtracted signal. Using this method, high quality compartment spectra of GM and WM could be obtained.

Computer 84

Multi-region Semi-Adiabatic Spectral-Spatial Spectroscopic Imaging (SASSI) sequence for accelerated MRSI at 7T
Rebecca Emily Feldman¹ and Priti Balchandani¹

¹Translational and Molecular Imaging Institute, Icahn School of Medicine at Mount Sinai, New York, NY, United States

High field MRI permits us to leverage increased signal-to-noise ratio (SNR) and spectral separation between metabolite peaks for more sensitive metabolite detection at higher spatial resolutions. However, the acquisition of high-resolution spectral grids can be prohibitively time intensive. Accelerated MRSI acquisitions are challenged by the limitations at 7T. We develop a multi-region SPSP excitation pulse and use it to create a novel low power, B₁ insensitive multi-region SASSI sequence with minimal chemical shift to enable accelerated MRSI.

IRREGULAR SPIRAL ACQUISITION FOR COMPRESSIVE SENSING IN MRSI

Jabrane Karkouri^{1,2}, Fabien Millioz¹, Magalie Viallon¹, Rémy Prost¹, and H el ene Ratiney¹

¹Universit e de Lyon, INSA-Lyon, Universit e Claude Bernard Lyon 1, UJM-Saint Etienne, CNRS, Inserm, CREATIS UMR 5220, U1206, F-69621, LYON, France, Lyon, France, ²Siemens Healthineers, Saint-Denis, France

Magnetic resonance spectroscopic imaging (MRSI) has multiple interests in clinical practice but it faces quite long acquisition time in practice which limits their use in a clinical environment. In this work, a new fast Magnetic Resonance Spectroscopic image acquisition method, based on Compressed Sensing and the a priori known support of the metabolites chemical shift, is introduced and evaluated based on a k-t space spiral sampling. In the real-world noisy scenario the error in the recovered spectrum highly depends on the acquired samples. We reduce this error to an acceptable level by selecting irregularly the samples using the Sequential Backward Selection algorithm. Our method has been applied on an in vivo 31P acquisition, to prove the feasibility of the proposed approach.

Computer 86

Prospective frequency correction using outer volume suppression-localized navigator for MR Spectroscopic Imaging
Chu-Yu Lee¹, In-Young Choi^{1,2,3}, and Phil Lee^{1,3}

¹Hoglund Brain Imaging Center, University of Kansas Medical Center, Kansas City, KS, United States, ²Department of Neurology, University of Kansas Medical Center, Kansas City, KS, United States, ³Department of Molecular & Integrative Physiology, University of Kansas Medical Center, Kansas City, KS, United States

Data acquisitions for magnetic resonance spectroscopic imaging (MRSI) require a long scan time to increase SNR and for spatial encoding. During the prolonged scan time, maintaining a constant static magnetic field (B0) is important for a robust MRSI measurement. However, frequency drifts occur over time even in advanced MR systems and become larger when high shim currents or rapidly switched gradients are applied. The frequency drift causes broad and distorted spectral lineshapes, reduced SNR, and quantification errors. These effects can be mitigated retrospectively and prospectively. However, in MRSI measurements, these effects can only be mitigated using the prospective frequency correction, because each spectrum is phase-encoded. The prospective frequency correction is typically achieved by incorporating a PRESS-based interleaved reference scan (PRESS-IRS) as a navigator, termed as PRESS-IRS navigator. A small excitation flip angle (10-20°) is used for the PRESS-IRS navigator to reduce the saturation-induced SNR loss on metabolite signals. Nonetheless, the SNR loss remains unavoidable and becomes notable when the imperfect refocusing pulses or a short repetition time (TR) are used in MRSI. In this study, a new prospective frequency correction method is introduced. The new method utilizes the outer volume suppression-localized navigator, termed OVS-localized navigator, resulting in no perturbations of metabolite signals and thus no saturation-induced SNR losses. Meanwhile, a precise measurement of the frequency drift and the effective correction is achieved. The presented method was demonstrated in two-dimensional (2-D) MRSI measurements under the large frequency drift induced by a fMRI experiment.

Motion Correction for 1H-MRSI of the Brain Using Unsuppressed Water Signals

Bryan Clifford^{1,2}, Xi Peng^{2,3}, Yudu Li^{1,2}, Zhi-Pei Liang^{1,2}, and Fan Lam²

¹Electrical and Computer Engineering, University of Illinois at Urbana-Champaign, Urbana, IL, United States, ²Beckman Institute for Advanced Science and Technology, Urbana, IL, United States, ³Paul C Lauterbur Research Center for Biomedical Imaging, Shenzhen Institutes of Advanced Technology, Shenzhen, People's Republic of China

Head motion poses a significant problem in MRSI experiments, especially for 1H-MRSI of the brain performed without water or lipid suppression. In this work we propose a practical method specifically designed to track head motion and correct for its effects on 1H-MRSI data acquired without water suppression. By using the companion spectroscopic water signals, we are able to track head motion with navigators collected in circular and linear trajectories. A specialized data processing scheme is also proposed for processing the navigator data along with the unsuppressed spectroscopic water signals to determine the motion parameters.

Computer 89

Lipid Suppression in 3D Magnetic Resonance Spectroscopic Imaging

Mohammed Goryawala¹, Andrew A Maudsley¹, and Sulaiman Sheriff¹

¹University of Miami, Miami, FL, United States

Proton MR spectroscopic imaging (MRSI) is complicated by the presence of subcutaneous lipids, which, if not suppressed before Fourier reconstruction, cause ringing in metabolite maps due to limited k-space sampling. In this study inversion recovery (IR) based lipid suppressed acquisition was compared to non-lipid suppressed acquisition combined with two methods for reducing lipid ringing in whole brain MRS imaging. Results indicate non-lipid suppressed acquisition using the T2-regularization or Papoulis-Gerchberg algorithm for reconstruction is possible without significant ringing artifacts, however, can have a detrimental effect on spectral linewidth and baseline, resulting in smaller spatial coverage than IR based lipid-suppressed acquisition.

A Minimum-Phase Shinnar-Le Roux Spectral-Spatial Excitation RF Pulse for Water and Lipid Suppression in 1H MRSI of Body Extremities

Kexin Deng¹, Chao Ma², Kui Ying³, and Georges El Fakhri²

¹Biomedical Engineering, Tsinghua University, Beijing, People's Republic of China, ²Gordon Center for Medical Imaging, Radiology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, ³Engineering Physics, Tsinghua University, Beijing, People's Republic of China

It is challenging to remove nuisance water and lipid signals in 1H-MRSI of body extremities. Strong lipid signals exist both in the subcutaneous layer and bone marrow but also in the muscle, i.e., intramyocellular and extramyocellular lipids. This work presents a novel minimum-phase Shinnar-Le Roux (SLR) spectral-spatial excitation RF pulse for both water and lipid suppression in 1H-MRSI of body extremities. We have validated the proposed method using Bloch equation simulation, phantom, and in vivo studies.

5531

Spatial Hadamard encoding of J-edited spectroscopy using slice-selective editing pulses

Kimberly Chan^{1,2,3}, Georg Oeltzschner^{2,3}, Michael Schär³, Peter Barker^{2,3}, and Richard Edden^{2,3}

¹Biomedical Engineering, Johns Hopkins School of Medicine, Baltimore, MD, United States, ²F. M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD, United States, ³Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins School of Medicine, Baltimore, MD, United States

A new approach for simultaneous dual-voxel J-difference spectral editing is described, that uses spatially selective spectral-editing pulses and Hadamard encoding. The theoretical framework for Spatial Hadamard Editing and Reconstruction for Parallel Acquisition (SHERPA) was developed, applying gradient pulses during the frequency selective editing pulses. SHERPA was simulated for GABA, tested in a two-compartment GABA phantom, and applied to the left and right hemispheres of ten normal subjects. SHERPA was successfully implemented with results in close agreement with conventional MEGA-PRESS scans. Compared to conventional single-voxel single-metabolite J-difference editing, two-fold acceleration is possible without significant loss of SNR using the SHERPA method.

Computer 93

A Vendor-Agnostic MRSI Acquisition and Reconstruction XML Descriptor Format

Marram P Olson¹, Jason C Crane¹, Peder Larson¹, and Sarah J Nelson¹

¹Radiology and Biomedical Imaging, UCSF, San Francisco, CA, United States

The evaluation of MRSI data is complex because data files are encoded with vendor specific file formats and there is a lack of standardized tools for reconstruction. A standard way to describe raw MRSI data is necessary for the reconstruction of sequences utilizing parallel and non-Cartesian sampling strategies. In this work we are developing a vendor neutral data format to define MRSI sequences with arbitrary k-space trajectories that can be used by reconstruction software to understand the data acquisition scheme. This file format is XML-based and uses the ISMRMRD header as a basis for its scheme.

Assessment of Neurochemical changes in HIV adults Using Accelerated MR Spectroscopic Imaging and Compressed Sensing Reconstruction

Rajakumar Nagarajan^{1,2}, Eric S Daar³, Ebrahim Haroon⁴, Zohaib Iqbal², Neil Wilson², Sathya Arumugam², Mario Guerrero³, and Michael A Thomas²

¹Human Magnetic Resonance Center, Institute for Applied Life Sciences (IALS), University of Massachusetts, Amherst, MA, United States, ²Radiological Sciences, University of California Los Angeles, Los Angeles, Los Angeles, CA, United States, ³Medicine, Harbor-UCLA Medical Center, Torrance, CA, United States, ⁴Psychiatry and Behavioral Sciences, Emory School of Medicine, GA, United States

In this work, we have successfully evaluated the accelerated 5D EP-JRESI sequence in 16 adult HIV-infected patients and 15 healthy subjects. Compared to healthy subjects, significant neurochemical changes were observed in HIV+ patients on ART: elevated Ch/Cr ratios in frontal gray, right frontal white and right basal ganglia locations, decreased Glx ratios in the left frontal white, right basal ganglia, occipital gray and white and right insular cortical regions. There was also decreased NAA/Cr in the left basal ganglia and right occipital white regions. In the HIV+ patients, a positive correlation was recorded between the left basal ganglia NAA/Cr and the number of years of ART treatment ($r=0.58$, $p<0.02$).

Low-field cardiac MRI for cardiac radiosurgery using an integrated MRI-guided radiotherapy system

H Michael Gach¹, Roger Nana², Clifford G Robinson³, Philip S Cuculich⁴, Rojano Kashani³, Jeffrey D Bradley³, Michael C Roach³, James F Dempsey⁶, Sasa Mutic³, and Olga Green³

¹Radiation Oncology and Radiology, Washington University in St Louis, St Louis, MO, United States, ²ViewRay, Oakwood Village, OH, United States, ³Radiation Oncology, Washington University in St Louis, St Louis, MO, United States, ⁴Cardiovascular, Washington University in St Louis, St Louis, MO, United States, ⁵ViewRay, Mountain View, CA, United States

Integrated MRI-guided radiotherapy (MRIgRT) systems perform simultaneous MRI acquisitions during radiation therapy to optimize the accuracy of dose delivery. Cardiac radiosurgery using stereotactic body radiation therapy (SBRT) is a promising new treatment option for cardiac arrhythmias. We imaged the heart with a novel ungated radial TrueFISP sequence on a 0.35 T MRIgRT system. The sequence is being developed for next generation SBRT. Image artifacts associated with the sequence were measured using a Medtronic implantable cardiac defibrillator (ICD) in hydrogel and extended 13 cm from its center. Thus, artifacts should not preclude MRIgRT for most patients with ICDs.

Interventional MRI at 3T: Compressed Sensing SEMAC for Improved Needle Visualization

Jan Fritz¹, Wesley D Gilson², Christoph Forman³, Esther Rathel³, Mathias Nittka³, and Allan Belzberg¹

¹The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²Siemens Healthcare USA, ³Siemens Healthcare GmbH

Interventional MR imaging at 3 Tesla benefits from high signal and affords visualization and subsequent targeting of submillimeter structures, but needle artifacts may be exaggerated. Optimized fast gradient echo- and turbo spin echo-based pulse sequences minimize in-plane signal displacement, but through-plane artifacts remain. Compressed Sensing Slice-Encoding Metal Artifact Correction (SEMAC) MRI has the ability to minimize through-plane displacement, and thus holds promise to improve the accuracy of device localization. We demonstrate the clinical feasibility of Compressed Sensing SEMAC TSE for interventional MR imaging at 3 Tesla and visualization of the needle artifact with high accuracy.

Unseen Clinically Significant Prostate Cancer on 3T Multiparametric MRI Challenging Screening and Focal Therapy: An In-bore MRI-Guided Biopsy Study of MRI Negative Areas

Kareem K Elfatairy¹, Christopher P Filson², Omer G Kucuk³, Peter J Rossi⁴, Viraj A Master², and Sherif G Nour¹

¹Radiology, Emory University-School of Medicine, Atlanta, GA, United States, ²Urology, Emory University-School of Medicine, Atlanta, GA, United States, ³Hematology-Oncology and Urology, Emory University-School of Medicine, Atlanta, GA, United States, ⁴Radiation Oncology, Emory University-School of Medicine, Atlanta, GA, United States

The use of multiparametric MRI for prostate cancer screening is challenged by the potential missing of clinically significant cancer in areas with no visible abnormalities. We randomly biopsied areas with no visible targets under direct MRI guidance. Out of 43 biopsied areas, negative predictive value for clinically significant cancers was 90.7% suggesting a very low potential for harboring clinically significant cancers and supporting the use of mpMRI in cancer screening and active surveillance. An extended biopsy approach including sampling of areas without visible MRI abnormalities may still need to be considered prior to focal therapy.

5543

Computer 7

The role of in-bore MR-guided prostate biopsies in patients With discrepancy between MRI findings and TRUS biopsies

Inline Adaptive Spiral Off-Resonance Correction for MRI-guided interventions

Matthew Restivo¹, Michael Hansen¹, Hui Xue¹, and Adrienne Campbell-Washburn¹

¹Biochemistry and Biophysics Center, Division of Intramural Research, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD, United States

Spiral imaging is appealing for MRI-guided interventions due to the need for high frame rate dynamic imaging and low RF power sequences to reduce RF-induced heating in metallic guidewires. Unfortunately, spiral images are susceptible to image distortions due to off-resonance which must be corrected. In this work, we implement a real-time interactive spiral sequence and a fast reconstruction in the Gadgetron that performs inline off-resonance correction that adapts to slice position and orientation changes. We show the effectiveness of our correction in both phantom and in-vivo volunteer images with reconstruction times that are approaching real-time.

Advanced Passive Tracking and Visualization of MR-Compatible Diagnostic Electrophysiology Catheter

Sébastien Roujol¹, Radhouene Neji^{1,2}, Henry Chubb¹, John Silberbauer¹, Tom Lloyd³, Thomas Pohl⁴, Rainer Schneider⁴, Nick Kampa³, James Harrison¹, Steven Williams¹, Rahul Mukherjee¹, Louisa O'Neill¹, John Whitaker¹, Matthew Wright¹, Tobias Schaeffter¹, Mark O'Neill¹, and Reza Razavi¹

¹Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, ²MR Research Collaborations, Siemens Healthcare Limited, Frimley, United Kingdom, ³Imricor Medical Systems, Burnsville, MN, United States, ⁴Siemens Healthcare GmbH, Erlangen, Germany

MRI shows promise for the guidance of electrophysiology (EP) procedures. MR-guided EP procedures require reliable catheter tracking capabilities. Passive catheter tracking enable positive or negative contrast visualization of the catheter in the MR-images using for example integrated ferromagnetic/paramagnetic materials or contrast agent. Positive contrast visualization remains challenging and often sensitive to imaging/post-processing parameters. Negative contrast techniques remain associated with confounding factors (i.e. any other signal void) which complicate visual catheter tracking. In this study, we sought to develop and evaluate a novel framework for passive catheter tracking with negative contrast combined with automatic tracking and enhanced visualization of the catheter.

5547

Simultaneous MR imaging and control of an MR compatible afterloader: feasibility of real-time HDR brachytherapy source tracking

Ellis Beld¹, Marinus A. Moerland¹, Jeroen Schuurman², Frank Zijlstra³, Max A. Viergever³, Jan J.W. Lagendijk¹, and Peter R. Seevinck³

¹Department of Radiotherapy, UMC Utrecht, Utrecht, Netherlands, ²Elekta NL, Veenendaal, Netherlands, ³Image Sciences Institute, UMC Utrecht, Utrecht, Netherlands

For MR-guided high-dose-rate (HDR) brachytherapy, an MR-compatible afterloader was developed, required for real-time HDR brachytherapy source tracking. This afterloader should be able to function well close to the MRI scanner. The functioning of both the MR-compatible afterloader and the MRI scanner, while operating simultaneously, was investigated. Source localization was performed by a phase-only cross correlation localization method. The results demonstrate that the afterloader was able to send the source to predefined source positions, while simultaneously performing MR imaging. Combined with high-temporal resolution imaging and fast reconstruction/post-processing, this study shows the feasibility of real-time source tracking for MR-guided HDR brachytherapy.

5548

MRI-compatible Voltage Device Tracking (VDT) navigation: Simultaneous Tracking and imaging with high-gradient-duty-cycle sequences via complete removal of Gradient Induced Voltages. Initial results.

Mikayel Dabaghyan¹, Jose de Arcos², Raymond Kwong³, William Stevenson³, Jeff Schweitzer⁴, Greg Olson⁴, and Ehud Schmidt²

¹Mirtech, Inc, Brockton, MA, United States, ²Radiology, Brigham and Women's Hospital, Boston, MA, United States, ³Cardiology, Brigham and Women's Hospital, Boston, MA, United States, ⁴St. Jude Medical, Minnetonka, MI, United States

Voltage Device Tracking (VDT), a method for catheter navigation, during MRI is explored. VDT utilizes multiple catheter electrodes that measure both the spatial location of the electrode and the ECG on the vessel wall (EGM) at that location. Electrode spatial-localization is performed by driving intermittent sinusoidal signals at kHz frequencies between surface electrodes, and measuring the signals received by the catheter. Large (>1V) signals (GIV), generated within the body by the MR gradients during a scan interfere with the much smaller (~10mV) tracking signals. We applied two approaches to remove GIVs, which allowed VDT visualization with <5% GIV contamination.

Computer 17

Investigation of Phase-only Cross Correlation (POCC) for Passive Marker Tracking with a limited Number of Projections

Andreas Reichert¹, Axel Joachim Krafft¹, and Michael Bock¹

¹Dept. of Radiology, Medical Physics, Medical Center – University of Freiburg, Freiburg, Germany

In MR-guided interventions passive markers serve as needle guides for percutaneous biopsies and can be followed automatically to visualize the planned needle trajectory. This is achieved by tracking techniques which acquire two cross-sectional Cartesian tracking images of a cylindrical marker to determine the position information. We show that the implementation of radially undersampled tracking images might be used to reduce the duration of percutaneous needle procedures by about 80%.

Computer 18

'Pulse-acquire' method for obtaining the guidewire coupling modes of a PTx transmit array
Felipe Godínez¹, Joseph Hajnal¹, Greig Scott², Ronald Mooiweer¹, and Shaihan Malik¹

¹Imaging and Biomedical Engineering, King's College London, London, United Kingdom, ²Electrical Engineering, Stanford University, United States

A method for measuring relative coupling between elements of a parallel transmit (PTx) array and conductive structures such as guidewires or braided catheters. The method relies on strong local enhancement of B1 fields close to conductors due to induced currents. Data acquired from single pulse-acquire measurements using very low flip angles is hence dominated by these induced current contributions. Coupling matrices for N-channel arrays can therefore be estimated using only N pulses; it is demonstrated that these are similar to those obtained from dedicated current sensors.

Clinical evaluation of automatic localization of prostate gold Fiducial Markers for MR-only Radiotherapy

Matteo Maspero¹, Cornelis AT van den Berg¹, Frank Zijlstra¹, Hans C de Boer^{1,2}, Gert J Meijer^{1,2}, Max A Viergever¹, Jan JW Lagendijk^{1,2}, Linda GW Kerkmeijer^{1,2}, and Peter R Seevinck¹

¹Center for Image Sciences, UMC Utrecht, Utrecht, Netherlands, ²Cancer Center, UMC Utrecht, Utrecht, Netherlands

A novel approach aiming at automatic localization of gold Fiducial Markers (FMs) used in prostate radiotherapy to accurately perform patient positioning is presented and evaluated. The proposed method correctly detected 49/51 FMs in 17 patients when compared to FMs locations manually detected on MR. The spatial accuracy (median) and precision (STD) achieved were 0.2 mm, and 1.2 mm, respectively, when compared to relative FMs locations obtained with CT. When combined with a manual check, this approach could be a safe way to eliminate CT during radiotherapy planning, facilitating an MR-only workflow.

Quantitative Image Analysis of Real-Time Golden Angle Radial iSSFP for Interventional MRI

Samantha Mikaeli^{1,2}, Thomas Martin^{1,2}, Kyunghyun Sung^{1,2,3}, and Holden H Wu^{1,2,3}

¹Radiological Sciences, University of California Los Angeles, Los Angeles, CA, United States, ²Biomedical Physics, University of California Los Angeles, Los Angeles, CA, United States, ³Bioengineering, University of California Los Angeles, Los Angeles, CA, United States

Real-time visualization is crucial to the success of MRI-guided minimally invasive cancer interventions. We have developed golden-angle (GA) ordered radial integrated-SSFP (iSSFP), which can suppress banding artifacts associated with bSSFP while maintaining similar T₂/T₁ contrast. In this work, we further analyze the tissue contrast as well as passive visualization of interventional needles using GA radial iSSFP. In volunteer scans, we verify that GA radial iSSFP achieves T₂/T₁ tissue contrast similar to bSSFP while suppressing banding artifacts. With phantom scans we show that iSSFP reduced the size of the needle-induced signal void, versus that seen on bSSFP. These advantages of GA Radial iSSFP show its potential for improving real-time MRI-guided interventions.

Computer 21

Hydrostatically Actuated MRI-Compatible Motion Platform for Dynamic MRI Research

Samantha Mikaeli^{1,2}, James Simonelli³, Yu-Hsiu Lee³, Xinzhou Li^{1,4}, Kyunghyun Sung^{1,2,4}, Tsu-Chin Tsao³, and Holden H Wu^{1,2,4}

¹Radiological Sciences, University of California Los Angeles, Los Angeles, CA, United States, ²Biomedical Physics, University of California Los Angeles, Los Angeles, CA, United States, ³Mechanical and Aerospace Engineering, University of California Los Angeles, Los Angeles, CA, United States, ⁴Bioengineering, University of California Los Angeles, Los Angeles, CA, United States

Motion is one of the main challenges in MRI, including interventional MRI. While many dynamic imaging and motion compensation techniques have been created, comparisons and validation are difficult, since it is difficult to reproduce in vivo motion for multiple experiments. This work proposes the design and development of a 1 Degree-of-Freedom hydrostatically actuated MRI-compatible motion platform, which can reliably reproduce programmed motion for dynamic MRI experiments.

Motion-corrected high-resolution intra-cardiac imaging using MR-Tracking coils: reducing the effect of noise on motion estimation

Jose de Arcos¹, Mikayel Dabaghyan¹, William G Stevenson², Junichi Tokuda¹, Raymond Y Kwong², Ravi T Seethmaraju³, Jeff Schweitzer⁴, and Ehud J Schmidt¹

¹Radiology, Brigham and Women's Hospital, Boston, MA, United States, ²Cardiology, Brigham and Women's Hospital, Boston, MA, United States, ³Siemens Healthcare, Boston, MA, United States, ⁴St. Jude Medical, Minnesota, MN, United States

We developed an intra-cardiac MRI (ICMRI) catheter to monitor heating during MRI-guided electro-physiological ablative procedures. ICMRI includes an imaging coil that expands within the cardiac chambers and a tetrahedral-shaped array of MR-tracking coils, intended to compensate for cardiac motion during the imaging process. In this study, we used real swine cardiac MR-tracking data, which may contain varying levels of positional uncertainty (noise), to develop algorithms that filter this noise, and thus do not distort the motional (translational/rotational) estimates, required for delivering non-blurred high-resolution intra-cardiac images. Our results show that submillimeter-error motion reconstruction is feasible under realistic levels of noise.

Feasibility study for implementing low-field MRI with SPIO nanoparticles for endovascular interventions – An alternative to X-ray guided techniques

Jordy K. van Zandwijk^{1,2}, Frank F.J. Simonis¹, Robert H. Geelkerken^{1,2}, Robert Meerwaldt², Friso G. Heslinga¹, and Bennie ten Haken¹

¹Faculty of Science and Technology, University of Twente, Enschede, Netherlands, ²Vascular Surgery, Medisch Spectrum Twente, Enschede, Netherlands

Low-field magnetic resonance imaging (lf-MRI) using super-paramagnetic iron-oxide (SPIO) nanoparticles as contrast agent seems to be a promising radiation free alternative to guide endovascular interventions in patients with critical limb ischemia (CLI). We propose an innovative workflow on how to deploy lf-MRI during such an intervention and investigate in phantoms the achievable contrast and resolution levels. The results showed that this combination of lf-MRI with SPIO contrast has potential to guide endovascular interventions, but that high quality pre-operative imaging might be required in deployment of this technique.

Of Active Catheters and Guidewires: How do Guidewires affect the Tracking Signal Intensity?

Thomas Lotzner¹, Ali Caglar Özen¹, Simon Reiss¹, Timo Heidt², Axel J. Krafft¹, Lisa C. Besch², Klaus Düring³, Constantin von zur Mühlen², and Michael Bock¹

¹Dept. of Radiology, Medical Physics, Medical Center - University of Freiburg, Freiburg, Germany, ²Department of Cardiology and Angiology I, University Heart Center, Freiburg, Germany, ³MaRVIS, Frechen, Germany

Active tracking or profiling coils mounted on catheters provide high signal. Other devices in the vicinity can alter the signal acquired by the catheters. The effects of guidewires on the signal from actively tracked catheters were investigated in phantom and in vivo. A standard metallic guidewire and a MR safe guidewire with a passive marker were introduced through the catheter and tested for different positions at the tip. The signal loss was substantial for both guidewires. When the metallic guidewire passed through the catheter tip, the signal was unstable, whereas the MR safe guidewire did not cause any distortions.

Contrast Deposition Within the Dentate Nucleus After Repetitive Administration: Comparison of Linear versus Macrocyclic Gadolinium Contrast Agents

Eugene Huo¹, Bing Tian¹, David Saloner¹, Michael Hope¹, Christopher Hess¹, William Dillon¹, and Thomas Hope¹

¹Department of Radiology & Biomedical Imaging, University of California, San Francisco, San Francisco, CA, United States

Although gadolinium deposition in nephrogenic systemic fibrosis is limited to patients with abnormal renal function, more recent rat and human studies have demonstrated gadolinium deposition in specific brain structures in subjects without renal failure. We report here one of the largest studies evaluating gadolinium deposition in terms of both number of patients and number of doses, verifying the impact of the structural differences between the two most commonly used classes of agents (linear vs macrocyclic) and demonstrating a previously undescribed plateau in signal intensity ratio increase in patients who have received more than 25 administrations of gadolinium.

5562

Computer 98

Gadolinium Containing Metabolites in Brain Tissue. A Study in Rats

Thomas Frenzel¹, Gregor Jost¹, Chirag Apte², and Hubertus Pietsch¹

¹Bayer AG, Berlin, Germany, ²University of British Columbia, Vancouver, BC, Canada

After the repeated dosing of linear or macrocyclic GBCAs in rats, the brain was fractionated 3 and 24d p.i. Cerebrum, cerebellum and pons were separated, homogenized and divided into an insoluble and soluble fraction, which was separated into low and high molecular weight molecules. The gadolinium concentration in the brain was very low. A large portion of the Gd in the linear GBCA groups was found in the insoluble fraction and a smaller portion in large macromolecules. The Gd in the macrocyclic GBCA groups was only found in the soluble fraction and in small molecules. Gd excretion was still ongoing.

5563

In vivo measurements of gadolinium accumulation in bone of healthy individuals following administration of gadolinium-based contrast agents: a pilot study

Michelle L. Lord¹, Fiona E. McNeill², James L. Gräfe³, Michael D. Noseworthy^{4,5}, and David R. Chettle²

¹Radiation Sciences Graduate Program, McMaster University, Hamilton, ON, Canada, ²Department of Physics and Astronomy, McMaster University, Hamilton, ON, Canada, ³Department of Physics, Ryerson University, Toronto, ON, Canada, ⁴McMaster School of Biomedical Engineering, McMaster University, Hamilton, ON, Canada, ⁵Department of Electrical and Computer Engineering, McMaster University, Hamilton, ON, Canada

The use of gadolinium (Gd) based contrast agents is being questioned due to its recently discovered retention in healthy individuals following administration. Our newest generation x-ray fluorescence system has been used in a small pilot study for in vivo Gd measurements in bones of healthy individuals, who have previously received these contrast agents. Preliminary results show a significant difference between the Gd-exposed and control groups, suggesting Gd accumulation in healthy individuals. Our system has performed the first human in vivo measurement of Gd in bone and has the potential to be used in further studies of accumulation in the body.

Computer 100 [Characterization of Gadolinium Deposition in the Brain Manifest as T2-hypointensity and T1-hyperintensity Associated with Repeat Monthly Triple-Dose Gadopentetate Dimeglumine Administration for 2 years in the BECOME Trial](#)

Paul Allen DiCamillo^{1,2}, Michael Benjamin Shvarts^{1,2}, Ravi Bhasker Patel^{2,3,4}, Jhimli Mitra³, Pallavi Tiwari³, Stuart D Cook⁵, Diego Cadavid⁵, Robert T Naismith⁶, Samantha Lancia⁶, and Leo J Wolansky^{1,2}

We characterize the brain parenchymal deposition of Gadolinium (Gd) in the dentate nucleus (DN) and globus pallidus (GP) in a cohort of 16 subjects with multiple sclerosis (MS), each of whom had systematically received one year of serial monthly triple dose Gd (3-dose Gd) and optional additional monthly exposure for a second year. Progressive increase in T1 signal and decrease in T2 signal is found in both the dentate nucleus and globus pallidus.

Computer 101 [SKIN ENHANCEMENT WITH GADOLINIUM BASED CONTRAST AGENTS](#)

Akira YAMAMOTO¹, Tsutomu OKADA¹, Yasutaka FUSHIMI¹, Tomohisa OKADA², and Kaori TOGASHI¹

¹Department of Diagnostic Imaging and Nuclear Medicine, Kyoto University Graduate School of Medicine, Kyoto, Japan, ²Human Brain Research Center, Graduate School of Medicine, Kyoto University, Kyoto, Japan

Skin tissue showed enhancement after GBCA administration. This phenomenon was confirmed by profile curve analysis. Subtraction image between pre-post contrast was calculated after image registration. This subtraction image showed distinct contrast effect of the skin tissue and may be helpful for the clinical diagnosis.

Computer 102 [Comparison of Gd-DTPA-BMA versus Gd-DOTA of Gadolinium retention in human bone tissue with renal function](#)

Takaki Maeda¹, Hitomi Hara², Toshihiro Akisue², Yuki Iwama³, Ryosuke Kuroda², Masahiko Fujii⁴, and Kazuro Sugimura⁵

¹Radiology, Kobe University Hospital, Kobe, Japan, ²Orthopedic Surgery, Kobe University Graduate School of Medicine, ³Radiology, Hyogo Prefectural Nishinomiya Hospital, ⁴Kobe Minimally Invasive Cancer Center, ⁵Kobe University Graduate School of Medicine

The purpose of this study was to determine the gadolinium (Gd) retention in human bone tissue after administration of Gd contrast agent such as macrocyclic (Gd-DOTA) or linear (Gd-DTPA-BMA) chelate at a standard single clinical dose and to evaluate its correlation with renal function.

Computer 103 [Gadolinium presence in the brain: Detection and quantification of gadolinium based contrast agents in the cerebrospinal fluid in rats](#)

Gregor Jost¹, Thomas Frenzel¹, Jessica Lohrke¹, Diana Lenhard², Shinji Naganawa³, and Hubertus Pietsch¹

¹MR & CT Contrast Media Research, Bayer Pharma AG, Berlin, Germany, ²Institute of Vegetative Physiology, Charité, Berlin, Germany, ³Department of Radiology, Nagoya University Graduate School of Medicine, Nagoya, Japan

The infiltration of six marketed and one experimental gadolinium based contrast agents (GBCA) from blood into the cerebrospinal fluid (CSF) was evaluated in rats by repeated fluid attenuated (FLAIR) MRI up to 4h. Quantitative gadolinium measurements in CSF samples (4.5 and 24h) were performed by ICP-MS. No differences in penetration and distribution into the CSF were observed for the marketed GBCAs. FLAIR imaging demonstrates a kinetic from the inner CSF cavities to the subarachnoid space, suggesting an infiltration via the choroid plexus and a passive distribution with CSF flow. After 24h an almost complete GBCA clearance from CSF was observed.

Computer 104 [A Manganese-Based Alternative to Gadolinium: Contrast Enhanced MR Angiography at 3T and In Vivo Stability](#)

Eric M Gale¹, Hsiao-Ying Wey¹, Ian Ramsay¹, David E Sosnovik¹, and Peter Caravan¹

¹A. A. Martinos Center for Biomedical Imaging, MGH/ Harvard Medical School, Charlestown, MA, United States

We evaluated the efficacy of a new manganese-based contrast agent, Mn-PyC3A, in contrast-enhanced MR angiography by comparison to Gd-DTPA in a baboon model at 3T. Mn-PyC3A clearance was assessed by dynamically scanning the excretory organs and performing serial blood draws out to 60 min. Mn-PyC3A plasma clearance and metabolism were quantified from the drawn blood. Mn-PyC3A generates equivalent vessel-to-muscle contrast-to-noise ratios as Gd-DTPA at 3T, clears via a mixed renal and hepatobiliary pathway, and is excreted unchanged. Mn-PyC3A is a functionally equivalent gadolinium-free alternative for contrast-enhanced MRI angiography.

Computer 105 [Ferumoxytol as an Alternative to Gadolinium-based MRI Applications in Patients With and Without Renal Impairment: Acute and Short-term Safety Experience](#)

Kim-Lien Nguyen^{1,2}, Takegawa Yoshida^{1,3}, Isidro B Salusky⁴, Peng Hu^{1,3}, and J. Paul Finn^{1,3}

¹Diagnostic Cardiovascular Imaging Laboratory, David Geffen School of Medicine at UCLA, Los Angeles, CA, United States, ²Division of Cardiology, David Geffen School of Medicine at UCLA and VA Greater Los Angeles Healthcare System, Los Angeles, CA, United States, ³Department of Radiological Sciences, David Geffen School of Medicine at UCLA, ⁴Department of Pediatric Nephrology, David Geffen School of Medicine at UCLA

Recent concerns about gadolinium deposition in biologic tissues and discontinuation of gadofosveset trisodium have created increased interest in the off-label use of ferumoxytol as an MRI contrast agent. Limited safety data relating to the diagnostic use of ferumoxytol are available. We summarize our safety experience with ferumoxytol as an alternative MRI contrast agent in 285 unique patients (314 injections) with all levels of renal function.

Immediate Reactions to Gadolinium Based Contrast Agents: a Meta-Analysis

Ashkan Heshmatzadeh Behzadi¹, Yize Zhao², Zerwa Farooq³, and Martin R. Prince⁴

¹Radiology, Weill Cornell Medical College, New York, NY, United States, ²Department of Healthcare Policy and Research, Weill Cornell Medical College, New York, ³Radiology, Weill Cornell Medical Center, ⁴Department of Radiology, Cornell and Columbia Universities, New York, NY, United States

Recently there has been increased attention focused on GBCA safety and data on the numbers of reactions have begun to be reported in large Studies. Here we combine data from multiple papers in a meta-analysis to determine if certain GBCA or classes of GBCA may have different immediate reaction profiles.

5571

Computer 107

Impact of renal impairment on T1-weighted signal increase and gadolinium presence in the rat brain after multiple administrations of gadolinium based contrast agents

Hubertus Pietsch¹, Thomas Frenzel¹, Jessica Lohrke¹, and Gregor Jost¹

¹MR & CT Contrast Media Research, Bayer Pharma AG, Berlin, Germany

The impact of renal insufficiency on the T1-weighted signal intensity (SI) increase in the cerebellar nuclei (CN) and on the brain gadolinium concentration was evaluated by comparing 5/6-nephrectomized to healthy control rats. Eight weeks after repeated high-dose GBCA administrations a significantly higher CN/pons SI ratio compared to a saline control group was found for linear GBCAs. This was independent of the renal status. No altered SI ratios compared to the saline group were observed after administration of macrocyclic GBCAs. Inductive coupled plasma mass spectrometry revealed higher gadolinium concentrations for all GBCAs in the cerebellum of renally impaired rats.

5572

T1-signal increases as a marker of Gd-deposition in pediatric brain: findings after multiple exposures to gadobenate dimeglumine

Guenther Schneider¹, Paul Raczeck¹, Arno Buecker¹, and Jonas Stroeder¹

¹Saarland University Medical Center, Homburg, Germany

The possibility of Gd deposition in the pediatric brain following exposure to GBCAs is a potentially serious issue. Our study of 34 pediatric patients that received between 5 and 15 administrations of low dose (0.05 mmol/kg bodyweight) gadobenate dimeglumine (MultiHance; Bracco) revealed no differences in T1-signal in the DN, GP, pons and thalamus relative to measurements made in 24 age- and weight-matched control subjects that had never been exposed to any GBCA. Likewise no meaningful differences were seen in DN-pons and GP-thalamus SI ratios. We consider low dose gadobenate to be safe and effective for diagnosis and routine follow-up of pediatric oncologic patients.

5573

Computer 109

Strong enhancement of relaxivity of gadolinium contrast agent in solution with intracellular viscosity: Quantitative estimation of the deposited contrast agent in the brain

Ken Masuyama^{1,2}, Masayuki Taguchi¹, and Toru Yamamoto³

¹Graduate School of Health Sciences, Hokkaido University, Sapporo, Japan, ²Department of Medical Radiation Technology, Teine Keijinkai Hospital, Sapporo, Japan, ³Faculty of Health Sciences, Hokkaido University, Sapporo, Japan

High T1-weighted signal appears in brain of patients who have experienced MRI examinations using gadolinium contrast agent several times. The relaxation effect of gadolinium contrast agent strongly depends on the viscosity of the solution, and the average viscosity in the cell is higher than that of the free water. However, the relaxation effect of the gadolinium contrast agent in the cell has been unknown. In this study, we investigated the longitudinal relaxivity of it – concentration dependence of longitudinal relaxation rate in solution with intracellular viscosity. The intracellular viscosity strongly enhances the longitudinal relaxivity of the gadolinium contrast agent.

Computer 113

RF safety assessment of a 32-channel integrated body coil for 7 Tesla: Thermal dose evaluation at high SAR level

Thomas M. Fiedler¹, Stephan Orzada², Martina Flöser¹, Harald H. Quick^{2,3}, Mark E. Ladd^{1,2}, and Andreas K. Bitz¹

¹Medical Physics in Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany, ²Erwin L. Hahn Institute for MRI, University Duisburg-Essen, Essen, Germany, ³High Field and Hybrid MR Imaging, University Hospital Essen, Essen, Germany

RF safety assessment for a 32-ch body coil for 7T was performed based on SAR, tissue temperature, and a thermal dose model (CEM43°C). Temperature simulations considered a temperature-dependent thermoregulation. The tissue temperature limit is exceeded when SAR limits are adhered to. However, based on the thermal dose limit, the maximum input power determined from SAR limits can be exceeded by up to a factor of 5 without noticeable limitations in permissible exposure time in MR examinations. This increased input power allows for improved B₁⁺ homogeneity with 50% reduced flip angle error compared to the input power determined from SAR limits.

5578

Computer 114

The effect of variable amniotic fluid conductivity and fetal tissues properties on B₁⁺ and local SAR for fetal imaging at 3T

Shaihan J Malik¹, Jeffrey W Hand¹, and Joseph V Hajnal¹

¹Division of Imaging Sciences & Biomedical Engineering, King's College London, London, United Kingdom

Effects on B₁⁺ and local specific absorption rate of varying the conductivity of fetal tissues and amniotic fluid (σ_{AF}) in a model of a 7 month pregnant woman within a 3T birdcage coil are investigated numerically. Results indicate that a realistic value of σ_{AF} is required to estimate power to produce a chosen B₁⁺ in the fetus and fetal SAR_{10g}. Fetal properties adjusted for gestational age impact on B₁⁺ and result in increased fetal SAR_{10g} compared to adult value based simulations. Smaller changes in SAR_{10g} are predicted between detailed fetal models and homogeneous ones with volume weighted average dielectric properties.

5579

Evaluation of SMS sequence on the AIMD MRI model validation
Yuliang Du¹, Xi Lin Chen², Will Lui², Shi Feng², and Shiloh Sison²

¹CRMD-Hardware Development, St Jude Medical, Sylmar, CA, United States, ²St. Jude Medical

Impacts of SMS imaging technique on the AIMD design, transfer function measurement, model calculation and system validation were thoroughly analyzed. The RF frequency broadening from the SMS imaging sequence has minimal impacts to the existing device design and test methodology.

5583

Computer 119

Graphene for MRI Applications at 7T: Opportunities for SAR reduction

Gianluigi Tiberi^{1,2}, Guo Liu³, Raj Mittra⁴, and Michela Tosetti^{1,2}

¹Imago7, Pisa, Italy, ²IRCCS Stella Maris Foundation, Pisa, Italy, ³Xidian University, Xidian, People's Republic of China, ⁴University of Central Florida in Orlando, Orlando, FL

SAR management is critical at ultra-high field (UHF) strength where RF field energy deposition in the subject increases and its distribution becomes very inhomogeneous. Here we illustrate simulation results for a test example in order to show how a graphene sheet can be used to obtain a SAR reduction without sacrificing the coil efficiency significantly. Specifically, the presence of the graphene sheet leads a maximum local SAR reduction up to 47%. Thus, from the simulation here shown, it follows that graphene sheets can be successfully used in MRI applications at 7T for enhancing the safety with respect to SAR issue

5584

Computer 120

Safety and Function of Programmable Ventriculo-Peritoneal Shunt Valves: An in vitro 7 Tesla Magnetic Resonance Imaging Study

Karsten H Wrede^{1,2}, Bixia Chen^{1,2}, Ulrich Sure², Harald H Quick^{1,3}, and Oliver Kraff¹

¹Erwin L. Hahn Institute for MRI, University of Duisburg-Essen, Essen, Germany, ²Department of Neurosurgery, University Hospital Essen, University of Duisburg-Essen, Essen, Germany, ³High Field and Hybrid MR Imaging, University Hospital Essen, University of Duisburg-Essen, Essen, Germany

This in vitro study tests function, safety and image artifacts of the two worldwide most frequently implanted programmable VP-shunt valves in a 7 Tesla whole body MRI system. Both tested programmable VP-shunt valves lost their ability to be reprogrammed after exposure to the static magnetic field and are therefore unsafe for use in 7 Tesla whole body scanners in their current design. Magnetic coercivity of the permanent magnets in the programming mechanisms was insufficient. Image artifacts adjacent to the valves, however, were tolerable.

A MatLab-based simulation program (tcaSIM₂) for predicting NMR spectra and MS data for ¹³C tracer experiments

A. Dean Sherry^{1,2}, Qiang Li³, Mark Jeffrey³, Shawn Burgess¹, and Craig R. Malloy¹

¹Advanced Imaging Research Center, University of Texas Southwestern Medical Center, Dallas, TX, United States, ²Chemistry, University of Texas at Dallas, Richardson, TX, United States, ³Advanced Imaging Research Center, UT Southwestern Medical Center

A MatLab-based program is presented for predicting ¹³C NMR spectra and mass ¹³C isotopomer data of various tissue metabolites in a ¹³C tracer experiments. The program is useful for predicting changes in ¹³C multiplet patterns in NMR spectra and changes in mass isotopomer ratios in mass spectral data as a tissue responds to changes in flux of various substrates through completing pathways involving mitochondrial metabolism. The program tcaSIM₂ (copies available free of charge) is also valuable for teaching metabolism and analysis of ¹³C NMR data and mass spec data in metabolic tracer experiments.

Use of MR Spectroscopy in Clinical Trials

Alexander Peter Lin¹, Benjamin Rowland¹, and John R Griffiths²

¹Center for Clinical Spectroscopy, Brigham and Women's Hospital, Boston, MA, United States, ²Cancer Research UK Cambridge Institute, University of Cambridge, Cambridge, United Kingdom

Magnetic resonance spectroscopy (MRS) is an ideal tool for therapeutic monitoring in clinical trials although its role has not been formally examined. An initial search in a clinical trials database showed 488 studies; however the results were cross-referenced with the scientific literature to yield 61 studies demonstrating the use of MRS in clinical trials. It is most frequently used to study hepatic lipid content, followed by studies of skeletal muscle, and finally the brain, which surprisingly was only 15% of the MRS studies. A review is provided to assess its importance as a non-invasive and quantitative biomarker for disease.

Computer 28

Effect of liver transplantation on muscle metabolism and the abdomen adipose tissue volume in diabetic and non-diabetic patients

Petr Sedivy¹, Miloslav Drobny¹, Monika Dezortova¹, Irena Hejlova², Monika Cahova³, Pavel Trunecka², and Milan Hajek¹

¹MR-unit, Institute for Clinical and Experimental Medicine, Prague, Czech Republic, ²Hepatogastroenterology Department, Institute for Clinical and Experimental Medicine, Prague, Czech Republic, ³Centre of Experimental Medicine, Institute for Clinical and Experimental Medicine, Prague, Czech Republic

Liver transplantation (TxL) is a treatment that rapidly improves the clinical status of patients. However, side effects due to long-term immunosuppressive therapy may negatively influence the function of certain organs and metabolism. ³¹P MRS and MRI are suitable methods for the clinical examination of muscles and abdomen fat volume in transplanted patients. Our pilot results show that TxL leads to an improvement of resting muscle metabolism in especially in diabetic patients and an increase of volume visceral fat in a short term (six months) after transplantation.

Relationship Between BOLD fMRI and Functional MRS the Medial Temporal Lobe

Simona Nikolova¹, Shauna Stark¹, and Craig E.L. Stark^{1,2}

¹Department of Neurobiology and Behavior, University of California, UCI, Irvine, CA, United States, ²Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA, United States

Structures in the medial temporal lobe (MTL) like the hippocampus play a critical role in memory. Functional disruptions of the MTL (typically studied with BOLD fMRI) are present in a range of disorders and diseases. The relative and indirect nature of BOLD makes it difficult to interpret findings such as the hippocampal "hyperactivity" that has been tied to age-related cognitive decline and the progression to Alzheimer's Disease. In this work, "functional" MR spectroscopy is combined with simultaneous BOLD during memory tasks to investigate the relationship between the two. While task-related activity is observed in both, there are points of departure.

Computer 30

Online quantification of lactate concentration in microdialysate during cerebral activation using ¹H-MRS and sensitive NMR microcoilLeslie Mazuel¹, Ursule Dumont², Noël Pinaud², Vanessa Zhendré², Silvia Rizzitelli², Jory Blanc¹, H  l  ne Roumes¹, Anne-Karine Bouzier-Sore¹, and Yannick Cr  millieux²

¹CRMSB, Universit   de Bordeaux, Bordeaux, France, ²Institut des Sciences Mol  culaires, Universit   de Bordeaux, Bordeaux, France

The role of lactate in neuronal activation is central in the hypothesis of the astrocyte-to-neurons lactate shuttle. In this work, we implement highly sensitive ¹H-MRS on brain microdialysate in order to monitor online the lactate fluctuations during neuronal activation in the S1BF area. The custom-made microcoil used in this study was shown to be sensitive enough for measuring a 40% increase in lactate concentration during brain stimulation.

5591

¹H and ¹³C NMR evaluation of pH-dependent structural characteristics of IonidamineKavindra Nath¹, Jeffrey Roman¹, David S Nelson¹, Andrew Butterworth¹, Stephen Pickup¹, Dennis B Leeper², and Jerry D Glickson¹

¹University of Pennsylvania, Philadelphia, PA, United States, ²Thomas Jefferson University, Philadelphia, PA, United States

We seek to understand the pH-dependent physicochemical changes of Ionidamine (LND), an antineoplastic drug, particularly to locate the sites of ionization. LND samples at pH 2, 7, and 13 were analyzed using ¹H and ¹³C NMR. The results indicate that there is a noticeable change in the chemical shifts for a few atoms in LND from neutral to alkaline pH. These changes demonstrate that LND is ionized at its imidazole α -nitrogen. In addition, the expected ionization of the carboxyl group of LND at acid pH is not directly observed, and this may be due to a rapid-exchange phenomenon.

Characterization of Water Compartment Exchange in Ex-Vivo Human Cartilage Using Two-Dimensional Relaxometry

Kyle William Sexton¹, David A. Reiter¹, Hasan Celik², Kenneth Fishbein¹, Tariq Nayfeh³, and Richard G. Spencer¹

¹Magnetic Resonance Imaging and Spectroscopy Section, National Institute on Aging, Baltimore, MD, United States, ²University of California, Berkeley, CA, United States, ³Medstar Harbor Hospital, Baltimore, MD, United States

One-dimensional transverse relaxometry has proven to be an effective method for characterizing macromolecular compartments in cartilage. Two-dimensional studies extend the capabilities of these types of experiments, providing characterization of tissue compartments in terms of correlated relaxation times and providing a means of probing intercompartmental exchange. We provide results of T_2 - T_2 and T_1 - T_2 relaxometry experiments on human articular cartilage, indicating that exchange between tissue compartments may be augmented in degraded tissue.

5593

Computer 33 Full Digital Cancellation-based NMR with Concurrent Excitation and Acquisition using a Lock-in Amplifier

Ali Caglar Özen¹, Mazin Jouda², Jan Korvink², and Michael Bock¹

¹Department of Radiology, Medical Physics, Medical Center – University of Freiburg, Freiburg, Germany, ²Institute of Microstructure Technology, Karlsruhe Institute of Technology, Karlsruhe, Germany

Concurrent Excitation and Acquisition (CEA) offers fundamental advantages for NMR such as 100% signal acquisition efficiency, true zero echo time, reduction of acoustic noise, and decreased peak RF power. Bandwidth of the excitation in CEA is independent of the RF power, allowing detection very broad resonances. In this work, a CEA system is introduced with a full digital cancellation. The system uses a lock-in amplifier combined with an arbitrary signal generator. Preliminary results for NMR of various samples are represented and discussed.

5594

Computer 34 In vivo brain redox status and blood-brain barrier function in diethylmaleate-treated mice by EPR imaging and ME-MRI

Hirotada G Fujii¹, Miho C Emoto¹, Yuta Matsuo², and Ken-ichi Yamada²

¹Sapporo Medical University, Sapporo, Japan, ²Kyushu University, Fukuoka, Japan

EPR imaging has been used to visualize redox status in oxidative brain diseases, but the role of cerebral glutathione (GSH) is not clear. In this study, using the mouse model of GSH depletion with diethylmaleate (DEM), the role of GSH in brain redox status was examined. The remarkable change in redox status in DEM-treated mouse brain was visualized with EPR imaging, and in vitro assay showed decrease in the level of GSH. ME-MRI clearly visualized blood-brain barrier dysfunction in DEM-treated mice. Results indicate that GSH plays an important role in the maintenance of both brain redox status and BBB integrity.

5595

Computer 35 Unique molecular signatures to distinguish immunotherapy responding and resistant cell lines in melanoma by NMR spectroscopy and MR hyperpolarization

Shivanand Pudukalakatti¹, Ashvin Jaiswal², Prasanta Dutta¹, Michael Curran², and Pratip Bhattacharya¹

¹Department of cancer systems imaging, University of Texas M D Anderson Cancer Center, Houston, TX, United States, ²Department of Immunology, University of Texas M D Anderson Cancer Center, Houston, TX, United States

The cancer immunotherapy has brought new ray of hope in cancer patients with its capability of curing cancer with less side effects. However not all patients responds to therapy. In this study we have employed Nuclear Magnetic Spectroscopy (NMR) and in vivo hyperpolarized 1-13C pyruvate magnetic resonance spectroscopy (MRS) to differentiate immunotherapy responding from immunotherapy resisting melanoma.

5596

Computer 36 Lactate and lipid provide identifying biomarkers for good quality sperm by ¹H MRSSarah J Calvert¹, Steven Reynolds², Martyn N Paley², and Allan A Pacey¹

¹Academic Unit of Reproductive & Developmental Medicine, University of Sheffield, Sheffield, United Kingdom, ²Academic Unit of Radiology, University of Sheffield, Sheffield, United Kingdom

¹H MRS was used to examine good and poor sperm populations to identify biomarker differences between them. Spectra were binned to 0.02ppm and two-way ANOVA with Bonferroni correction, Wilcoxon match rank test and ROC curve analyses were used to find bins with significant differences between good and poor sperm. All three statistical methods identified the bins at 1.24-1.32ppm which correlates with overlapping lipid and lactate peaks. Differences in these peaks may result from metabolic differences between the two sperm populations and this may give a useful insight into the pathology of sperm dysfunction.

5597

Computer 37 Metabolic differences in patients with Overt and Potential Celiac disease Studied by in-vitro Proton NMR

Uma Sharma¹, Deepti Upadhyay¹, Prasenjit Das², Siddhartha Datta Gupta², Govind K Makharia³, and Naranamangalam R Jagannathan¹

¹Nuclear Magnetic Resonance and MRI Facility, All India Institute of Medical Sciences, New Delhi, India, ²Pathology, All India Institute of Medical Sciences, New Delhi, India, ³Gastroenterology & Human Nutrition, All India Institute of Medical Sciences, New Delhi, India

Potential celiac disease (CeD) patients have immunological abnormalities similar to CeD but unlike CeD, their duodenum displays normal histology. In-vitro proton NMR study of small intestinal mucosa of these patients demonstrated metabolic abnormalities associated with the intestinal inflammation. Both potential CeD and CeD patients had lower concentration of histidine compared to controls while lower glycine was seen only in CeD. Since, both amino acids exert anti-inflammatory effects; their reduced levels suggested compromised cytoprotective mechanism. Significantly higher level of glycerophosphocholine seen in potential CeD compared to CeD might have contributed for renewal of enterocytes and thus to normal small intestine histology.

5598

Computer 38 High-resolution MRS characterization of malignant ascites in two different models of ovarian cancer

Santosh K Bharti¹, Flonné Wildes¹, Chien-Fu Hung², TC Wu², Zaver M Bhujwala^{1,3}, and Marie-France Penet^{1,3}

¹JHU ICMIC Program, Division of Cancer Imaging Research, The Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²Pathology, The Johns Hopkins University School of Medicine, ³Sidney Kimmel Comprehensive Cancer Center, The Johns Hopkins University School of Medicine

Malignant ascites occurs in approximately 37% of terminal ovarian cancer patients. It significantly contributes to poor quality of life and mortality. Advances in understanding malignant ascites formation and finding new therapeutic options are urgently needed. High-resolution proton magnetic resonance spectroscopy provides opportunities to characterize biofluid metabolites and can be easily translated to the clinic. Here, we are investigating the metabolic profile of ascites obtained in two different experimental models of ovarian cancer. To further understand the differences observed between both models, we completed our study by analyzing the metabolic profiles of those cells in culture and their corresponding conditioned media.

5599

Computer 39

High-resolution ¹H MRS human plasma profiling of pancreatic ductal adenocarcinoma

Santosh K Bharti¹, Michael Goggins^{2,3}, and Zaver M Bhujwala^{1,3}

¹JHU ICMIC Program, Division of Cancer Imaging Research, The Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²Departments of Pathology and Medicine, The Sol Goldman Pancreatic Cancer Research Center, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ³Sidney Kimmel Comprehensive Cancer Center, The Johns Hopkins University School of Medicine, Baltimore, MD, United States

The dismally poor 5 year survival rate of less than 6% in pancreatic ductal adenocarcinoma (PDAC) increases to ~50% with early stage PDAC making early detection critically important. Metabolic characterization of patient plasma samples provides a unique opportunity to identify biomarkers to assist in routine screening to detect of PDAC. Here, in a preliminary study, we have characterized the metabolic profiles of plasma samples from normal, benign, and PDAC patients. Even with a limited sample we identified a significant increase in β-hydroxybutyrate, acetate, acetoacetate, lactate and pyruvate in PDAC compared to normal plasma.

Interrogating Liver Metabolic Stress due to Cancer-Induced Cachexia

Santosh K Bharti¹, Paul T Winnard Jr.¹, Yelena Mironchik¹, Anirban Maitra², and Zaver M Bhujwala^{1,3}

¹JHU ICMIC Program, Division of Cancer Imaging Research, The Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ²MD Anderson Cancer Center, The University of Texas, Houston, TX, United States, ³Sidney Kimmel Comprehensive Cancer Center, The Johns Hopkins University School of Medicine, Baltimore, United States

Cachexia is a poorly understood metabolic syndrome characterized by cancer-induced tissue wasting and weight loss. Cachexia occurs with the highest frequency and severity in pancreatic ductal adenocarcinoma (PDAC). To further understand this syndrome, here we used ¹H MRS to analyze liver metabolites in mice with and without cachexia-inducing PDAC. We detected profound liver weight loss in cachectic mice. ¹H MR spectra identified significant depletion of lactate, glucose and glutathione in cachectic mice that provide new insights into the syndrome and may present novel strategies to prevent or reduce cachexia-induced weight loss and the morbidity and mortality associated with the syndrome.

Computer 41

Phenformin Induces Profound Metabolic Changes in Lung Cancer Cells

Santosh Kumar Bharti¹, Ellen Tully², Edward Gabrielson², and Zaver M Bhujwala^{3,4}

¹Radiology, JOHNS HOPKINS UNIVERSITY, BALTIMORE, MD, United States, ²Department of Pathology, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ³JHU ICMIC Program, Division of Cancer Imaging Research, The Russell H. Morgan Department of Radiology and Radiological Science, The Johns Hopkins University School of Medicine, Baltimore, MD, United States, ⁴Sidney Kimmel Comprehensive Cancer Center, The Johns Hopkins University School of Medicine, Baltimore, United States

Lung cancer is a leading cause of cancer associated death in United States and worldwide. Non-small cell lung cancer (NSCLC) accounts for 85% of all lung cancer cases in the United States. Use of metformin is associated with improved cancer treatment outcomes, reduction in cancer incidence and decreased mortality, and because of a higher potency, phenformin may be a more promising anti-cancer agent. Here, we have used ¹H MRS of cell extracts to investigate the effect of phenformin on A549 cells. Significant metabolic changes were observed following phenformin treatment

5602

Computer 42

A Very Low-cost EPR Spectrometer Using 3D Design and Manufacturing

Bahareh Behzadnezhad^{1,2}, Jian Dong¹, Nader Behdad¹, and Alan McMillan²

¹Dept of Electrical and Computer Engineering, University of Wisconsin-Madison, Madison, WI, United States, ²Dept of Radiology, University of Wisconsin-Madison, Madison, WI, United States

This study describes a very low-cost EPR spectrometer that can be feasibly constructed using general purpose laboratory equipment combined with the use of 3D electromagnetic design and additive manufacturing. We demonstrate a functioning, homebuilt, low-cost continuous wave EPR spectrometer operating at 115 MHz. The development of a low-cost spectrometer has applications in education and for other general laboratory purposes.

5603

Computer 43

Detection of Tumor Spheroid Metabolism Using Hyperpolarized Magnetic Resonance Spectroscopy

Sui-Seng Tee¹, Izabela Suster¹, Sangmoo Jeong¹, Roozbeh Eskandari¹, Valentina Di Gialleonardo¹, Kristin L Granlund¹, Vesselin Miloushev¹, Steven Truong², and Kayvan Keshari¹

¹Memorial Sloan Kettering Cancer Center, New York, NY, United States, ²Hunter College, New York

Cell-line tumor spheroids or patient-derived organoids are 3D structures that self-organize when grown in a suitable extracellular matrix. As they mirror in vivo physiology and biology well, these structures have been used as surrogates for clinical trials. This study describes the ability to grow spheroids in NMR-compatible scaffolds that metabolize hyperpolarized [1-13C] pyruvate. These spheroids are also sensitive to AKT inhibition that manifest in significantly decreased lactate production. Histological analysis confirms on-target inhibition, demonstrating that hyperpolarized magnetic resonance spectroscopy can be used to probe treatment response in spheroids that can mimic human disease.

Computer 44

Comprehensive Metabolic Profiling of Urosepsis with positive and negative controls

Suruchi Singh¹, Tanushri Chatterji², Manodeep Sen², Ishwar Ram Dhayal³, and Raja Roy¹

¹Centre of Biomedical Research, Lucknow, India, ²Department of Microbiology, Dr. Ram Manohar Lohia Institute of Medical Sciences, Lucknow, India, ³Department of Urology, Dr. Ram Manohar Lohia Institute of Medical Sciences, Lucknow, India

This study presents the metabolic perturbation in serum and urine samples while comparing Urosepsis with negative and positive controls. It explores the metabolic differentiation of serum samples with sepsis and urine samples with urinary tract infection (UTI) (considered as positive controls), and healthy controls (considered as negative controls) respectively. The serum and urine metabolic profile mainly depicted changes occurring due to severity and spread of infection. The statistical Partial Least Square Discriminant Analysis (PLS-DA) model was robust enough to differentiate the three groups distinctively in both serum and urine samples.

Computer 45

Metabolomical NMR measurements of cell cultures: Increasing the metabolic stability of lysed cells by additional heating due to enzymatic inactivation.

Gaëlle Diserens¹, Damian Hertig^{2,3}, Martina Vermathen², Balazs Legeza⁴, Christa E. Flueck⁴, Jean-Marc Nuoffer³, and Peter Vermathen¹

¹Depts. Radiology and Clinical Research, University Bern, Bern, Switzerland, ²Dept. Chemistry and Biochemistry, University Bern, Bern, Switzerland, ³University Institute of Clinical Chemistry, Bern University Hospital, Bern, Switzerland, ⁴Pediatric Endocrinology and Diabetology of the Dept. Pediatrics & Dept. Clinical Research, University Bern, Bern, Switzerland

Advanced NMR measurements of biological samples may take several hours. Preanalytical issues may impact the metabolite content, potentially leading to misinterpretation. Our aim was to investigate by ¹H HR-MAS NMR the impact of different cell handling preparation protocols (lysis with and without heating) on the stability of the cell metabolome over the measurement time. In lysed fibroblasts and adrenal-cells, metabolism was ongoing over-time, contrary to a stable metabolite content of the lysed-heated cells. Therefore, to minimize metabolome modifications over the measurement time, it is suggested to use cell lysis in combination with heat inactivation for extended HR-MAS NMR measurements.

Effect of Coil Proximity on Parallel Spectroscopic Data Collection with Phased Array Coils

Candace C Fleischer¹, Xiaodong Zhong^{1,2}, and Hui Mao¹

¹Department of Radiology and Imaging Sciences, Emory University, Atlanta, GA, United States, ²MR R&D Collaborations, Siemens Healthcare, Atlanta, GA, United States

Parallel imaging and spectroscopy are facilitated by multi-channel phased array coils. An important step is the combination of individual data from each channel, yet the effect of the non-uniformity of array coils on signal-to-noise ratio (SNR) is poorly characterized. Here, we present a systematic framework for identifying vulnerabilities in phased array coils for MRS. We demonstrate the importance of voxel position and coil proximity on overall SNR in a phantom and human subject, with significant SNR improvements after selectively filtering individual spectra based on pre-determined SNR thresholds which must be optimized for each phased array coil and volume of interest.

The feasibility of absolute quantification for ^{31}P MRS at 7TLucian A. B. Purvis¹, Ladislav Valkovic¹, Matthew D. Robson¹, and Christopher T. Rodgers¹¹OCMR, Department of Cardiovascular Medicine, University of Oxford, Oxford, United Kingdom

Calculation of in vivo concentrations requires knowledge of the B_1 field. A common solution to this problem has been to use field maps measured in phantoms, but this becomes increasingly difficult at high field. The size of the effect of material and B_0 field strength determining B_1 in the liver using phosphorus (^{31}P) phantoms was investigated at 1.5, 3, and 7T using CST simulations. The effect of concentration differences at 7T was demonstrated using 15 and 30mM phosphate phantoms. At 1.5T, using phosphate phantoms with concentrations between 5-40mM give an error of less than 3%. This increases to 10% at 3T, and 20-114% at 7T.

5610

Computer 50

Effect of hyperbaric oxygenation on human brain phosphate metabolites at 3 Tesla. In vivo ^{31}P MRS studyAndrei Valerievich Manzhurtsev^{1,2}, Olga Vasyukova³, Victoria Victorovna Sergeeva⁴, Tolibjon Abdullaevich Akhadov², Iliia Andreevich Mel'nikov², Olga Vasil'evna Bozhko², and Natalia Alexandrovna Semenova^{1,2,5}

¹N.M.Emanuel Institute of Biochemical Physics of RAS, Moscow, Russian Federation, ²Radiology, Research Institute for Children Emergency Surgery and Traumatology, Moscow, Russian Federation, ³National Research Nuclear University "MEPhI", Moscow, Russian Federation, ⁴Hyperbaric Oxygenation Dept., Research Institute for Children Emergency Surgery and Traumatology, Moscow, Russian Federation, ⁵N.N. Semenov Institute of Chemical Physics of RAS, Moscow, Russian Federation

This study is aimed to reveal the effects of hyperbaric oxygenation on human brain phosphate metabolites using ^{31}P MRS. At first, ^{31}P MRS study was conducted, after that the subjects took a session in hyperbaric chamber (1.2 atmosphere, 100% O_2) and then ^{31}P MRS study was repeated. The increase of α -ATP peak intensity was revealed after hyperbaric oxygenation, while other peak intensities and pH remained unchanged. This phenomenon is likely to happen because of [NAD(H)] increase, that might confirm the positive effect of hyperbaric oxygenation on human brain metabolism.

5611

Computer 51

31P spectroscopic imaging of the human brain at 3T: effect of NOE and ^1H -decouplingMark J. van Uden¹, Tom H. Peeters¹, Tom W.J. Scheenen¹, and Arend Heerschap¹¹Radiology and Nuclear Medicine, Radboud university medical center, Nijmegen, Netherlands

^{31}P MRS of the brain can reveal changes in energy and lipid metabolism in healthy and diseased brain. In this abstract we compare ^{31}P MRS measurements with and without NOE and/or ^1H -decoupling. Adding nuclear Overhauser enhancement (NOE) and ^1H -decoupling to a ^{31}P MRS measurement at 3T increases spectral resolution to that at 7T and improves sensitivity so that the theoretical difference with 7T is partly compensated for. At relatively short repetition times both ^1H -decoupling and NOE have to be taken into account for proper quantification.

5612

Computer 52

Different activated calf muscle groups measured simultaneously during plantar flexion exercise with multiple knee angles using multivoxel ^{31}P -MRS.Fabian Niess¹, Georg Bernd Fiedler¹, Albrecht Ingo Schmid¹, Sigrun Goluch¹, Roberta Frass-Kriegel¹, Michael Wolzt², Ewald Moser¹, and Martin Meyerspeer¹

¹Center for Medical Physics and Biomedical Engineering, Medical University Vienna, Vienna, Austria, ²Department of Clinical Pharmacology, Medical University Vienna, Vienna, Austria

The distribution of workload between GM and SOL during plantar flexion exercise is strongly linked to the knee angle. This work investigates the differences in muscle activation of GM and SOL during plantar flexion with multiple knee angles. Time series spectra of both muscle groups were acquired simultaneously with high time resolution using dynamic multi-voxel ^{31}P MRS. A linear correlation was found between knee angle and ^{31}P MRS parameters related to muscle activation (PCr depletion, pH, PCr recovery time), confirming predominant involvement of GM with a straight knee, and increasing contributions of SOL with a bent knee.

5613

Computer 53

Optimization of Regularization Parameters of Compressed Sensing Reconstruction for Fast Phosphorus MR Spectroscopic Imaging of Human Brain.

Gokce Hale Hatay¹, Muhammed Yildirim^{1,2}, and Esin Ozturk-Isik¹¹Institute of Biomedical Engineering, Bogazici University, Istanbul, Turkey, ²Advanced Diagnostic Imaging, Philips Healthcare, Best, Netherlands

This study aims at investigating the effects of compressed sensing data acquisition and reconstruction factors for accelerated phosphorus MR spectroscopic imaging (^{31}P -MRSI). Simulated ^{31}P MRSI datasets containing healthy and tumor regions were created based on the metabolite information of brain tumor patient ^{31}P -MRSI acquired at 3T. k-space data were randomly undersampled with three different reduction factors while preserving the central portion for different noise levels, reduced datasets were reconstructed using compressed sensing by combining eleven different total variation and L1-norm penalties. Findings showed that data acquisition pattern and reconstruction parameters have a significant effect on the resultant ^{31}P -MRSI spectral quality.

Dynamic ^{31}P MR spectroscopy of fatigue in triceps surae muscles on post-poliomyelitis patients versus healthy age-matched volunteers at 3T

Xeni Deligianni^{1,2}, Tanja Haas³, Patricia Hafner⁴, Simone Schmidt⁴, Vanya Gocheva⁴, Francesco Santini^{1,2}, Oliver Bieri^{1,2}, and Dirk Fischer⁴

¹Radiology, Division of Radiological Physics, University of Basel Hospital, Basel, Switzerland, ²Biomedical Engineering, University of Basel, Basel, Switzerland, ³Radiology, Clinic for Radiology and Nuclear Medicine, University of Basel Hospital, Basel, Switzerland, ⁴Pediatric Neurology, Universitäts-Kinderspital beider Basel (UKBB), Basel, Switzerland

This study was focused on comparing the metabolism of triceps surae muscles on postpoliomyelitis patients and age-matched healthy volunteers through dynamic ³¹P spectra acquisition at 3T magnetic field. It has been suggested previously that in postpolio patients, metabolic changes are secondary to neurogenic pathways, but may influence Pi/PCr ratios. Here, it was shown that baseline PDE/PCr ratios were higher in patients. During exercise, controls performed significantly higher work and the change of Pi/PCr ratios was lower than in patients. Investigation of the correlation of Pi/PCr with the degree of the disease could be a promising clinical direction.

5615

Computer 55

Improvement in ³¹P CSI voxel tissue segmentation

Xian-Feng Shi¹, Young-Hoon Sung¹, Douglas Kondo¹, Colin Andrew Riley², and Perry Renshaw¹

¹Psychiatry, University of Utah, Salt Lake City, UT, United States, ²The Brain Institute, University of Utah, Salt Lake City, UT, United States

The aim of the present study was to test a novel method for improving the subcortical tissue segmentation results, of the anatomical brain images acquired using a ³¹P/1H dual-tuned coil. When a dual-tuned ³¹P/1H coil is utilized to perform phosphorus-31 magnetic resonance spectroscopy studies of subcortical brain regions, the resulting anatomical images suffer from both low signal-to-noise ratio, and from reduced image contrast. By registering this volume image on a second anatomical image acquired using a single-tuned, 12 channel 1H head coil, we found that the subcortical tissue segmentation accuracy was significantly improved.

Short TE PRESS-based proton observed carbon edited (POCE) ¹³C Magnetic Resonance Spectroscopy with a volumetric 1H transmitter for in vivo rat brain imaging at 7T

Chathura Kumaragamage^{1,2}, Dan Madularu^{2,3}, Axel Mathieu^{2,3}, Henk De Feyter⁴, Natasha Rajah^{2,3}, and Jamie Near^{1,2,3}

¹Biomedical Engineering, McGill University, Montreal, QC, Canada, ²Brain Imaging Centre, Douglas Mental Health University Institute, Montreal, QC, Canada, ³Department of Psychiatry, McGill University, Montreal, QC, Canada, ⁴Radiology and Biomedical Imaging, Yale University, New Haven, CT, United States

Carbon-13 (¹³C) magnetic resonance spectroscopy (MRS) remains to be the only noninvasive method capable of measuring neuroenergetics and neurotransmitter cycling in the brain in vivo [1]. However, ¹³C MRS is a challenging technique to implement, and suffers from low sensitivity. In this study we investigated a short TE (12.6 ms) PRESS localized proton observed carbon edited ¹³C MRS utilizing a volumetric resonator for proton excitation. The designed platform demonstrates high sensitivity to ¹H signals, provides excellent localization, and high resolution ¹H and ¹H-[¹³C] spectra for in vivo rat brain imaging.

5617

Computer 57

Quantitative analysis of hyperpolarized [1-¹³C]pyruvate metabolic kinetics using Bayesian Inference algorithms

Nikolaos Dikaio¹, Charlie J. Daniels², Ferdia A. Gallagher², James O'Callaghan³, David Atkinson³, and Shonit Punwani³

¹Electrical Engineering, University of Surrey, Guildford, United Kingdom, ²Radiology, University of Cambridge, ³Centre for Medical Imaging, University College London

Metabolic processes monitored by MRS precede the micro-structural changes visualised by MRI. It is well-recognised that cancer cells reprogram their metabolic pathways to meet their energy demands for abnormal proliferation. Pyruvate is produced through the breakdown of glucose in glycolysis, and is essential for providing cellular energy. Histological studies have shown increased exchange of pyruvate to lactate in prostate cancer, demonstrating a positive correlation with more aggressive disease. In regions of up-regulation of glucose metabolism, [1-¹³C] pyruvate is more readily converted to [1-¹³C]lactate, providing added value for diagnostic imaging. This work aims to robustly quantify the exchange rates between pyruvate and lactate using Bayesian Inference algorithms.

5618

Computer 58

Comparison of direct ¹³C and indirect ¹H-[¹³C] MR detection methods for the study of dynamic metabolic turnover in the human brain

Hao Chen¹, Henk M De Feyter¹, Peter B Brown¹, Douglas L Rothman¹, and Robin A de Graaf¹

¹MRRC, Yale University, New Haven, CT, United States

A wide range of direct ¹³C and indirect ¹H-[¹³C] MR detection methods exist to probe dynamic metabolic pathways in the human brain. Choosing an optimal detection method is difficult as sequence-specific features regarding spectral resolution, power requirements and sensitivity complicate a straightforward comparison. Here we combine density matrix simulations with experimentally determined values for intrinsic ¹H and ¹³C sensitivity, T₁ and T₂ relaxation and transmit efficiency to allow selection of an optimal ¹³C MR detection method for a given application and magnetic field.

5619

Computer 59

The effect of malonate, succinate, oxaloacetate and 2-deoxy-D-glucose on boar sperm metabolism using ¹³C MRS

Nurul Fadhina Ismail¹, Steven Reynolds¹, Sarah Calvert², Allan Pacey², and Martyn Paley¹

¹Academic Unit of Radiology, University of Sheffield, Sheffield, United Kingdom, ²Academic Unit of Reproductive & Developmental Medicine, University of Sheffield, Sheffield, United Kingdom

One in five young men has poor semen quality, including low motility. Studying energy metabolism may provide better understanding of sperm motility. We acquired ^{13}C Magnetic Resonance spectra of sperm incubated with ^{13}C -glucose with different concentrations of inhibitors: malonate, oxaloacetate, succinate, and 2-deoxy-D-glucose. This study examined the effect of these inhibitors on sperm lactate production and vitality, with a secondary aim to observe Krebs cycle intermediates in the MR spectrum. Glucose signal significantly decreased with increasing oxaloacetate concentration. Malonate and oxaloacetate and 2DG significantly decreased in lactate production. These inhibitors did not lead to observable ^{13}C labelled Krebs cycle intermediates.

NMR and MRS studies of the neurotoxic oligomer of α -Synuclein toward investigating its *in vivo* structure
Keika Saito¹, Mitsuhiro Takeda¹, Sosuke Yoshinaga¹, and Hiroaki Terasawa¹

¹Department of Structural BioImaging, Faculty of Life Sciences, Kumamoto University, Kumamoto, Japan

α -Synuclein (α -Syn) is an abundant protein in neurons, and changes to a neurotoxic α -helical oligomer *in vitro*. The goal of our study is to investigate the structure of the α -Syn oligomer *in vivo*, by delivering ^{13}C -labeled α -Syn into mouse brains and performing a ^{13}C CEST experiment. We report the MRS detection of the ^{13}C signals of the α -Syn monomer in an agarose gel phantom, mimicking a physiological environment. We also report that the *in vitro* oligomerization rate of α -Syn varies, depending on buffer conditions. We envisage that the CEST effect will be detected by adjusting the oligomerization kinetics of α -Syn.

Feasibility of localized, ^1H decoupled natural abundance ^{13}C -MRS of human brain at 7T using double tuned array coils and polarization transfer
Guillaume Donati¹ and Rolf Gruetter^{1,2}

¹Laboratory for Functional and Metabolic Imaging, CIBM, EPFL, Lausanne, Switzerland, ²Department of Radiology, Universities of Lausanne and Geneva, Lausanne, Geneva, Switzerland

The inherent low sensitivity of ^{13}C -MRS makes detection of natural abundance metabolites in human brain challenging. We aimed to demonstrate that double-tuned array coils are particularly well-suited for ^{13}C -MRS studies *in vivo*, as they provide high sensitivity and high transmit efficiency over a large FOV. To further enhance the SNR, DEPT sequence was used to transfer polarization from ^1H to ^{13}C , as well as WALTZ-16 ^1H -decoupling, all within FDA guidelines. Natural abundance metabolites such as glutamate, glutamine, NAA and creatine were successfully detected and decoupled in 30 minutes acquisition time, showing strong efficiency and sensitivity of our measurement setup.

Computer 62

A ^{35}Cl ToRo Resonator System for Preclinical MRI/MRS at 9.4T
Matthias Malzacher¹, Ruomin Hu¹, Jorge Chacon-Caldera¹, Andreas Neubauer¹, and Lothar R Schad¹

¹Computer Assisted Clinical Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany

Chloride (Cl^-) is next to the cations Na^+ and K^+ the most abundant non-organic anion in the mammals. Assessment of chlorine's (^{35}Cl) concentration in tissue could provide further insights into tissue viability in addition to tissue sodium concentration. Yet, low Signal-to-Noise ratio (SNR) is challenging for the RF hardware components. To overcome these challenges, a Transmit-only-Receive-only (ToRo) system for ^{35}Cl MRI/MRS at 9.4T was developed comprised of an actively-decoupled linearly-driven 16 leg low-pass Birdcage transmitter coil combined with two different receiver coils. Substantial SNR gain was reached using receive-only elements compared to the Birdcage coil in TxRx mode.

Computer 64

Design and construction of a novel double-tuned $^1\text{H}/^{19}\text{F}$ coil using PIN-diode switches at 9.4T
Chang-Hoon Choi¹, Suk-Min Hong¹, YongHyun Ha¹, and N. Jon Shah^{1,2}

¹Institute of Neuroscience and Medicine-4, Forschungszentrum Juelich, Juelich, Germany, ²Faculty of Medicine, Department of Neurology, JARA, RWTH Aachen University, Aachen, Germany

A double-tuned $^1\text{H}/^{19}\text{F}$ coil using PIN-diode switches was developed and evaluated its performance on a 9.4T preclinical MRI scanner. This proposed design uses an inductor rather than a capacitor in series with the PIN-diode so that the resonance frequency is shifted in the opposite direction compared to the conventional method. This is a key difference from the previous developments and in this way we can maintain the SNR or image quality of the X-nuclei (therefore ^{19}F); the SNR is nearly as good as a single-tuned ^{19}F coil.

Study of MR characteristics of anti-psychotic drugs using fluorine (^{19}F) MR spectroscopy at 9.4 T
Chu-Yu Lee¹, In-Young Choi^{1,2,3}, Jean C Dinh⁴, William M Brooks^{1,2}, J. Steven Leeder^{4,5}, and Phil Lee^{1,3}

¹Hoglund Brain Imaging Center, University of Kansas Medical Center, Kansas City, KS, United States, ²Department of Neurology, University of Kansas Medical Center, Kansas City, KS, United States, ³Department of Molecular & Integrative Physiology, University of Kansas Medical Center, Kansas City, KS, United States, ⁴Division of Clinical Pharmacology, Toxicology, and Therapeutic Innovation, Children's Mercy Hospital, Kansas City, MO, United States, ⁵Department of Pediatrics, Children's Mercy Hospital, Kansas City, MO, United States

¹⁹F MRS allows assessment of fluorine containing anti-psychotic drugs in the brain. However, the reliable quantification remains challenging due to low drug concentrations and MR characteristics of the drugs are not well understood. This study aimed to characterize MR properties of four anti-psychotic drugs: pimoziide, paliperidone, risperidone, and racemic fluoxetine, in phantoms at 9.4 T. Our results demonstrated that pimoziide, paliperidone and risperidone showed over 50 ppm differences in chemical shifts and over 200 ms differences in T1 and T2 relaxation times compared with racemic fluoxetine. These different MR characteristics may have important implications for the ¹⁹F MRS technique development.

5626

Computer 66

Monitoring of cell proliferation by ¹⁹F-MRS via quantitation of 3'-deoxy-3'-fluorothymidine (FLT) and its monophosphate metabolite (FLT-MP) in vivo

Inok Ko¹, Ki-Hye Jung¹, Kyung Jun Kang¹, Kyo Chul Lee¹, Yong Jin Lee¹, Jung-Young Kim¹, Sang Moo Lim², and Ji-Ae Park¹

¹Division of RI-Convergence Research, Korea Institute Radiological and Medical Sciences, Seoul, Korea, Republic of, ²Department of Nuclear Medicine, Korea Institute Radiological and Medical Sciences, Seoul, Korea, Republic of

Distinguishing between FLT (fluorothymidine) and FLT-MP (fluorothymidine - monophosphate) by imaging methods is important for evaluating the tumor cell proliferation rate. The aim of this study is to develop and validate a suitable ¹⁹F MR Spectroscopy for measuring TK1 activity via quantitation of FLT and FLT-MP in vivo. We observed the good correlations between SNR and FLT concentration ($r^2 = 0.94$). In phantom study, the locations of FLT and FLT-MP was -175.99, -175.24 ppm, respectively. *In vivo* study, FLT spectrum in mouse tumor was observed in 25 min after injection, whereas FLT-MP spectrum occurred in 90 min after injection. This result shows that ¹⁹F MR Spectroscopy is suitable for monitoring of FLT-MP generation in *in vivo*.

Realistic simulation of ²³Na brain data: Understanding the influence of acquisition parameters on the accuracy of ²³Na concentration measurement

Jonathan M. Lommen¹, Nicolas G.R. Behl¹, Peter Bachert¹, Mark E. Ladd¹, and Armin M. Nagel^{1,2}

¹Medical Physics in Radiology, German Cancer Research Center (DKFZ), Heidelberg, Germany, ²Institute of Radiology, University Hospital Erlangen, Erlangen, Germany

Sodium (²³Na) is connected to tissue physiology and can be spatially resolved by MRI. Low in-vivo concentrations and short relaxation times render a quantitative determination challenging. We present a simulation method which allows synthesizing realistic ²³Na MRI raw data. Thereby, most effects in typical quantification experiments on the basis of an external concentration reference can be studied. To establish a reference accuracy level, we investigate the influence of T₂* decay, undersampling, TE, and TR on ²³Na quantification. The presented simulations can be used for the testing and evaluation of quantitative reconstruction methods as well as to test significance in clinical studies.

Interregional associations between GABA+, Glx and BOLD contrast changes during acute pain perception in the human brain – A combined 1H fMRS and fMRI study

Marianne Cleve¹, Alexander Gussev¹, Gerd Wagner², and Jürgen R. Reichenbach¹

¹Medical Physics Group, Institute of Diagnostic and Interventional Radiology, Jena University Hospital - Friedrich Schiller University Jena, Jena, Germany, ²Psychiatric Brain & Body Research Group Jena, Department of Psychiatry and Psychotherapy, Jena University Hospital, Jena, Germany

Possible associations between BOLD and left insular GABA+/tCr and Glx/tCr levels were investigated by conducting whole brain fMRI measurements and 1H MEGA-PRESS MRS at 3 T in healthy subjects prior to and during acute pain stimulation. A significant negative correlation between insular resting state GABA+/tCr levels and BOLD response was obtained in the supplementary motor area with transition to the mid-cingulate cortex. Furthermore, insular ΔGlx revealed a significant positive association with BOLD signal in the left anterior and right posterior insula. These findings suggest interregional interrelations between metabolite levels and stimulus induced BOLD response in the pain processing network.

Abnormal developmental trajectories of brain metabolites contributed to abnormal muscle tone development in infants with prenatal methamphetamine and tobacco-exposure

Linda Chang¹, Sara Hayama¹, Steven Buchthal¹, Chathura Siriwardhana¹, Daniel Alicata¹, Zachary Pang¹, Tricia Wright¹, Jon Skranes², and Thomas Ernst¹

¹University of Hawaii at Manoa, Honolulu, HI, United States, ²Pediatrics, Sorlandet Hospital, Arendal, Norway

In prior studies, children with prenatal methamphetamine-(PME) or tobacco-exposure (PTE) showed elevated brain metabolites levels. The current study evaluated infants with PME and PTE during the first 5 months of life and found abnormal developmental trajectories of metabolites in the frontal white matter, with abnormally lower levels of total creatine [tCr], N-acetylaspartate [NAA], and glutamate+glutamine [Glx] at baseline, and steeper developmental trajectories that resulted in normal or elevated levels after 2-months old. Furthermore, the trajectories of basal ganglia-[NAA] and corticospinal tract-[tCr] further contributed to the slower muscle tone development in PME infants, especially the males.

Computer 75

Neurochemical alterations in the hippocampus induced by high-fat diet: In vivo magnetic resonance spectroscopy

Song-I Lim^{1,2}, Kyu-Ho Song¹, Chi-Hyeon Yoo¹, Dong-Choel Woo², and Bo-Young Choe¹

¹Department of Biomedical Engineering, and Research Institute of Biomedical Engineering, The Catholic University of Korea College of Medicine, Seoul, Korea, Republic of, ²Asan Institute for Life Sciences, Asan Medical Center, Seoul, Korea, Republic of

In this study, we investigated the neurochemical alterations in mouse hippocampus using *in vivo* proton magnetic resonance spectroscopy. We also examine the effect of high-fat diet on the levels of abdominal fat, plasma leptin, and corticosterone. The decrease in mInS concentration seen in HF diet mice without corresponding Gln-Glu alternation may reflect changes in glial function. In addition, the observed total choline levels indicate attenuated membrane turnover in HF diet mice. We therefore suggest that diets rich in saturated fats induce a stress-related response through metabolic disturbance and HPA axis dysfunction, which may indicate a relationship between obesity and depression.

Computer 76

Reliability of *in vivo* GLX measurements from GABA-edited MRS at 3T

Elodie Boudes^{1,2}, Rachelle S Loo^{1,2}, Kari AL Parsons^{1,2}, Gareth J Barker³, David Lythgoe³, Richard AE Edden^{4,5}, R Marc Lebel⁶, Martin P Wilson⁷, and Ashley D Harris^{1,2}

¹Radiology, University of Calgary, Calgary, AB, Canada, ²CAIR Program, Alberta Children's Hospital Research Institute and Hotchkiss Brain Institute, University of Calgary, ³Department of Neuroimaging, Institute of Psychiatry, Psychology & Neuroscience, King's College London, ⁴Radiology, The Johns Hopkins School of Medicine, ⁵F. M. Kirby Research Center for Functional Brain Imaging, Kennedy Krieger Institute, ⁶General Electric Healthcare, ⁷School of Psychology, University of Birmingham

Mixed glutamate/glutamine (GLX) signal contributes to spectra acquired for GABA editing, both as a co-edited peak in the difference spectrum and in the OFF subspectrum. GLX results are often included in GABA studies, but the reliability of these metrics has received little attention. In this study, we examine the relationship between GLX measures, using a short-TE PRESS as a "gold standard", and comparing GLX measured from the co-edited peak and the OFF subspectrum from typical GABA+ and macromolecule-suppressed GABA acquisitions.

Prognostic utility of cervicovaginal fluid acetate-glutamate ratio for risk of preterm delivery within two weeks of presentation with symptoms of threatened preterm labour

Emmanuel Amabebe¹, Steven Reynolds², Victoria Stern¹, Graham Stafford³, Martyn Paley², and Dilly Anumba¹

¹Academic unit of Reproductive and Developmental Medicine, University of Sheffield, Sheffield, United Kingdom, ²Academic unit of Radiology, University of Sheffield, Sheffield, United Kingdom, ³School of Clinical Dentistry, University of Sheffield, Sheffield, United Kingdom

Accurate identification of pregnant women with symptoms of preterm labor (PTL) most likely to deliver prematurely soon after presentation/assessment is crucial for prompt clinical decision making and allocation of scarce resources by minimizing unnecessary hospitalizations and treatments, as well as by triaging patients to the centers with optimal care facilities. We determined the predictive capacity of cervicovaginal fluid (CVF) acetate/glutamate ratio in pregnant women presenting with symptoms of threatened PTL using ¹H-NMR. The ratio of CVF acetate to glutamate demonstrated better prediction of delivery within 2 weeks of symptomatic presentation, compared to either acetate or glutamate alone.

Mapping brain macromolecules in patients with multiple sclerosis using 1H-MRSI at 7T

Michal Považan^{1,2}, Eva Heckova¹, Gilbert Hangel¹, Bernhard Strasser¹, Stephan Gruber¹, Assunta Dal-Bianco³, Fritz Leutmezer³, Siegfried Trattnig^{1,2}, and Wolfgang Bogner^{1,2}

¹Department of Biomedical Imaging and Image-guided Therapy, High Field MR Centre, Medical University Vienna, Vienna, Austria, ²Christian Doppler Laboratory for Clinical Molecular MR Imaging, Vienna, Austria, ³Department of Neurology, Medical University Vienna, Vienna, Austria

Multiple sclerosis (MS) is a disease of the central nervous system associated with demyelination and glial activation affecting large areas of white matter. ¹H-MRSI may detect the metabolic changes induced by MS and facilitate the differentiation between MS lesions. Our study aimed to detect and map the signal of macromolecules in healthy controls and MS patients. 2D FID-based ¹H-MRSI was used with measurement time under 6 minutes. We found increased macromolecules in the perilesional region and decreased macromolecules in most of the lesions. However, in some lesions, macromolecules were increased, which may be possibly related to pathological activation of lesion.

A recently implemented 5D echo-planar J-resolved spectroscopic sequence using 8x acceleration and compressed sensing reconstruction was evaluated in 7 perinatally infected and 8 healthy youths. Selected metabolite ratios with respect to Cr were detected bilaterally in the basal ganglia, anterior insular cortex, posterior insular cortex, frontal white and occipital/frontal gray regions of the two groups. Statistically significant differences were found between metabolite ratios (/Cr) of HIV-infected young adults and healthy control subjects in the occipital gray N-acetylaspartate, right basal ganglia glutamine/glutamate, left anterior insular cortex choline, and left posterior insular cortex. Also, our pilot findings suggest a possible difference in energy metabolism between perinatally HIV-infected young adults and controls without HIV. The metabolite ratios correlated with neuropsychological test scores showing cognitive impairment as result of HIV-infection and/or long term ART.

Can we predict the chemotherapy outcomes and efficacy - metabolomics approach for predicting response to anticancer drugs: in vitro ¹H MRS of living human melanoma and bladder carcinoma at 9.4T

Katarzyna Pierzchala¹, Nicolas Kunz¹, and Rolf Gruetter¹

¹Center for Biomedical Imaging, EPFL / CIBM, Lausanne, Switzerland

The number of patients diagnosed with cancer is increasing. Therefore the ability to predict tumor response to therapeutic agents remains a major challenge. Tumor cell metabolism is currently examined by ¹H MRS with the aim of getting more insight into the differences between normal and neoplastic tissues, characterize their metastatic potential/finding prognostic markers, and monitoring the effect of therapies. In this study we demonstrate the feasibility of characterizing in-vitro living cells and present changes in the metabolic profile of WM793 and T24 cells subjected to chemotherapy. These results show promise for more personalized treatment protocols for cancer patients.

5644

Computer 84

Improving the detection of scalar-coupled resonances at short and moderate echo times for in vivo rat MRS at 9.4 T

Liangjie Lin^{1,2,3}, Yanqin Lin¹, Dan Tian¹, Hongyi Yang⁴, Zhiliang Wei^{2,3}, Peter B. Barker^{2,3}, Kai Zhong⁴, and Zhong Chen¹

¹Department of Electronic Science, Xiamen University, Xiamen, People's Republic of China, ²Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins University, Baltimore, MD, United States, ³F. M. Kirby Center for Functional Brain Imaging, Kennedy Krieger Institute, Baltimore, MD, United States, ⁴High Magnetic Field Laboratory, CAS Center for Excellence in Brain Science, Chinese Academy of Sciences, Hefei, People's Republic of China

Conventional localized ¹H MRS pulse sequences, such as PRESS and STEAM, generally suffer from J coupling modulations which can aggravate attenuation of multiplet resonances during echo times. Here, the "perfect echo" module combined with an optimized localization scheme is utilized for in-phase single-voxel in vivo MRS at 9.4 T. The relative signal intensities of multiplet to singlet resonances acquired at short and moderate echo times increase substantially in comparison with those at PRESS spectra. Therefore, direct MRS quantification of many important metabolites, such as glutamine, glutamate, γ-aminobutyrate, aspartate, and myo-inositol, may be improved.

The subjective intensity of pain in healthy subjects is inversely correlate with posterior insular GABA levels

Margot Thiaucourt¹, Polina Shabes², Natalie Schloss³, Markus Sack¹, Ulf Baumgaertner², Christian Schmahl³, and Gabriele Ende¹

¹Neuroimaging, Central Institute of Mental Health, Mannheim, Germany, ²Center for Biomedicine and Medical Technology Mannheim, Medical Faculty Mannheim, Mannheim, Germany, ³Psychosomatic Medicine and Psychotherapy, Central Institute of Mental Health, Mannheim, Germany

We present single voxel MEGA-PRESS MRS data from the posterior insula of 20 healthy women demonstrating a significant association of GABA and the subjective pain thresholds. These findings are in good agreement with the postulated role of the posterior insula for pain information processing. In this region pain is first processed and the sensory aspects of pain perception is elaborated and then conveyed to the anterior insula where it is related to emotional and cognitive aspects of pain perception. The data corroborate that GABA levels seem to be an important mediator for pain perception.

¹Translational Research Institute, Woolloongabba, Australia, ²Centre for Advanced Imaging, The University of Queensland, Brisbane, Australia, ³University of Newcastle, Australia, ⁴Institute for Health and Biomedical Innovation, Brisbane, Australia, ⁵Department of Defence, Australian Government, Sydney, Australia

This pilot study reports clear deregulation in the neurochemistry of defense personnel exposed to repeated blast. The changes recorded are different to those reported for mTBI, PTSD and chronic pain. No differences between blast exposed and healthy were recorded by MRI sequences T1WI, FLAIR or SWI. In vivo neuro 2D spectroscopy recorded deregulation with PC and GPC, NAA and GABA all decreased compared to the healthy non exposed brain. We did not observe any changes in the fucosylated glycans, which are reflective of pain, repetitive brain injury and/or cognitive deficit.

7T Brain MRS in HIV Infection: Effects of Cognitive Impairment

Mona A Mohamed¹, Peter B Barker¹, Richard Skolasky², and Ned C Sacktor³

¹Radiology, Johns Hopkins Medical Institutions, Baltimore, MD, United States, ²Orthopedic, Johns Hopkins Medical Institutions, Baltimore, MD, United States, ³Neurology, Johns Hopkins Medical Institutions, Baltimore, MD, United States

Higher magnetic field such as 7T provides increased sensitivity, better signal to noise ratio and more reliable measure of the metabolite concentrations. In this study, 7T MRS was used to measure brain metabolites in HIV+ patients in 5 brain regions. Our study showed impaired neuronal integrity across the white and gray matter as well as possible impaired astrocyte osmoregulation in patients with symptomatic cognitive impairment. In conclusion, 7T MRS brain metabolites measurement can be used as reliable biomarkers for the assessment of cognitive status in HIV+ patients.

J. Gorter Center for High Field MRI, Department of Radiology, Leiden University Medical Center, Leiden, Netherlands

Diffusion-weighted ¹H magnetic resonance spectroscopy (DW-MRS) probes the diffusion properties of metabolites, which are differentially compartmentalized in brain tissue and are thus more specific than water molecules to the intra-cellular environment. The aim of this study was to measure water and metabolite diffusion in the human brain in the acute, sub-acute and chronic stage of ischemic stroke, in order to better characterize the microstructural dynamic changes ongoing at different stages of the disease, in both infarcted and peripheral regions, by disentangling neuronal, glial and extra-cellular pathological processes.

Enhanced detection of weak metabolites with short initial echo time 2D L-COSY

Jameen ARM¹, Karen Ribbons², Jeannette Lechner-Scott³, Kate Skehan⁴, Shiami Luchow³, M. Albert Thomas⁵, and Saadallah Ramadan⁶

¹University of Newcastle, Newcastle, Australia, ²John Hunter Hospital, Australia, ³Hunter Medical Research Institute, Australia, ⁴HMRI Imaging centre, Hunter Medical Research Institute, Australia, ⁵University of California Los Angeles, CA, United States, ⁶University of Newcastle, Australia

The detection of weak neurometabolites such as g-aminobutyric acid (GABA), glutathione (GSH), glycerophosphocholine (GPC), phosphorylethanolamine (PE) with 2D L-COSY can be challenging due to lower concentrations. Moreover, the standard initial echo time ($TE_{initial}$) of 30ms yields suboptimal SNR due to shorter T_2^* . In this study, we compared short $TE_{initial}$ of 20ms vs 30ms to evaluate improved detection of low concentration metabolites. Our results show a significant increase in SNR with $TE_{initial}$ of 20ms compared to 30ms. Short $TE_{initial}$ of 20ms has increased potential in the detection of peaks from weak neurometabolites.

Investigation of long-term effect of a high-fat diet using quantitative MRI and 1H MRS for assessing body and liver fat, and muscle mass

Jong-Hee Hwang¹, In-Young Lee², Jung-Hyun Kim², and Jae Seung Kim²

¹Institute for Clinical Diabetology, German Diabetes Center, Leibniz Institute for Diabetes Research, Heinrich Heine University, Düsseldorf, Germany, ²Lee Gil Ya Cancer and Diabetes Institute, Gachon University, Incheon, Korea, Republic of

Repetitive and noninvasive MR examinations of fat content can provide indispensable information for longitudinal metabolic studies. It is of great interest to understand how obesity in youth affects the fat metabolism later in life. Thus we longitudinally examined mice with/without a high-fat diet [HFD] for 8 weeks from 13 to 67 weeks old using MRI and 1H MRS. As a result, visceral fat restored normalcy in 10 weeks after the termination of HFD, subcutaneous and liver fat returned to normalcy in ~ 16 - 20 weeks as compared to controls.
